Note that the user performing the insert, update or delete on the view must have the corresponding insert, update or delete privilege on the view. In addition the view's owner must have the relevant privileges on the underlying base relations, but the user performing the update does not need any permissions on the underlying base relations (see [Section 38.5](#)).

## Examples

Create a view consisting of all comedy films:

```
CREATE VIEW comedies AS
  SELECT *
  FROM films
  WHERE kind = 'Comedy';
```

This will create a view containing the columns that are in the `film` table at the time of view creation. Though `*` was used to create the view, columns added later to the table will not be part of the view.

Create a view with `LOCAL CHECK OPTION`:

```
CREATE VIEW universal_comedies AS
  SELECT *
  FROM comedies
  WHERE classification = 'U'
  WITH LOCAL CHECK OPTION;
```

This will create a view based on the `comedies` view, showing only films with `kind = 'Comedy'` and `classification = 'U'`. Any attempt to `INSERT` or `UPDATE` a row in the view will be rejected if the new row doesn't have `classification = 'U'`, but the `film kind` will not be checked.

Create a view with `CASCADED CHECK OPTION`:

```
CREATE VIEW pg_comedies AS
  SELECT *
  FROM comedies
  WHERE classification = 'PG'
  WITH CASCADED CHECK OPTION;
```

This will create a view that checks both the `kind` and `classification` of new rows.

Create a view with a mix of updatable and non-updatable columns:

```
CREATE VIEW comedies AS
  SELECT f.*,
         country_code_to_name(f.country_code) AS country,
         (SELECT avg(r.rating)
          FROM user_ratings r
          WHERE r.film_id = f.id) AS avg_rating
  FROM films f
  WHERE f.kind = 'Comedy';
```

This view will support `INSERT`, `UPDATE` and `DELETE`. All the columns from the `films` table will be updatable, whereas the computed columns `country` and `avg_rating` will be read-only.

Create a recursive view consisting of the numbers from 1 to 100:

```
CREATE RECURSIVE VIEW public.nums_1_100 (n) AS
  VALUES (1)
 UNION ALL
  SELECT n+1 FROM nums_1_100 WHERE n < 100;
```

Notice that although the recursive view's name is schema-qualified in this `CREATE`, its internal self-reference is not schema-qualified. This is because the implicitly-created CTE's name cannot be schema-qualified.

## Compatibility

`CREATE OR REPLACE VIEW` is a Postgres Pro language extension. So is the concept of a temporary view. The `WITH ( ... )` clause is an extension as well.

## See Also

[ALTER VIEW](#), [DROP VIEW](#), [CREATE MATERIALIZED VIEW](#)

---

# DEALLOCATE

DEALLOCATE — deallocate a prepared statement

## Synopsis

```
DEALLOCATE [ PREPARE ] { name | ALL }
```

## Description

DEALLOCATE is used to deallocate a previously prepared SQL statement. If you do not explicitly deallocate a prepared statement, it is deallocated when the session ends.

For more information on prepared statements, see [PREPARE](#).

## Parameters

PREPARE

This key word is ignored.

*name*

The name of the prepared statement to deallocate.

ALL

Deallocate all prepared statements.

## Compatibility

The SQL standard includes a DEALLOCATE statement, but it is only for use in embedded SQL.

## See Also

[EXECUTE](#), [PREPARE](#)

---

# DECLARE

DECLARE — define a cursor

## Synopsis

```
DECLARE name [ BINARY ] [ INSENSITIVE ] [ [ NO ] SCROLL ]  
        CURSOR [ { WITH | WITHOUT } HOLD ] FOR query
```

## Description

DECLARE allows a user to create cursors, which can be used to retrieve a small number of rows at a time out of a larger query. After the cursor is created, rows are fetched from it using [FETCH](#).

### Note

This page describes usage of cursors at the SQL command level. If you are trying to use cursors inside a PL/pgSQL function, the rules are different — see [Section 40.7](#).

## Parameters

*name*

The name of the cursor to be created.

BINARY

Causes the cursor to return data in binary rather than in text format.

INSENSITIVE

Indicates that data retrieved from the cursor should be unaffected by updates to the table(s) underlying the cursor that occur after the cursor is created. In Postgres Pro, this is the default behavior; so this key word has no effect and is only accepted for compatibility with the SQL standard.

SCROLL

NO SCROLL

SCROLL specifies that the cursor can be used to retrieve rows in a nonsequential fashion (e.g., backward). Depending upon the complexity of the query's execution plan, specifying SCROLL might impose a performance penalty on the query's execution time. NO SCROLL specifies that the cursor cannot be used to retrieve rows in a nonsequential fashion. The default is to allow scrolling in some cases; this is not the same as specifying SCROLL. See [Notes](#) below for details.

WITH HOLD

WITHOUT HOLD

WITH HOLD specifies that the cursor can continue to be used after the transaction that created it successfully commits. WITHOUT HOLD specifies that the cursor cannot be used outside of the transaction that created it. If neither WITHOUT HOLD nor WITH HOLD is specified, WITHOUT HOLD is the default.

*query*

A [SELECT](#) or [VALUES](#) command which will provide the rows to be returned by the cursor.

The key words BINARY, INSENSITIVE, and SCROLL can appear in any order.

## Notes

Normal cursors return data in text format, the same as a `SELECT` would produce. The `BINARY` option specifies that the cursor should return data in binary format. This reduces conversion effort for both the server and client, at the cost of more programmer effort to deal with platform-dependent binary data formats. As an example, if a query returns a value of one from an integer column, you would get a string of 1 with a default cursor, whereas with a binary cursor you would get a 4-byte field containing the internal representation of the value (in big-endian byte order).

Binary cursors should be used carefully. Many applications, including `psql`, are not prepared to handle binary cursors and expect data to come back in the text format.

### Note

When the client application uses the “extended query” protocol to issue a `FETCH` command, the `Bind` protocol message specifies whether data is to be retrieved in text or binary format. This choice overrides the way that the cursor is defined. The concept of a binary cursor as such is thus obsolete when using extended query protocol — any cursor can be treated as either text or binary.

Unless `WITH HOLD` is specified, the cursor created by this command can only be used within the current transaction. Thus, `DECLARE` without `WITH HOLD` is useless outside a transaction block: the cursor would survive only to the completion of the statement. Therefore Postgres Pro reports an error if such a command is used outside a transaction block. Use `BEGIN` and `COMMIT` (or `ROLLBACK`) to define a transaction block.

If `WITH HOLD` is specified and the transaction that created the cursor successfully commits, the cursor can continue to be accessed by subsequent transactions in the same session. (But if the creating transaction is aborted, the cursor is removed.) A cursor created with `WITH HOLD` is closed when an explicit `CLOSE` command is issued on it, or the session ends. In the current implementation, the rows represented by a held cursor are copied into a temporary file or memory area so that they remain available for subsequent transactions.

`WITH HOLD` may not be specified when the query includes `FOR UPDATE` or `FOR SHARE`.

The `SCROLL` option should be specified when defining a cursor that will be used to fetch backwards. This is required by the SQL standard. However, for compatibility with earlier versions, Postgres Pro will allow backward fetches without `SCROLL`, if the cursor's query plan is simple enough that no extra overhead is needed to support it. However, application developers are advised not to rely on using backward fetches from a cursor that has not been created with `SCROLL`. If `NO SCROLL` is specified, then backward fetches are disallowed in any case.

Backward fetches are also disallowed when the query includes `FOR UPDATE` or `FOR SHARE`; therefore `SCROLL` may not be specified in this case.

### Caution

Scrollable cursors may give unexpected results if they invoke any volatile functions (see [Section 35.7](#)). When a previously fetched row is re-fetched, the functions might be re-executed, perhaps leading to results different from the first time. It's best to specify `NO SCROLL` for a query involving volatile functions. If that is not practical, one workaround is to declare the cursor `SCROLL WITH HOLD` and commit the transaction before reading any rows from it. This will force the entire output of the cursor to be materialized in temporary storage, so that volatile functions are executed exactly once for each row.

If the cursor's query includes `FOR UPDATE` or `FOR SHARE`, then returned rows are locked at the time they are first fetched, in the same way as for a regular `SELECT` command with these options. In addition,

the returned rows will be the most up-to-date versions; therefore these options provide the equivalent of what the SQL standard calls a “sensitive cursor”. (Specifying `INSENSITIVE` together with `FOR UPDATE` or `FOR SHARE` is an error.)

### Caution

It is generally recommended to use `FOR UPDATE` if the cursor is intended to be used with `UPDATE . . . WHERE CURRENT OF` or `DELETE . . . WHERE CURRENT OF`. Using `FOR UPDATE` prevents other sessions from changing the rows between the time they are fetched and the time they are updated. Without `FOR UPDATE`, a subsequent `WHERE CURRENT OF` command will have no effect if the row was changed since the cursor was created.

Another reason to use `FOR UPDATE` is that without it, a subsequent `WHERE CURRENT OF` might fail if the cursor query does not meet the SQL standard's rules for being “simply updatable” (in particular, the cursor must reference just one table and not use grouping or `ORDER BY`). Cursors that are not simply updatable might work, or might not, depending on plan choice details; so in the worst case, an application might work in testing and then fail in production. If `FOR UPDATE` is specified, the cursor is guaranteed to be updatable.

The main reason not to use `FOR UPDATE` with `WHERE CURRENT OF` is if you need the cursor to be scrollable, or to be insensitive to the subsequent updates (that is, continue to show the old data). If this is a requirement, pay close heed to the caveats shown above.

The SQL standard only makes provisions for cursors in embedded SQL. The Postgres Pro server does not implement an `OPEN` statement for cursors; a cursor is considered to be open when it is declared. However, ECPG, the embedded SQL preprocessor for Postgres Pro, supports the standard SQL cursor conventions, including those involving `DECLARE` and `OPEN` statements.

You can see all available cursors by querying the `pg_cursors` system view.

## Examples

To declare a cursor:

```
DECLARE liahona CURSOR FOR SELECT * FROM films;
```

See [FETCH](#) for more examples of cursor usage.

## Compatibility

The SQL standard says that it is implementation-dependent whether cursors are sensitive to concurrent updates of the underlying data by default. In Postgres Pro, cursors are insensitive by default, and can be made sensitive by specifying `FOR UPDATE`. Other products may work differently.

The SQL standard allows cursors only in embedded SQL and in modules. Postgres Pro permits cursors to be used interactively.

Binary cursors are a Postgres Pro extension.

---

# DELETE

DELETE — delete rows of a table

## Synopsis

```
[ WITH [ RECURSIVE ] with_query [, ...] ]  
DELETE FROM [ ONLY ] table_name [ * ] [ [ AS ] alias ]  
  [ USING from_item [, ...] ]  
  [ WHERE condition | WHERE CURRENT OF cursor_name ]  
  [ RETURNING * | output_expression [ [ AS ] output_name ] [, ...] ]
```

## Description

DELETE deletes rows that satisfy the WHERE clause from the specified table. If the WHERE clause is absent, the effect is to delete all rows in the table. The result is a valid, but empty table.

### Tip

**TRUNCATE** provides a faster mechanism to remove all rows from a table.

There are two ways to delete rows in a table using information contained in other tables in the database: using sub-selects, or specifying additional tables in the USING clause. Which technique is more appropriate depends on the specific circumstances.

The optional RETURNING clause causes DELETE to compute and return value(s) based on each row actually deleted. Any expression using the table's columns, and/or columns of other tables mentioned in USING, can be computed. The syntax of the RETURNING list is identical to that of the output list of SELECT.

You must have the DELETE privilege on the table to delete from it, as well as the SELECT privilege for any table in the USING clause or whose values are read in the *condition*.

## Parameters

*with\_query*

The WITH clause allows you to specify one or more subqueries that can be referenced by name in the DELETE query. See [Section 7.8](#) and [SELECT](#) for details.

*table\_name*

The name (optionally schema-qualified) of the table to delete rows from. If ONLY is specified before the table name, matching rows are deleted from the named table only. If ONLY is not specified, matching rows are also deleted from any tables inheriting from the named table. Optionally, \* can be specified after the table name to explicitly indicate that descendant tables are included.

*alias*

A substitute name for the target table. When an alias is provided, it completely hides the actual name of the table. For example, given DELETE FROM foo AS f, the remainder of the DELETE statement must refer to this table as f not foo.

*from\_item*

A table expression allowing columns from other tables to appear in the WHERE condition. This uses the same syntax as the FROM clause of a SELECT statement; for example, an alias for the table name can be specified. Do not repeat the target table as a *from\_item* unless you wish to set up a self-join (in which case it must appear with an alias in the *from\_item*).

*condition*

An expression that returns a value of type `boolean`. Only rows for which this expression returns `true` will be deleted.

*cursor\_name*

The name of the cursor to use in a `WHERE CURRENT OF` condition. The row to be deleted is the one most recently fetched from this cursor. The cursor must be a non-grouping query on the `DELETE`'s target table. Note that `WHERE CURRENT OF` cannot be specified together with a Boolean condition. See [DECLARE](#) for more information about using cursors with `WHERE CURRENT OF`.

*output\_expression*

An expression to be computed and returned by the `DELETE` command after each row is deleted. The expression can use any column names of the table named by *table\_name* or table(s) listed in `USING`. Write `*` to return all columns.

*output\_name*

A name to use for a returned column.

## Outputs

On successful completion, a `DELETE` command returns a command tag of the form

```
DELETE count
```

The *count* is the number of rows deleted. Note that the number may be less than the number of rows that matched the *condition* when deletes were suppressed by a `BEFORE DELETE` trigger. If *count* is 0, no rows were deleted by the query (this is not considered an error).

If the `DELETE` command contains a `RETURNING` clause, the result will be similar to that of a `SELECT` statement containing the columns and values defined in the `RETURNING` list, computed over the row(s) deleted by the command.

## Notes

Postgres Pro lets you reference columns of other tables in the `WHERE` condition by specifying the other tables in the `USING` clause. For example, to delete all films produced by a given producer, one can do:

```
DELETE FROM films USING producers
WHERE producer_id = producers.id AND producers.name = 'foo';
```

What is essentially happening here is a join between `films` and `producers`, with all successfully joined `films` rows being marked for deletion. This syntax is not standard. A more standard way to do it is:

```
DELETE FROM films
WHERE producer_id IN (SELECT id FROM producers WHERE name = 'foo');
```

In some cases the join style is easier to write or faster to execute than the sub-select style.

## Examples

Delete all films but musicals:

```
DELETE FROM films WHERE kind <> 'Musical';
```

Clear the table `films`:

```
DELETE FROM films;
```

Delete completed tasks, returning full details of the deleted rows:

```
DELETE FROM tasks WHERE status = 'DONE' RETURNING *;
```

Delete the row of `tasks` on which the cursor `c_tasks` is currently positioned:

```
DELETE FROM tasks WHERE CURRENT OF c_tasks;
```

### Compatibility

This command conforms to the SQL standard, except that the `USING` and `RETURNING` clauses are Postgres Pro extensions, as is the ability to use `WITH` with `DELETE`.

### See Also

[TRUNCATE](#)

---

# DISCARD

DISCARD — discard session state

## Synopsis

```
DISCARD { ALL | PLANS | SEQUENCES | TEMPORARY | TEMP }
```

## Description

DISCARD releases internal resources associated with a database session. This command is useful for partially or fully resetting the session's state. There are several subcommands to release different types of resources; the DISCARD ALL variant subsumes all the others, and also resets additional state.

## Parameters

PLANS

Releases all cached query plans, forcing re-planning to occur the next time the associated prepared statement is used.

SEQUENCES

Discards all cached sequence-related state, including `currval()/lastval()` information and any preallocated sequence values that have not yet been returned by `nextval()`. (See [CREATE SEQUENCE](#) for a description of preallocated sequence values.)

TEMPORARY or TEMP

Drops all temporary tables created in the current session.

ALL

Releases all temporary resources associated with the current session and resets the session to its initial state. Currently, this has the same effect as executing the following sequence of statements:

```
CLOSE ALL;  
SET SESSION AUTHORIZATION DEFAULT;  
RESET ALL;  
DEALLOCATE ALL;  
UNLISTEN *;  
SELECT pg_advisory_unlock_all();  
DISCARD PLANS;  
DISCARD TEMP;  
DISCARD SEQUENCES;
```

## Notes

DISCARD ALL cannot be executed inside a transaction block.

## Compatibility

DISCARD is a Postgres Pro extension.

---

## DO

DO — execute an anonymous code block

### Synopsis

```
DO [ LANGUAGE lang_name ] code
```

### Description

DO executes an anonymous code block, or in other words a transient anonymous function in a procedural language.

The code block is treated as though it were the body of a function with no parameters, returning `void`. It is parsed and executed a single time.

The optional `LANGUAGE` clause can be written either before or after the code block.

### Parameters

*code*

The procedural language code to be executed. This must be specified as a string literal, just as in `CREATE FUNCTION`. Use of a dollar-quoted literal is recommended.

*lang\_name*

The name of the procedural language the code is written in. If omitted, the default is `plpgsql`.

### Notes

The procedural language to be used must already have been installed into the current database by means of `CREATE EXTENSION`. `plpgsql` is installed by default, but other languages are not.

The user must have `USAGE` privilege for the procedural language, or must be a superuser if the language is untrusted. This is the same privilege requirement as for creating a function in the language.

If `DO` is executed in a transaction block, then the procedure code cannot execute transaction control statements. Transaction control statements are only allowed if `DO` is executed in its own transaction.

### Examples

Grant all privileges on all views in schema `public` to role `webuser`:

```
DO $$DECLARE r record;
BEGIN
    FOR r IN SELECT table_schema, table_name FROM information_schema.tables
        WHERE table_type = 'VIEW' AND table_schema = 'public'
    LOOP
        EXECUTE 'GRANT ALL ON ' || quote_ident(r.table_schema) || '.' ||
quote_ident(r.table_name) || ' TO webuser';
    END LOOP;
END$$;
```

### Compatibility

There is no `DO` statement in the SQL standard.

### See Also

[CREATE LANGUAGE](#)

---

# DROP ACCESS METHOD

DROP ACCESS METHOD — remove an access method

## Synopsis

```
DROP ACCESS METHOD [ IF EXISTS ] name [ CASCADE | RESTRICT ]
```

## Description

DROP ACCESS METHOD removes an existing access method. Only superusers can drop access methods.

## Parameters

IF EXISTS

Do not throw an error if the access method does not exist. A notice is issued in this case.

*name*

The name of an existing access method.

CASCADE

Automatically drop objects that depend on the access method (such as operator classes, operator families, and indexes), and in turn all objects that depend on those objects (see [Section 5.14](#)).

RESTRICT

Refuse to drop the access method if any objects depend on it. This is the default.

## Examples

Drop the access method `heptree`:

```
DROP ACCESS METHOD heptree;
```

## Compatibility

DROP ACCESS METHOD is a Postgres Pro extension.

## See Also

[CREATE ACCESS METHOD](#)

---

# DROP AGGREGATE

DROP AGGREGATE — remove an aggregate function

## Synopsis

```
DROP AGGREGATE [ IF EXISTS ] name ( aggregate_signature ) [, ...] [ CASCADE |  
RESTRICT ]
```

where *aggregate\_signature* is:

```
* |  
[ argmode ] [ argname ] argtype [ , ... ] |  
[ [ argmode ] [ argname ] argtype [ , ... ] ] ORDER BY [ argmode ] [ argname ] argtype  
[ , ... ]
```

## Description

DROP AGGREGATE removes an existing aggregate function. To execute this command the current user must be the owner of the aggregate function.

## Parameters

IF EXISTS

Do not throw an error if the aggregate does not exist. A notice is issued in this case.

*name*

The name (optionally schema-qualified) of an existing aggregate function.

*argmode*

The mode of an argument: IN or VARIADIC. If omitted, the default is IN.

*argname*

The name of an argument. Note that DROP AGGREGATE does not actually pay any attention to argument names, since only the argument data types are needed to determine the aggregate function's identity.

*argtype*

An input data type on which the aggregate function operates. To reference a zero-argument aggregate function, write \* in place of the list of argument specifications. To reference an ordered-set aggregate function, write ORDER BY between the direct and aggregated argument specifications.

CASCADE

Automatically drop objects that depend on the aggregate function (such as views using it), and in turn all objects that depend on those objects (see [Section 5.14](#)).

RESTRICT

Refuse to drop the aggregate function if any objects depend on it. This is the default.

## Notes

Alternative syntaxes for referencing ordered-set aggregates are described under [ALTER AGGREGATE](#).

## Examples

To remove the aggregate function `myavg` for type `integer`:

```
DROP AGGREGATE myavg(integer);
```

To remove the hypothetical-set aggregate function `myrank`, which takes an arbitrary list of ordering columns and a matching list of direct arguments:

```
DROP AGGREGATE myrank(VARIADIC "any" ORDER BY VARIADIC "any");
```

To remove multiple aggregate functions in one command:

```
DROP AGGREGATE myavg(integer), myavg(bigint);
```

### Compatibility

There is no `DROP AGGREGATE` statement in the SQL standard.

### See Also

[ALTER AGGREGATE](#), [CREATE AGGREGATE](#)

---

# DROP CAST

DROP CAST — remove a cast

## Synopsis

```
DROP CAST [ IF EXISTS ] (source_type AS target_type) [ CASCADE | RESTRICT ]
```

## Description

DROP CAST removes a previously defined cast.

To be able to drop a cast, you must own the source or the target data type. These are the same privileges that are required to create a cast.

## Parameters

IF EXISTS

Do not throw an error if the cast does not exist. A notice is issued in this case.

*source\_type*

The name of the source data type of the cast.

*target\_type*

The name of the target data type of the cast.

CASCADE

RESTRICT

These key words do not have any effect, since there are no dependencies on casts.

## Examples

To drop the cast from type `text` to type `int`:

```
DROP CAST (text AS int);
```

## Compatibility

The DROP CAST command conforms to the SQL standard.

## See Also

[CREATE CAST](#)

---

# DROP COLLATION

DROP COLLATION — remove a collation

## Synopsis

```
DROP COLLATION [ IF EXISTS ] name [ CASCADE | RESTRICT ]
```

## Description

DROP COLLATION removes a previously defined collation. To be able to drop a collation, you must own the collation.

## Parameters

IF EXISTS

Do not throw an error if the collation does not exist. A notice is issued in this case.

*name*

The name of the collation. The collation name can be schema-qualified.

CASCADE

Automatically drop objects that depend on the collation, and in turn all objects that depend on those objects (see [Section 5.14](#)).

RESTRICT

Refuse to drop the collation if any objects depend on it. This is the default.

## Examples

To drop the collation named `german`:

```
DROP COLLATION german;
```

## Compatibility

The DROP COLLATION command conforms to the SQL standard, apart from the IF EXISTS option, which is a Postgres Pro extension.

## See Also

[ALTER COLLATION](#), [CREATE COLLATION](#)

---

# DROP CONVERSION

DROP CONVERSION — remove a conversion

## Synopsis

```
DROP CONVERSION [ IF EXISTS ] name [ CASCADE | RESTRICT ]
```

## Description

DROP CONVERSION removes a previously defined conversion. To be able to drop a conversion, you must own the conversion.

## Parameters

IF EXISTS

Do not throw an error if the conversion does not exist. A notice is issued in this case.

*name*

The name of the conversion. The conversion name can be schema-qualified.

CASCADE

RESTRICT

These key words do not have any effect, since there are no dependencies on conversions.

## Examples

To drop the conversion named *myname*:

```
DROP CONVERSION myname;
```

## Compatibility

There is no DROP CONVERSION statement in the SQL standard, but a DROP TRANSLATION statement that goes along with the CREATE TRANSLATION statement that is similar to the CREATE CONVERSION statement in Postgres Pro.

## See Also

[ALTER CONVERSION](#), [CREATE CONVERSION](#)

---

# DROP DATABASE

DROP DATABASE — remove a database

## Synopsis

```
DROP DATABASE [ IF EXISTS ] name [ [ WITH ] ( option [, ...] ) ]
```

where *option* can be:

```
FORCE
```

## Description

DROP DATABASE drops a database. It removes the catalog entries for the database and deletes the directory containing the data. It can only be executed by the database owner. It cannot be executed while you are connected to the target database. (Connect to `postgres` or any other database to issue this command.) Also, if anyone else is connected to the target database, this command will fail unless you use the `FORCE` option described below.

DROP DATABASE cannot be undone. Use it with care!

## Parameters

```
IF EXISTS
```

Do not throw an error if the database does not exist. A notice is issued in this case.

```
name
```

The name of the database to remove.

```
FORCE
```

Attempt to terminate all existing connections to the target database. It doesn't terminate if prepared transactions, active logical replication slots or subscriptions are present in the target database.

This will fail if the current user has no permissions to terminate other connections. Required permissions are the same as with `pg_terminate_backend`, described in [Section 9.27.2](#). This will also fail if we are not able to terminate connections.

## Notes

DROP DATABASE cannot be executed inside a transaction block.

This command cannot be executed while connected to the target database. Thus, it might be more convenient to use the program [dropdb](#) instead, which is a wrapper around this command.

## Compatibility

There is no DROP DATABASE statement in the SQL standard.

## See Also

[CREATE DATABASE](#)

---

# DROP DOMAIN

DROP DOMAIN — remove a domain

## Synopsis

```
DROP DOMAIN [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]
```

## Description

DROP DOMAIN removes a domain. Only the owner of a domain can remove it.

## Parameters

IF EXISTS

Do not throw an error if the domain does not exist. A notice is issued in this case.

*name*

The name (optionally schema-qualified) of an existing domain.

CASCADE

Automatically drop objects that depend on the domain (such as table columns), and in turn all objects that depend on those objects (see [Section 5.14](#)).

RESTRICT

Refuse to drop the domain if any objects depend on it. This is the default.

## Examples

To remove the domain `box`:

```
DROP DOMAIN box;
```

## Compatibility

This command conforms to the SQL standard, except for the `IF EXISTS` option, which is a Postgres Pro extension.

## See Also

[CREATE DOMAIN](#), [ALTER DOMAIN](#)

---

# DROP EVENT TRIGGER

DROP EVENT TRIGGER — remove an event trigger

## Synopsis

```
DROP EVENT TRIGGER [ IF EXISTS ] name [ CASCADE | RESTRICT ]
```

## Description

DROP EVENT TRIGGER removes an existing event trigger. To execute this command, the current user must be the owner of the event trigger.

## Parameters

IF EXISTS

Do not throw an error if the event trigger does not exist. A notice is issued in this case.

*name*

The name of the event trigger to remove.

CASCADE

Automatically drop objects that depend on the trigger, and in turn all objects that depend on those objects (see [Section 5.14](#)).

RESTRICT

Refuse to drop the trigger if any objects depend on it. This is the default.

## Examples

Destroy the trigger `snitch`:

```
DROP EVENT TRIGGER snitch;
```

## Compatibility

There is no DROP EVENT TRIGGER statement in the SQL standard.

## See Also

[CREATE EVENT TRIGGER](#), [ALTER EVENT TRIGGER](#)

---

# DROP EXTENSION

DROP EXTENSION — remove an extension

## Synopsis

```
DROP EXTENSION [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]
```

## Description

DROP EXTENSION removes extensions from the database. Dropping an extension causes its component objects to be dropped as well.

You must own the extension to use DROP EXTENSION.

## Parameters

IF EXISTS

Do not throw an error if the extension does not exist. A notice is issued in this case.

*name*

The name of an installed extension.

CASCADE

Automatically drop objects that depend on the extension, and in turn all objects that depend on those objects (see [Section 5.14](#)).

RESTRICT

Refuse to drop the extension if any objects depend on it (other than its own member objects and other extensions listed in the same DROP command). This is the default.

## Examples

To remove the extension `hstore` from the current database:

```
DROP EXTENSION hstore;
```

This command will fail if any of `hstore`'s objects are in use in the database, for example if any tables have columns of the `hstore` type. Add the `CASCADE` option to forcibly remove those dependent objects as well.

## Compatibility

DROP EXTENSION is a Postgres Pro extension.

## See Also

[CREATE EXTENSION](#), [ALTER EXTENSION](#)

---

# DROP FOREIGN DATA WRAPPER

DROP FOREIGN DATA WRAPPER — remove a foreign-data wrapper

## Synopsis

```
DROP FOREIGN DATA WRAPPER [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]
```

## Description

DROP FOREIGN DATA WRAPPER removes an existing foreign-data wrapper. To execute this command, the current user must be the owner of the foreign-data wrapper.

## Parameters

IF EXISTS

Do not throw an error if the foreign-data wrapper does not exist. A notice is issued in this case.

*name*

The name of an existing foreign-data wrapper.

CASCADE

Automatically drop objects that depend on the foreign-data wrapper (such as foreign tables and servers), and in turn all objects that depend on those objects (see [Section 5.14](#)).

RESTRICT

Refuse to drop the foreign-data wrapper if any objects depend on it. This is the default.

## Examples

Drop the foreign-data wrapper `dbi`:

```
DROP FOREIGN DATA WRAPPER dbi;
```

## Compatibility

DROP FOREIGN DATA WRAPPER conforms to ISO/IEC 9075-9 (SQL/MED). The IF EXISTS clause is a Postgres Pro extension.

## See Also

[CREATE FOREIGN DATA WRAPPER](#), [ALTER FOREIGN DATA WRAPPER](#)

---

# DROP FOREIGN TABLE

DROP FOREIGN TABLE — remove a foreign table

## Synopsis

```
DROP FOREIGN TABLE [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]
```

## Description

DROP FOREIGN TABLE removes a foreign table. Only the owner of a foreign table can remove it.

## Parameters

IF EXISTS

Do not throw an error if the foreign table does not exist. A notice is issued in this case.

*name*

The name (optionally schema-qualified) of the foreign table to drop.

CASCADE

Automatically drop objects that depend on the foreign table (such as views), and in turn all objects that depend on those objects (see [Section 5.14](#)).

RESTRICT

Refuse to drop the foreign table if any objects depend on it. This is the default.

## Examples

To destroy two foreign tables, `films` and `distributors`:

```
DROP FOREIGN TABLE films, distributors;
```

## Compatibility

This command conforms to ISO/IEC 9075-9 (SQL/MED), except that the standard only allows one foreign table to be dropped per command, and apart from the `IF EXISTS` option, which is a Postgres Pro extension.

## See Also

[ALTER FOREIGN TABLE](#), [CREATE FOREIGN TABLE](#)

---

# DROP FUNCTION

DROP FUNCTION — remove a function

## Synopsis

```
DROP FUNCTION [ IF EXISTS ] name [ ( [ argmode ] [ argname ] argtype [, ...] ) ]  
[ , ... ]  
[ CASCADE | RESTRICT ]
```

## Description

DROP FUNCTION removes the definition of an existing function. To execute this command the user must be the owner of the function. The argument types to the function must be specified, since several different functions can exist with the same name and different argument lists.

## Parameters

IF EXISTS

Do not throw an error if the function does not exist. A notice is issued in this case.

*name*

The name (optionally schema-qualified) of an existing function. If no argument list is specified, the name must be unique in its schema.

*argmode*

The mode of an argument: IN, OUT, INOUT, or VARIADIC. If omitted, the default is IN. Note that DROP FUNCTION does not actually pay any attention to OUT arguments, since only the input arguments are needed to determine the function's identity. So it is sufficient to list the IN, INOUT, and VARIADIC arguments.

*argname*

The name of an argument. Note that DROP FUNCTION does not actually pay any attention to argument names, since only the argument data types are needed to determine the function's identity.

*argtype*

The data type(s) of the function's arguments (optionally schema-qualified), if any.

CASCADE

Automatically drop objects that depend on the function (such as operators or triggers), and in turn all objects that depend on those objects (see [Section 5.14](#)).

RESTRICT

Refuse to drop the function if any objects depend on it. This is the default.

## Examples

This command removes the square root function:

```
DROP FUNCTION sqrt(integer);
```

Drop multiple functions in one command:

```
DROP FUNCTION sqrt(integer), sqrt(bigint);
```

If the function name is unique in its schema, it can be referred to without an argument list:

```
DROP FUNCTION update_employee_salaries;
```

Note that this is different from

```
DROP FUNCTION update_employee_salaries();
```

which refers to a function with zero arguments, whereas the first variant can refer to a function with any number of arguments, including zero, as long as the name is unique.

### Compatibility

This command conforms to the SQL standard, with these Postgres Pro extensions:

- The standard only allows one function to be dropped per command.
- The `IF EXISTS` option
- The ability to specify argument modes and names

### See Also

[CREATE FUNCTION](#), [ALTER FUNCTION](#), [DROP PROCEDURE](#), [DROP ROUTINE](#)

---

# DROP GROUP

DROP GROUP — remove a database role

## Synopsis

```
DROP GROUP [ IF EXISTS ] name [, ...]
```

## Description

DROP GROUP is now an alias for [DROP ROLE](#).

## Compatibility

There is no DROP GROUP statement in the SQL standard.

## See Also

[DROP ROLE](#)

---

# DROP INDEX

DROP INDEX — remove an index

## Synopsis

```
DROP INDEX [ CONCURRENTLY ] [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]
```

## Description

DROP INDEX drops an existing index from the database system. To execute this command you must be the owner of the index.

## Parameters

CONCURRENTLY

Drop the index without locking out concurrent selects, inserts, updates, and deletes on the index's table. A normal DROP INDEX acquires an ACCESS EXCLUSIVE lock on the table, blocking other accesses until the index drop can be completed. With this option, the command instead waits until conflicting transactions have completed.

There are several caveats to be aware of when using this option. Only one index name can be specified, and the CASCADE option is not supported. (Thus, an index that supports a UNIQUE or PRIMARY KEY constraint cannot be dropped this way.) Also, regular DROP INDEX commands can be performed within a transaction block, but DROP INDEX CONCURRENTLY cannot. Lastly, indexes on partitioned tables cannot be dropped using this option.

For temporary tables, DROP INDEX is always non-concurrent, as no other session can access them, and non-concurrent index drop is cheaper.

IF EXISTS

Do not throw an error if the index does not exist. A notice is issued in this case.

*name*

The name (optionally schema-qualified) of an index to remove.

CASCADE

Automatically drop objects that depend on the index, and in turn all objects that depend on those objects (see [Section 5.14](#)).

RESTRICT

Refuse to drop the index if any objects depend on it. This is the default.

## Examples

This command will remove the index `title_idx`:

```
DROP INDEX title_idx;
```

## Compatibility

DROP INDEX is a Postgres Pro language extension. There are no provisions for indexes in the SQL standard.

## See Also

[CREATE INDEX](#)

---

# DROP LANGUAGE

DROP LANGUAGE — remove a procedural language

## Synopsis

```
DROP [ PROCEDURAL ] LANGUAGE [ IF EXISTS ] name [ CASCADE | RESTRICT ]
```

## Description

DROP LANGUAGE removes the definition of a previously registered procedural language. You must be a superuser or the owner of the language to use DROP LANGUAGE.

### Note

As of PostgreSQL 9.1, most procedural languages have been made into “extensions”, and should therefore be removed with [DROP EXTENSION](#) not DROP LANGUAGE.

## Parameters

IF EXISTS

Do not throw an error if the language does not exist. A notice is issued in this case.

*name*

The name of an existing procedural language. For backward compatibility, the name can be enclosed by single quotes.

CASCADE

Automatically drop objects that depend on the language (such as functions in the language), and in turn all objects that depend on those objects (see [Section 5.14](#)).

RESTRICT

Refuse to drop the language if any objects depend on it. This is the default.

## Examples

This command removes the procedural language `plsample`:

```
DROP LANGUAGE plsample;
```

## Compatibility

There is no DROP LANGUAGE statement in the SQL standard.

## See Also

[ALTER LANGUAGE](#), [CREATE LANGUAGE](#)

---

# DROP MATERIALIZED VIEW

DROP MATERIALIZED VIEW — remove a materialized view

## Synopsis

```
DROP MATERIALIZED VIEW [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]
```

## Description

DROP MATERIALIZED VIEW drops an existing materialized view. To execute this command you must be the owner of the materialized view.

## Parameters

IF EXISTS

Do not throw an error if the materialized view does not exist. A notice is issued in this case.

*name*

The name (optionally schema-qualified) of the materialized view to remove.

CASCADE

Automatically drop objects that depend on the materialized view (such as other materialized views, or regular views), and in turn all objects that depend on those objects (see [Section 5.14](#)).

RESTRICT

Refuse to drop the materialized view if any objects depend on it. This is the default.

## Examples

This command will remove the materialized view called `order_summary`:

```
DROP MATERIALIZED VIEW order_summary;
```

## Compatibility

DROP MATERIALIZED VIEW is a Postgres Pro extension.

## See Also

[CREATE MATERIALIZED VIEW](#), [ALTER MATERIALIZED VIEW](#), [REFRESH MATERIALIZED VIEW](#)

---

# DROP OPERATOR

DROP OPERATOR — remove an operator

## Synopsis

```
DROP OPERATOR [ IF EXISTS ] name ( { left_type | NONE } , { right_type | NONE } )  
[ , ... ] [ CASCADE | RESTRICT ]
```

## Description

DROP OPERATOR drops an existing operator from the database system. To execute this command you must be the owner of the operator.

## Parameters

IF EXISTS

Do not throw an error if the operator does not exist. A notice is issued in this case.

*name*

The name (optionally schema-qualified) of an existing operator.

*left\_type*

The data type of the operator's left operand; write NONE if the operator has no left operand.

*right\_type*

The data type of the operator's right operand; write NONE if the operator has no right operand.

CASCADE

Automatically drop objects that depend on the operator (such as views using it), and in turn all objects that depend on those objects (see [Section 5.14](#)).

RESTRICT

Refuse to drop the operator if any objects depend on it. This is the default.

## Examples

Remove the power operator  $a^b$  for type integer:

```
DROP OPERATOR ^ (integer, integer);
```

Remove the left unary bitwise complement operator  $\sim b$  for type bit:

```
DROP OPERATOR ~ (none, bit);
```

Remove the right unary factorial operator  $x!$  for type bigint:

```
DROP OPERATOR ! (bigint, none);
```

Remove multiple operators in one command:

```
DROP OPERATOR ~ (none, bit), ! (bigint, none);
```

## Compatibility

There is no DROP OPERATOR statement in the SQL standard.

**See Also**

[CREATE OPERATOR](#), [ALTER OPERATOR](#)

---

# DROP OPERATOR CLASS

DROP OPERATOR CLASS — remove an operator class

## Synopsis

```
DROP OPERATOR CLASS [ IF EXISTS ] name USING index_method [ CASCADE | RESTRICT ]
```

## Description

DROP OPERATOR CLASS drops an existing operator class. To execute this command you must be the owner of the operator class.

DROP OPERATOR CLASS does not drop any of the operators or functions referenced by the class. If there are any indexes depending on the operator class, you will need to specify CASCADE for the drop to complete.

## Parameters

IF EXISTS

Do not throw an error if the operator class does not exist. A notice is issued in this case.

*name*

The name (optionally schema-qualified) of an existing operator class.

*index\_method*

The name of the index access method the operator class is for.

CASCADE

Automatically drop objects that depend on the operator class (such as indexes), and in turn all objects that depend on those objects (see [Section 5.14](#)).

RESTRICT

Refuse to drop the operator class if any objects depend on it. This is the default.

## Notes

DROP OPERATOR CLASS will not drop the operator family containing the class, even if there is nothing else left in the family (in particular, in the case where the family was implicitly created by CREATE OPERATOR CLASS). An empty operator family is harmless, but for the sake of tidiness you might wish to remove the family with DROP OPERATOR FAMILY; or perhaps better, use DROP OPERATOR FAMILY in the first place.

## Examples

Remove the B-tree operator class `widget_ops`:

```
DROP OPERATOR CLASS widget_ops USING btree;
```

This command will not succeed if there are any existing indexes that use the operator class. Add CASCADE to drop such indexes along with the operator class.

## Compatibility

There is no DROP OPERATOR CLASS statement in the SQL standard.

## See Also

[ALTER OPERATOR CLASS](#), [CREATE OPERATOR CLASS](#), [DROP OPERATOR FAMILY](#)

---

# DROP OPERATOR FAMILY

DROP OPERATOR FAMILY — remove an operator family

## Synopsis

```
DROP OPERATOR FAMILY [ IF EXISTS ] name USING index_method [ CASCADE | RESTRICT ]
```

## Description

DROP OPERATOR FAMILY drops an existing operator family. To execute this command you must be the owner of the operator family.

DROP OPERATOR FAMILY includes dropping any operator classes contained in the family, but it does not drop any of the operators or functions referenced by the family. If there are any indexes depending on operator classes within the family, you will need to specify CASCADE for the drop to complete.

## Parameters

IF EXISTS

Do not throw an error if the operator family does not exist. A notice is issued in this case.

*name*

The name (optionally schema-qualified) of an existing operator family.

*index\_method*

The name of the index access method the operator family is for.

CASCADE

Automatically drop objects that depend on the operator family, and in turn all objects that depend on those objects (see [Section 5.14](#)).

RESTRICT

Refuse to drop the operator family if any objects depend on it. This is the default.

## Examples

Remove the B-tree operator family `float_ops`:

```
DROP OPERATOR FAMILY float_ops USING btree;
```

This command will not succeed if there are any existing indexes that use operator classes within the family. Add CASCADE to drop such indexes along with the operator family.

## Compatibility

There is no DROP OPERATOR FAMILY statement in the SQL standard.

## See Also

[ALTER OPERATOR FAMILY](#), [CREATE OPERATOR FAMILY](#), [ALTER OPERATOR CLASS](#), [CREATE OPERATOR CLASS](#), [DROP OPERATOR CLASS](#)

---

# DROP OWNED

DROP OWNED — remove database objects owned by a database role

## Synopsis

```
DROP OWNED BY { name | CURRENT_USER | SESSION_USER } [, ...] [ CASCADE | RESTRICT ]
```

## Description

DROP OWNED drops all the objects within the current database that are owned by one of the specified roles. Any privileges granted to the given roles on objects in the current database or on shared objects (databases, tablespaces) will also be revoked.

## Parameters

*name*

The name of a role whose objects will be dropped, and whose privileges will be revoked.

CASCADE

Automatically drop objects that depend on the affected objects, and in turn all objects that depend on those objects (see [Section 5.14](#)).

RESTRICT

Refuse to drop the objects owned by a role if any other database objects depend on one of the affected objects. This is the default.

## Notes

DROP OWNED is often used to prepare for the removal of one or more roles. Because DROP OWNED only affects the objects in the current database, it is usually necessary to execute this command in each database that contains objects owned by a role that is to be removed.

Using the CASCADE option might make the command recurse to objects owned by other users.

The REASSIGN OWNED command is an alternative that reassigns the ownership of all the database objects owned by one or more roles. However, REASSIGN OWNED does not deal with privileges for other objects.

Databases and tablespaces owned by the role(s) will not be removed.

See [Section 20.4](#) for more discussion.

## Compatibility

The DROP OWNED command is a Postgres Pro extension.

## See Also

[REASSIGN OWNED](#), [DROP ROLE](#)

---

# DROP POLICY

DROP POLICY — remove a row level security policy from a table

## Synopsis

```
DROP POLICY [ IF EXISTS ] name ON table_name [ CASCADE | RESTRICT ]
```

## Description

DROP POLICY removes the specified policy from the table. Note that if the last policy is removed for a table and the table still has row level security enabled via ALTER TABLE, then the default-deny policy will be used. ALTER TABLE ... DISABLE ROW LEVEL SECURITY can be used to disable row level security for a table, whether policies for the table exist or not.

## Parameters

IF EXISTS

Do not throw an error if the policy does not exist. A notice is issued in this case.

*name*

The name of the policy to drop.

*table\_name*

The name (optionally schema-qualified) of the table that the policy is on.

CASCADE

RESTRICT

These key words do not have any effect, since there are no dependencies on policies.

## Examples

To drop the policy called p1 on the table named my\_table:

```
DROP POLICY p1 ON my_table;
```

## Compatibility

DROP POLICY is a Postgres Pro extension.

## See Also

[CREATE POLICY](#), [ALTER POLICY](#)

---

# DROP PROCEDURE

DROP PROCEDURE — remove a procedure

## Synopsis

```
DROP PROCEDURE [ IF EXISTS ] name [ ( [ [ argmode ] [ argname ] argtype [, ...] ] ) ]
[ , ... ]
[ CASCADE | RESTRICT ]
```

## Description

`DROP PROCEDURE` removes the definition of an existing procedure. To execute this command the user must be the owner of the procedure. The argument types to the procedure must be specified, since several different procedures can exist with the same name and different argument lists.

## Parameters

`IF EXISTS`

Do not throw an error if the procedure does not exist. A notice is issued in this case.

*name*

The name (optionally schema-qualified) of an existing procedure. If no argument list is specified, the name must be unique in its schema.

*argmode*

The mode of an argument: `IN` or `VARIADIC`. If omitted, the default is `IN`.

*argname*

The name of an argument. Note that `DROP PROCEDURE` does not actually pay any attention to argument names, since only the argument data types are needed to determine the procedure's identity.

*argtype*

The data type(s) of the procedure's arguments (optionally schema-qualified), if any.

`CASCADE`

Automatically drop objects that depend on the procedure, and in turn all objects that depend on those objects (see [Section 5.14](#)).

`RESTRICT`

Refuse to drop the procedure if any objects depend on it. This is the default.

## Examples

```
DROP PROCEDURE do_db_maintenance();
```

## Compatibility

This command conforms to the SQL standard, with these Postgres Pro extensions:

- The standard only allows one procedure to be dropped per command.
- The `IF EXISTS` option
- The ability to specify argument modes and names

**See Also**

[CREATE PROCEDURE](#), [ALTER PROCEDURE](#), [DROP FUNCTION](#), [DROP ROUTINE](#)

---

# DROP PUBLICATION

DROP PUBLICATION — remove a publication

## Synopsis

```
DROP PUBLICATION [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]
```

## Description

DROP PUBLICATION removes an existing publication from the database.

A publication can only be dropped by its owner or a superuser.

## Parameters

IF EXISTS

Do not throw an error if the publication does not exist. A notice is issued in this case.

*name*

The name of an existing publication.

CASCADE

RESTRICT

These key words do not have any effect, since there are no dependencies on publications.

## Examples

Drop a publication:

```
DROP PUBLICATION mypublication;
```

## Compatibility

DROP PUBLICATION is a Postgres Pro extension.

## See Also

[CREATE PUBLICATION](#), [ALTER PUBLICATION](#)

---

# DROP ROLE

DROP ROLE — remove a database role

## Synopsis

```
DROP ROLE [ IF EXISTS ] name [, ...]
```

## Description

DROP ROLE removes the specified role(s). To drop a superuser role, you must be a superuser yourself; to drop non-superuser roles, you must have `CREATEROLE` privilege.

A role cannot be removed if it is still referenced in any database of the cluster; an error will be raised if so. Before dropping the role, you must drop all the objects it owns (or reassign their ownership) and revoke any privileges the role has been granted on other objects. The [REASSIGN OWNED](#) and [DROP OWNED](#) commands can be useful for this purpose; see [Section 20.4](#) for more discussion.

However, it is not necessary to remove role memberships involving the role; DROP ROLE automatically revokes any memberships of the target role in other roles, and of other roles in the target role. The other roles are not dropped nor otherwise affected.

## Parameters

IF EXISTS

Do not throw an error if the role does not exist. A notice is issued in this case.

*name*

The name of the role to remove.

## Notes

Postgres Pro includes a program [dropuser](#) that has the same functionality as this command (in fact, it calls this command) but can be run from the command shell.

## Examples

To drop a role:

```
DROP ROLE jonathan;
```

## Compatibility

The SQL standard defines DROP ROLE, but it allows only one role to be dropped at a time, and it specifies different privilege requirements than Postgres Pro uses.

## See Also

[CREATE ROLE](#), [ALTER ROLE](#), [SET ROLE](#)

---

# DROP ROUTINE

DROP ROUTINE — remove a routine

## Synopsis

```
DROP ROUTINE [ IF EXISTS ] name [ ( [ [ argmode ] [ argname ] argtype [, ...] ] ) ]  
[ , ... ]  
[ CASCADE | RESTRICT ]
```

## Description

DROP ROUTINE removes the definition of an existing routine, which can be an aggregate function, a normal function, or a procedure. See under [DROP AGGREGATE](#), [DROP FUNCTION](#), and [DROP PROCEDURE](#) for the description of the parameters, more examples, and further details.

## Examples

To drop the routine `foo` for type `integer`:

```
DROP ROUTINE foo(integer);
```

This command will work independent of whether `foo` is an aggregate, function, or procedure.

## Compatibility

This command conforms to the SQL standard, with these Postgres Pro extensions:

- The standard only allows one routine to be dropped per command.
- The `IF EXISTS` option
- The ability to specify argument modes and names
- Aggregate functions are an extension.

## See Also

[DROP AGGREGATE](#), [DROP FUNCTION](#), [DROP PROCEDURE](#), [ALTER ROUTINE](#)

Note that there is no `CREATE ROUTINE` command.

---

# DROP RULE

DROP RULE — remove a rewrite rule

## Synopsis

```
DROP RULE [ IF EXISTS ] name ON table_name [ CASCADE | RESTRICT ]
```

## Description

DROP RULE drops a rewrite rule.

## Parameters

IF EXISTS

Do not throw an error if the rule does not exist. A notice is issued in this case.

*name*

The name of the rule to drop.

*table\_name*

The name (optionally schema-qualified) of the table or view that the rule applies to.

CASCADE

Automatically drop objects that depend on the rule, and in turn all objects that depend on those objects (see [Section 5.14](#)).

RESTRICT

Refuse to drop the rule if any objects depend on it. This is the default.

## Examples

To drop the rewrite rule `newrule`:

```
DROP RULE newrule ON mytable;
```

## Compatibility

DROP RULE is a Postgres Pro language extension, as is the entire query rewrite system.

## See Also

[CREATE RULE](#), [ALTER RULE](#)

---

# DROP SCHEMA

DROP SCHEMA — remove a schema

## Synopsis

```
DROP SCHEMA [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]
```

## Description

DROP SCHEMA removes schemas from the database.

A schema can only be dropped by its owner or a superuser. Note that the owner can drop the schema (and thereby all contained objects) even if they do not own some of the objects within the schema.

## Parameters

IF EXISTS

Do not throw an error if the schema does not exist. A notice is issued in this case.

*name*

The name of a schema.

CASCADE

Automatically drop objects (tables, functions, etc.) that are contained in the schema, and in turn all objects that depend on those objects (see [Section 5.14](#)).

RESTRICT

Refuse to drop the schema if it contains any objects. This is the default.

## Notes

Using the CASCADE option might make the command remove objects in other schemas besides the one(s) named.

## Examples

To remove schema `mystuff` from the database, along with everything it contains:

```
DROP SCHEMA mystuff CASCADE;
```

## Compatibility

DROP SCHEMA is fully conforming with the SQL standard, except that the standard only allows one schema to be dropped per command, and apart from the IF EXISTS option, which is a Postgres Pro extension.

## See Also

[ALTER SCHEMA](#), [CREATE SCHEMA](#)

---

# DROP SEQUENCE

DROP SEQUENCE — remove a sequence

## Synopsis

```
DROP SEQUENCE [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]
```

## Description

DROP SEQUENCE removes sequence number generators. A sequence can only be dropped by its owner or a superuser.

## Parameters

IF EXISTS

Do not throw an error if the sequence does not exist. A notice is issued in this case.

*name*

The name (optionally schema-qualified) of a sequence.

CASCADE

Automatically drop objects that depend on the sequence, and in turn all objects that depend on those objects (see [Section 5.14](#)).

RESTRICT

Refuse to drop the sequence if any objects depend on it. This is the default.

## Examples

To remove the sequence `serial`:

```
DROP SEQUENCE serial;
```

## Compatibility

DROP SEQUENCE conforms to the SQL standard, except that the standard only allows one sequence to be dropped per command, and apart from the IF EXISTS option, which is a Postgres Pro extension.

## See Also

[CREATE SEQUENCE](#), [ALTER SEQUENCE](#)

---

# DROP SERVER

DROP SERVER — remove a foreign server descriptor

## Synopsis

```
DROP SERVER [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]
```

## Description

DROP SERVER removes an existing foreign server descriptor. To execute this command, the current user must be the owner of the server.

## Parameters

IF EXISTS

Do not throw an error if the server does not exist. A notice is issued in this case.

*name*

The name of an existing server.

CASCADE

Automatically drop objects that depend on the server (such as user mappings), and in turn all objects that depend on those objects (see [Section 5.14](#)).

RESTRICT

Refuse to drop the server if any objects depend on it. This is the default.

## Examples

Drop a server `foo` if it exists:

```
DROP SERVER IF EXISTS foo;
```

## Compatibility

DROP SERVER conforms to ISO/IEC 9075-9 (SQL/MED). The IF EXISTS clause is a Postgres Pro extension.

## See Also

[CREATE SERVER](#), [ALTER SERVER](#)

---

# DROP STATISTICS

DROP STATISTICS — remove extended statistics

## Synopsis

```
DROP STATISTICS [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]
```

## Description

DROP STATISTICS removes statistics object(s) from the database. Only the statistics object's owner, the schema owner, or a superuser can drop a statistics object.

## Parameters

IF EXISTS

Do not throw an error if the statistics object does not exist. A notice is issued in this case.

*name*

The name (optionally schema-qualified) of the statistics object to drop.

CASCADE

RESTRICT

These key words do not have any effect, since there are no dependencies on statistics.

## Examples

To destroy two statistics objects in different schemas, without failing if they don't exist:

```
DROP STATISTICS IF EXISTS
  accounting.users_uid_creation,
  public.grants_user_role;
```

## Compatibility

There is no DROP STATISTICS command in the SQL standard.

## See Also

[ALTER STATISTICS](#), [CREATE STATISTICS](#)

---

# DROP SUBSCRIPTION

DROP SUBSCRIPTION — remove a subscription

## Synopsis

```
DROP SUBSCRIPTION [ IF EXISTS ] name [ CASCADE | RESTRICT ]
```

## Description

DROP SUBSCRIPTION removes a subscription from the database cluster.

A subscription can only be dropped by a superuser.

DROP SUBSCRIPTION cannot be executed inside a transaction block if the subscription is associated with a replication slot. (You can use ALTER SUBSCRIPTION to unset the slot.)

## Parameters

*name*

The name of a subscription to be dropped.

CASCADE  
RESTRICT

These key words do not have any effect, since there are no dependencies on subscriptions.

## Notes

When dropping a subscription that is associated with a replication slot on the remote host (the normal state), DROP SUBSCRIPTION will connect to the remote host and try to drop the replication slot as part of its operation. This is necessary so that the resources allocated for the subscription on the remote host are released. If this fails, either because the remote host is not reachable or because the remote replication slot cannot be dropped or does not exist or never existed, the DROP SUBSCRIPTION command will fail. To proceed in this situation, disassociate the subscription from the replication slot by executing ALTER SUBSCRIPTION ... SET (slot\_name = NONE). After that, DROP SUBSCRIPTION will no longer attempt any actions on a remote host. Note that if the remote replication slot still exists, it should then be dropped manually; otherwise it will continue to reserve WAL and might eventually cause the disk to fill up. See also [Section 29.2.1](#).

If a subscription is associated with a replication slot, then DROP SUBSCRIPTION cannot be executed inside a transaction block.

## Examples

Drop a subscription:

```
DROP SUBSCRIPTION mysub;
```

## Compatibility

DROP SUBSCRIPTION is a Postgres Pro extension.

## See Also

[CREATE SUBSCRIPTION](#), [ALTER SUBSCRIPTION](#)

---

# DROP TABLE

DROP TABLE — remove a table

## Synopsis

```
DROP TABLE [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]
```

## Description

DROP TABLE removes tables from the database. Only the table owner, the schema owner, and superuser can drop a table. To empty a table of rows without destroying the table, use [DELETE](#) or [TRUNCATE](#).

DROP TABLE always removes any indexes, rules, triggers, and constraints that exist for the target table. However, to drop a table that is referenced by a view or a foreign-key constraint of another table, CASCADE must be specified. (CASCADE will remove a dependent view entirely, but in the foreign-key case it will only remove the foreign-key constraint, not the other table entirely.)

## Parameters

IF EXISTS

Do not throw an error if the table does not exist. A notice is issued in this case.

*name*

The name (optionally schema-qualified) of the table to drop.

CASCADE

Automatically drop objects that depend on the table (such as views), and in turn all objects that depend on those objects (see [Section 5.14](#)).

RESTRICT

Refuse to drop the table if any objects depend on it. This is the default.

## Examples

To destroy two tables, *films* and *distributors*:

```
DROP TABLE films, distributors;
```

## Compatibility

This command conforms to the SQL standard, except that the standard only allows one table to be dropped per command, and apart from the IF EXISTS option, which is a Postgres Pro extension.

## See Also

[ALTER TABLE](#), [CREATE TABLE](#)

---

# DROP TABLESPACE

DROP TABLESPACE — remove a tablespace

## Synopsis

```
DROP TABLESPACE [ IF EXISTS ] name
```

## Description

DROP TABLESPACE removes a tablespace from the system.

A tablespace can only be dropped by its owner or a superuser. The tablespace must be empty of all database objects before it can be dropped. It is possible that objects in other databases might still reside in the tablespace even if no objects in the current database are using the tablespace. Also, if the tablespace is listed in the [temp\\_tablespaces](#) setting of any active session, the DROP might fail due to temporary files residing in the tablespace.

## Parameters

IF EXISTS

Do not throw an error if the tablespace does not exist. A notice is issued in this case.

*name*

The name of a tablespace.

## Notes

DROP TABLESPACE cannot be executed inside a transaction block.

## Examples

To remove tablespace `mystuff` from the system:

```
DROP TABLESPACE mystuff;
```

## Compatibility

DROP TABLESPACE is a Postgres Pro extension.

## See Also

[CREATE TABLESPACE](#), [ALTER TABLESPACE](#)

---

# DROP TEXT SEARCH CONFIGURATION

DROP TEXT SEARCH CONFIGURATION — remove a text search configuration

## Synopsis

```
DROP TEXT SEARCH CONFIGURATION [ IF EXISTS ] name [ CASCADE | RESTRICT ]
```

## Description

DROP TEXT SEARCH CONFIGURATION drops an existing text search configuration. To execute this command you must be the owner of the configuration.

## Parameters

IF EXISTS

Do not throw an error if the text search configuration does not exist. A notice is issued in this case.

*name*

The name (optionally schema-qualified) of an existing text search configuration.

CASCADE

Automatically drop objects that depend on the text search configuration, and in turn all objects that depend on those objects (see [Section 5.14](#)).

RESTRICT

Refuse to drop the text search configuration if any objects depend on it. This is the default.

## Examples

Remove the text search configuration `my_english`:

```
DROP TEXT SEARCH CONFIGURATION my_english;
```

This command will not succeed if there are any existing indexes that reference the configuration in `to_tsvector` calls. Add `CASCADE` to drop such indexes along with the text search configuration.

## Compatibility

There is no DROP TEXT SEARCH CONFIGURATION statement in the SQL standard.

## See Also

[ALTER TEXT SEARCH CONFIGURATION](#), [CREATE TEXT SEARCH CONFIGURATION](#)

---

# DROP TEXT SEARCH DICTIONARY

DROP TEXT SEARCH DICTIONARY — remove a text search dictionary

## Synopsis

```
DROP TEXT SEARCH DICTIONARY [ IF EXISTS ] name [ CASCADE | RESTRICT ]
```

## Description

DROP TEXT SEARCH DICTIONARY drops an existing text search dictionary. To execute this command you must be the owner of the dictionary.

## Parameters

IF EXISTS

Do not throw an error if the text search dictionary does not exist. A notice is issued in this case.

*name*

The name (optionally schema-qualified) of an existing text search dictionary.

CASCADE

Automatically drop objects that depend on the text search dictionary, and in turn all objects that depend on those objects (see [Section 5.14](#)).

RESTRICT

Refuse to drop the text search dictionary if any objects depend on it. This is the default.

## Examples

Remove the text search dictionary `english`:

```
DROP TEXT SEARCH DICTIONARY english;
```

This command will not succeed if there are any existing text search configurations that use the dictionary. Add `CASCADE` to drop such configurations along with the dictionary.

## Compatibility

There is no `DROP TEXT SEARCH DICTIONARY` statement in the SQL standard.

## See Also

[ALTER TEXT SEARCH DICTIONARY](#), [CREATE TEXT SEARCH DICTIONARY](#)

---

# DROP TEXT SEARCH PARSER

DROP TEXT SEARCH PARSER — remove a text search parser

## Synopsis

```
DROP TEXT SEARCH PARSER [ IF EXISTS ] name [ CASCADE | RESTRICT ]
```

## Description

DROP TEXT SEARCH PARSER drops an existing text search parser. You must be a superuser to use this command.

## Parameters

IF EXISTS

Do not throw an error if the text search parser does not exist. A notice is issued in this case.

*name*

The name (optionally schema-qualified) of an existing text search parser.

CASCADE

Automatically drop objects that depend on the text search parser, and in turn all objects that depend on those objects (see [Section 5.14](#)).

RESTRICT

Refuse to drop the text search parser if any objects depend on it. This is the default.

## Examples

Remove the text search parser `my_parser`:

```
DROP TEXT SEARCH PARSER my_parser;
```

This command will not succeed if there are any existing text search configurations that use the parser. Add `CASCADE` to drop such configurations along with the parser.

## Compatibility

There is no `DROP TEXT SEARCH PARSER` statement in the SQL standard.

## See Also

[ALTER TEXT SEARCH PARSER](#), [CREATE TEXT SEARCH PARSER](#)

---

# DROP TEXT SEARCH TEMPLATE

DROP TEXT SEARCH TEMPLATE — remove a text search template

## Synopsis

```
DROP TEXT SEARCH TEMPLATE [ IF EXISTS ] name [ CASCADE | RESTRICT ]
```

## Description

DROP TEXT SEARCH TEMPLATE drops an existing text search template. You must be a superuser to use this command.

## Parameters

IF EXISTS

Do not throw an error if the text search template does not exist. A notice is issued in this case.

*name*

The name (optionally schema-qualified) of an existing text search template.

CASCADE

Automatically drop objects that depend on the text search template, and in turn all objects that depend on those objects (see [Section 5.14](#)).

RESTRICT

Refuse to drop the text search template if any objects depend on it. This is the default.

## Examples

Remove the text search template `thesaurus`:

```
DROP TEXT SEARCH TEMPLATE thesaurus;
```

This command will not succeed if there are any existing text search dictionaries that use the template. Add `CASCADE` to drop such dictionaries along with the template.

## Compatibility

There is no `DROP TEXT SEARCH TEMPLATE` statement in the SQL standard.

## See Also

[ALTER TEXT SEARCH TEMPLATE](#), [CREATE TEXT SEARCH TEMPLATE](#)

---

# DROP TRANSFORM

DROP TRANSFORM — remove a transform

## Synopsis

```
DROP TRANSFORM [ IF EXISTS ] FOR type_name LANGUAGE lang_name [ CASCADE | RESTRICT ]
```

## Description

DROP TRANSFORM removes a previously defined transform.

To be able to drop a transform, you must own the type and the language. These are the same privileges that are required to create a transform.

## Parameters

IF EXISTS

Do not throw an error if the transform does not exist. A notice is issued in this case.

*type\_name*

The name of the data type of the transform.

*lang\_name*

The name of the language of the transform.

CASCADE

Automatically drop objects that depend on the transform, and in turn all objects that depend on those objects (see [Section 5.14](#)).

RESTRICT

Refuse to drop the transform if any objects depend on it. This is the default.

## Examples

To drop the transform for type `hstore` and language `plpythonu`:

```
DROP TRANSFORM FOR hstore LANGUAGE plpythonu;
```

## Compatibility

This form of DROP TRANSFORM is a Postgres Pro extension. See [CREATE TRANSFORM](#) for details.

## See Also

[CREATE TRANSFORM](#)

---

# DROP TRIGGER

DROP TRIGGER — remove a trigger

## Synopsis

```
DROP TRIGGER [ IF EXISTS ] name ON table_name [ CASCADE | RESTRICT ]
```

## Description

DROP TRIGGER removes an existing trigger definition. To execute this command, the current user must be the owner of the table for which the trigger is defined.

## Parameters

IF EXISTS

Do not throw an error if the trigger does not exist. A notice is issued in this case.

*name*

The name of the trigger to remove.

*table\_name*

The name (optionally schema-qualified) of the table for which the trigger is defined.

CASCADE

Automatically drop objects that depend on the trigger, and in turn all objects that depend on those objects (see [Section 5.14](#)).

RESTRICT

Refuse to drop the trigger if any objects depend on it. This is the default.

## Examples

Destroy the trigger `if_dist_exists` on the table `films`:

```
DROP TRIGGER if_dist_exists ON films;
```

## Compatibility

The DROP TRIGGER statement in Postgres Pro is incompatible with the SQL standard. In the SQL standard, trigger names are not local to tables, so the command is simply DROP TRIGGER *name*.

## See Also

[CREATE TRIGGER](#)

---

# DROP TYPE

DROP TYPE — remove a data type

## Synopsis

```
DROP TYPE [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]
```

## Description

DROP TYPE removes a user-defined data type. Only the owner of a type can remove it.

## Parameters

IF EXISTS

Do not throw an error if the type does not exist. A notice is issued in this case.

*name*

The name (optionally schema-qualified) of the data type to remove.

CASCADE

Automatically drop objects that depend on the type (such as table columns, functions, and operators), and in turn all objects that depend on those objects (see [Section 5.14](#)).

RESTRICT

Refuse to drop the type if any objects depend on it. This is the default.

## Examples

To remove the data type `box`:

```
DROP TYPE box;
```

## Compatibility

This command is similar to the corresponding command in the SQL standard, apart from the `IF EXISTS` option, which is a Postgres Pro extension. But note that much of the `CREATE TYPE` command and the data type extension mechanisms in Postgres Pro differ from the SQL standard.

## See Also

[ALTER TYPE](#), [CREATE TYPE](#)

---

# DROP USER

DROP USER — remove a database role

## Synopsis

```
DROP USER [ IF EXISTS ] name [, ...]
```

## Description

DROP USER is simply an alternate spelling of [DROP ROLE](#).

## Compatibility

The DROP USER statement is a Postgres Pro extension. The SQL standard leaves the definition of users to the implementation.

## See Also

[DROP ROLE](#)

---

# DROP USER MAPPING

DROP USER MAPPING — remove a user mapping for a foreign server

## Synopsis

```
DROP USER MAPPING [ IF EXISTS ] FOR { user_name | USER | CURRENT_USER | PUBLIC }  
SERVER server_name
```

## Description

DROP USER MAPPING removes an existing user mapping from foreign server.

The owner of a foreign server can drop user mappings for that server for any user. Also, a user can drop a user mapping for their own user name if USAGE privilege on the server has been granted to the user.

## Parameters

IF EXISTS

Do not throw an error if the user mapping does not exist. A notice is issued in this case.

*user\_name*

User name of the mapping. CURRENT\_USER and USER match the name of the current user. PUBLIC is used to match all present and future user names in the system.

*server\_name*

Server name of the user mapping.

## Examples

Drop a user mapping bob, server foo if it exists:

```
DROP USER MAPPING IF EXISTS FOR bob SERVER foo;
```

## Compatibility

DROP USER MAPPING conforms to ISO/IEC 9075-9 (SQL/MED). The IF EXISTS clause is a Postgres Pro extension.

## See Also

[CREATE USER MAPPING](#), [ALTER USER MAPPING](#)

---

# DROP VIEW

DROP VIEW — remove a view

## Synopsis

```
DROP VIEW [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]
```

## Description

DROP VIEW drops an existing view. To execute this command you must be the owner of the view.

## Parameters

IF EXISTS

Do not throw an error if the view does not exist. A notice is issued in this case.

*name*

The name (optionally schema-qualified) of the view to remove.

CASCADE

Automatically drop objects that depend on the view (such as other views), and in turn all objects that depend on those objects (see [Section 5.14](#)).

RESTRICT

Refuse to drop the view if any objects depend on it. This is the default.

## Examples

This command will remove the view called `kinds`:

```
DROP VIEW kinds;
```

## Compatibility

This command conforms to the SQL standard, except that the standard only allows one view to be dropped per command, and apart from the `IF EXISTS` option, which is a Postgres Pro extension.

## See Also

[ALTER VIEW](#), [CREATE VIEW](#)

---

# END

END — commit the current transaction

## Synopsis

```
END [ WORK | TRANSACTION ] [ AND [ NO ] CHAIN ]
```

## Description

END commits the current transaction. All changes made by the transaction become visible to others and are guaranteed to be durable if a crash occurs. This command is a Postgres Pro extension that is equivalent to [COMMIT](#).

## Parameters

WORK  
TRANSACTION

Optional key words. They have no effect.

AND CHAIN

If `AND CHAIN` is specified, a new transaction is immediately started with the same transaction characteristics (see [SET TRANSACTION](#)) as the just finished one. Otherwise, no new transaction is started.

## Notes

Use [ROLLBACK](#) to abort a transaction.

Issuing `END` when not inside a transaction does no harm, but it will provoke a warning message.

## Examples

To commit the current transaction and make all changes permanent:

```
END;
```

## Compatibility

END is a Postgres Pro extension that provides functionality equivalent to [COMMIT](#), which is specified in the SQL standard.

## See Also

[BEGIN](#), [COMMIT](#), [ROLLBACK](#)

---

# EXECUTE

EXECUTE — execute a prepared statement

## Synopsis

```
EXECUTE name [ ( parameter [, ...] ) ]
```

## Description

EXECUTE is used to execute a previously prepared statement. Since prepared statements only exist for the duration of a session, the prepared statement must have been created by a PREPARE statement executed earlier in the current session.

If the PREPARE statement that created the statement specified some parameters, a compatible set of parameters must be passed to the EXECUTE statement, or else an error is raised. Note that (unlike functions) prepared statements are not overloaded based on the type or number of their parameters; the name of a prepared statement must be unique within a database session.

For more information on the creation and usage of prepared statements, see [PREPARE](#).

## Parameters

*name*

The name of the prepared statement to execute.

*parameter*

The actual value of a parameter to the prepared statement. This must be an expression yielding a value that is compatible with the data type of this parameter, as was determined when the prepared statement was created.

## Outputs

The command tag returned by EXECUTE is that of the prepared statement, and not EXECUTE.

## Examples

Examples are given in [Examples](#) in the [PREPARE](#) documentation.

## Compatibility

The SQL standard includes an EXECUTE statement, but it is only for use in embedded SQL. This version of the EXECUTE statement also uses a somewhat different syntax.

## See Also

[DEALLOCATE](#), [PREPARE](#)

---

# EXPLAIN

EXPLAIN — show the execution plan of a statement

## Synopsis

```
EXPLAIN [ ( option [, ...] ) ] statement
EXPLAIN [ ANALYZE ] [ VERBOSE ] statement
```

where *option* can be one of:

```
ANALYZE [ boolean ]
VERBOSE [ boolean ]
COSTS [ boolean ]
SETTINGS [ boolean ]
BUFFERS [ boolean ]
WAL [ boolean ]
TIMING [ boolean ]
SUMMARY [ boolean ]
FORMAT { TEXT | XML | JSON | YAML }
```

## Description

This command displays the execution plan that the Postgres Pro planner generates for the supplied statement. The execution plan shows how the table(s) referenced by the statement will be scanned — by plain sequential scan, index scan, etc. — and if multiple tables are referenced, what join algorithms will be used to bring together the required rows from each input table.

The most critical part of the display is the estimated statement execution cost, which is the planner's guess at how long it will take to run the statement (measured in cost units that are arbitrary, but conventionally mean disk page fetches). Actually two numbers are shown: the start-up cost before the first row can be returned, and the total cost to return all the rows. For most queries the total cost is what matters, but in contexts such as a subquery in `EXISTS`, the planner will choose the smallest start-up cost instead of the smallest total cost (since the executor will stop after getting one row, anyway). Also, if you limit the number of rows to return with a `LIMIT` clause, the planner makes an appropriate interpolation between the endpoint costs to estimate which plan is really the cheapest.

The `ANALYZE` option causes the statement to be actually executed, not only planned. Then actual run time statistics are added to the display, including the total elapsed time expended within each plan node (in milliseconds) and the total number of rows it actually returned. This is useful for seeing whether the planner's estimates are close to reality.

### Important

Keep in mind that the statement is actually executed when the `ANALYZE` option is used. Although `EXPLAIN` will discard any output that a `SELECT` would return, other side effects of the statement will happen as usual. If you wish to use `EXPLAIN ANALYZE` on an `INSERT`, `UPDATE`, `DELETE`, `CREATE TABLE AS`, or `EXECUTE` statement without letting the command affect your data, use this approach:

```
BEGIN;
EXPLAIN ANALYZE ...;
ROLLBACK;
```

Only the `ANALYZE` and `VERBOSE` options can be specified, and only in that order, without surrounding the option list in parentheses. Prior to PostgreSQL 9.0, the unparenthesized syntax was the only one supported. It is expected that all new options will be supported only in the parenthesized syntax.

## Parameters

### ANALYZE

Carry out the command and show actual run times and other statistics. This parameter defaults to `FALSE`.

### VERBOSE

Display additional information regarding the plan. Specifically, include the output column list for each node in the plan tree, schema-qualify table and function names, always label variables in expressions with their range table alias, and always print the name of each trigger for which statistics are displayed. This parameter defaults to `FALSE`.

### COSTS

Include information on the estimated startup and total cost of each plan node, as well as the estimated number of rows and the estimated width of each row. This parameter defaults to `TRUE`.

### SETTINGS

Include information on configuration parameters. Specifically, include options affecting query planning with value different from the built-in default value. This parameter defaults to `FALSE`.

### BUFFERS

Include information on buffer usage. Specifically, include the number of shared blocks hit, read, dirtied, and written, the number of local blocks hit, read, dirtied, and written, the number of temp blocks read and written, and the time spent reading and writing data file blocks (in milliseconds) if [track\\_io\\_timing](#) is enabled. A *hit* means that a read was avoided because the block was found already in cache when needed. Shared blocks contain data from regular tables and indexes; local blocks contain data from temporary tables and indexes; while temp blocks contain short-term working data used in sorts, hashes, Materialize plan nodes, and similar cases. The number of blocks *dirtied* indicates the number of previously unmodified blocks that were changed by this query; while the number of blocks *written* indicates the number of previously-dirtied blocks evicted from cache by this backend during query processing. The number of blocks shown for an upper-level node includes those used by all its child nodes. In text format, only non-zero values are printed. It defaults to `FALSE`.

### WAL

Include information on WAL record generation. Specifically, include the number of records, number of full page images (fpi) and the amount of WAL generated in bytes. In text format, only non-zero values are printed. This parameter may only be used when `ANALYZE` is also enabled. It defaults to `FALSE`.

### TIMING

Include actual startup time and time spent in each node in the output. The overhead of repeatedly reading the system clock can slow down the query significantly on some systems, so it may be useful to set this parameter to `FALSE` when only actual row counts, and not exact times, are needed. Run time of the entire statement is always measured, even when node-level timing is turned off with this option. This parameter may only be used when `ANALYZE` is also enabled. It defaults to `TRUE`.

### SUMMARY

Include summary information (e.g., totaled timing information) after the query plan. Summary information is included by default when `ANALYZE` is used but otherwise is not included by default, but can be enabled using this option. Planning time in `EXPLAIN EXECUTE` includes the time required to fetch the plan from the cache and the time required for re-planning, if necessary.

### FORMAT

Specify the output format, which can be `TEXT`, `XML`, `JSON`, or `YAML`. Non-text output contains the same information as the text output format, but is easier for programs to parse. This parameter defaults to `TEXT`.

*boolean*

Specifies whether the selected option should be turned on or off. You can write `TRUE`, `ON`, or `1` to enable the option, and `FALSE`, `OFF`, or `0` to disable it. The *boolean* value can also be omitted, in which case `TRUE` is assumed.

*statement*

Any `SELECT`, `INSERT`, `UPDATE`, `DELETE`, `VALUES`, `EXECUTE`, `DECLARE`, `CREATE TABLE AS`, or `CREATE MATERIALIZED VIEW AS statement`, whose execution plan you wish to see.

## Outputs

The command's result is a textual description of the plan selected for the *statement*, optionally annotated with execution statistics. [Section 14.1](#) describes the information provided.

## Notes

In order to allow the Postgres Pro query planner to make reasonably informed decisions when optimizing queries, the `pg_statistic` data should be up-to-date for all tables used in the query. Normally the [autovacuum daemon](#) will take care of that automatically. But if a table has recently had substantial changes in its contents, you might need to do a manual [ANALYZE](#) rather than wait for autovacuum to catch up with the changes.

In order to measure the run-time cost of each node in the execution plan, the current implementation of `EXPLAIN ANALYZE` adds profiling overhead to query execution. As a result, running `EXPLAIN ANALYZE` on a query can sometimes take significantly longer than executing the query normally. The amount of overhead depends on the nature of the query, as well as the platform being used. The worst case occurs for plan nodes that in themselves require very little time per execution, and on machines that have relatively slow operating system calls for obtaining the time of day.

## Examples

To show the plan for a simple query on a table with a single `integer` column and 10000 rows:

```
EXPLAIN SELECT * FROM foo;
```

```
QUERY PLAN
```

```
-----
Seq Scan on foo (cost=0.00..155.00 rows=10000 width=4)
(1 row)
```

Here is the same query, with JSON output formatting:

```
EXPLAIN (FORMAT JSON) SELECT * FROM foo;
```

```
QUERY PLAN
```

```
-----
[
  {
    "Plan": {
      "Node Type": "Seq Scan",
      "Relation Name": "foo",
      "Alias": "foo",
      "Startup Cost": 0.00,
      "Total Cost": 155.00,
      "Plan Rows": 10000,
      "Plan Width": 4
    }
  }
]
(1 row)
```

## EXPLAIN

---

If there is an index and we use a query with an indexable WHERE condition, EXPLAIN might show a different plan:

```
EXPLAIN SELECT * FROM foo WHERE i = 4;
```

### QUERY PLAN

```
-----
Index Scan using fi on foo (cost=0.00..5.98 rows=1 width=4)
  Index Cond: (i = 4)
(2 rows)
```

Here is the same query, but in YAML format:

```
EXPLAIN (FORMAT YAML) SELECT * FROM foo WHERE i='4';
QUERY PLAN
```

```
-----
- Plan: +
  Node Type: "Index Scan" +
  Scan Direction: "Forward"+
  Index Name: "fi" +
  Relation Name: "foo" +
  Alias: "foo" +
  Startup Cost: 0.00 +
  Total Cost: 5.98 +
  Plan Rows: 1 +
  Plan Width: 4 +
  Index Cond: "(i = 4)"
(1 row)
```

XML format is left as an exercise for the reader.

Here is the same plan with cost estimates suppressed:

```
EXPLAIN (COSTS FALSE) SELECT * FROM foo WHERE i = 4;
```

### QUERY PLAN

```
-----
Index Scan using fi on foo
  Index Cond: (i = 4)
(2 rows)
```

Here is an example of a query plan for a query using an aggregate function:

```
EXPLAIN SELECT sum(i) FROM foo WHERE i < 10;
```

### QUERY PLAN

```
-----
Aggregate (cost=23.93..23.93 rows=1 width=4)
-> Index Scan using fi on foo (cost=0.00..23.92 rows=6 width=4)
  Index Cond: (i < 10)
(3 rows)
```

Here is an example of using EXPLAIN EXECUTE to display the execution plan for a prepared query:

```
PREPARE query(int, int) AS SELECT sum(bar) FROM test
  WHERE id > $1 AND id < $2
  GROUP BY foo;
```

```
EXPLAIN ANALYZE EXECUTE query(100, 200);
```

QUERY PLAN

```
-----  
-----  
HashAggregate (cost=9.54..9.54 rows=1 width=8) (actual time=0.156..0.161 rows=11  
loops=1)  
  Group Key: foo  
    -> Index Scan using test_pkey on test (cost=0.29..9.29 rows=50 width=8) (actual  
time=0.039..0.091 rows=99 loops=1)  
      Index Cond: ((id > $1) AND (id < $2))  
Planning time: 0.197 ms  
Execution time: 0.225 ms  
(6 rows)
```

Of course, the specific numbers shown here depend on the actual contents of the tables involved. Also note that the numbers, and even the selected query strategy, might vary between Postgres Pro releases due to planner improvements. In addition, the `ANALYZE` command uses random sampling to estimate data statistics; therefore, it is possible for cost estimates to change after a fresh run of `ANALYZE`, even if the actual distribution of data in the table has not changed.

## Compatibility

There is no `EXPLAIN` statement defined in the SQL standard.

## See Also

[ANALYZE](#)

---

# FETCH

FETCH — retrieve rows from a query using a cursor

## Synopsis

```
FETCH [ direction [ FROM | IN ] ] cursor_name
```

where *direction* can be empty or one of:

```
NEXT  
PRIOR  
FIRST  
LAST  
ABSOLUTE count  
RELATIVE count  
count  
ALL  
FORWARD  
FORWARD count  
FORWARD ALL  
BACKWARD  
BACKWARD count  
BACKWARD ALL
```

## Description

FETCH retrieves rows using a previously-created cursor.

A cursor has an associated position, which is used by FETCH. The cursor position can be before the first row of the query result, on any particular row of the result, or after the last row of the result. When created, a cursor is positioned before the first row. After fetching some rows, the cursor is positioned on the row most recently retrieved. If FETCH runs off the end of the available rows then the cursor is left positioned after the last row, or before the first row if fetching backward. FETCH ALL or FETCH BACKWARD ALL will always leave the cursor positioned after the last row or before the first row.

The forms NEXT, PRIOR, FIRST, LAST, ABSOLUTE, RELATIVE fetch a single row after moving the cursor appropriately. If there is no such row, an empty result is returned, and the cursor is left positioned before the first row or after the last row as appropriate.

The forms using FORWARD and BACKWARD retrieve the indicated number of rows moving in the forward or backward direction, leaving the cursor positioned on the last-returned row (or after/before all rows, if the *count* exceeds the number of rows available).

RELATIVE 0, FORWARD 0, and BACKWARD 0 all request fetching the current row without moving the cursor, that is, re-fetching the most recently fetched row. This will succeed unless the cursor is positioned before the first row or after the last row; in which case, no row is returned.

### Note

This page describes usage of cursors at the SQL command level. If you are trying to use cursors inside a PL/pgSQL function, the rules are different — see [Section 40.7.3](#).

## Parameters

*direction*

*direction* defines the fetch direction and number of rows to fetch. It can be one of the following:

NEXT

Fetch the next row. This is the default if *direction* is omitted.

PRIOR

Fetch the prior row.

FIRST

Fetch the first row of the query (same as ABSOLUTE 1).

LAST

Fetch the last row of the query (same as ABSOLUTE -1).

ABSOLUTE *count*

Fetch the *count*'th row of the query, or the  $\text{abs}(\text{count})$ 'th row from the end if *count* is negative. Position before first row or after last row if *count* is out of range; in particular, ABSOLUTE 0 positions before the first row.

RELATIVE *count*

Fetch the *count*'th succeeding row, or the  $\text{abs}(\text{count})$ 'th prior row if *count* is negative. RELATIVE 0 re-fetches the current row, if any.

*count*

Fetch the next *count* rows (same as FORWARD *count*).

ALL

Fetch all remaining rows (same as FORWARD ALL).

FORWARD

Fetch the next row (same as NEXT).

FORWARD *count*

Fetch the next *count* rows. FORWARD 0 re-fetches the current row.

FORWARD ALL

Fetch all remaining rows.

BACKWARD

Fetch the prior row (same as PRIOR).

BACKWARD *count*

Fetch the prior *count* rows (scanning backwards). BACKWARD 0 re-fetches the current row.

BACKWARD ALL

Fetch all prior rows (scanning backwards).

*count*

*count* is a possibly-signed integer constant, determining the location or number of rows to fetch. For FORWARD and BACKWARD cases, specifying a negative *count* is equivalent to changing the sense of FORWARD and BACKWARD.

*cursor\_name*

An open cursor's name.

## Outputs

On successful completion, a `FETCH` command returns a command tag of the form

```
FETCH count
```

The `count` is the number of rows fetched (possibly zero). Note that in `psql`, the command tag will not actually be displayed, since `psql` displays the fetched rows instead.

## Notes

The cursor should be declared with the `SCROLL` option if one intends to use any variants of `FETCH` other than `FETCH NEXT` or `FETCH FORWARD` with a positive count. For simple queries Postgres Pro will allow backwards fetch from cursors not declared with `SCROLL`, but this behavior is best not relied on. If the cursor is declared with `NO SCROLL`, no backward fetches are allowed.

`ABSOLUTE` fetches are not any faster than navigating to the desired row with a relative move: the underlying implementation must traverse all the intermediate rows anyway. Negative absolute fetches are even worse: the query must be read to the end to find the last row, and then traversed backward from there. However, rewinding to the start of the query (as with `FETCH ABSOLUTE 0`) is fast.

`DECLARE` is used to define a cursor. Use `MOVE` to change cursor position without retrieving data.

## Examples

The following example traverses a table using a cursor:

```
BEGIN WORK;

-- Set up a cursor:
DECLARE liahona SCROLL CURSOR FOR SELECT * FROM films;

-- Fetch the first 5 rows in the cursor liahona:
FETCH FORWARD 5 FROM liahona;
```

code	title	did	date_prod	kind	len
BL101	The Third Man	101	1949-12-23	Drama	01:44
BL102	The African Queen	101	1951-08-11	Romantic	01:43
JL201	Une Femme est une Femme	102	1961-03-12	Romantic	01:25
P_301	Vertigo	103	1958-11-14	Action	02:08
P_302	Becket	103	1964-02-03	Drama	02:28

```

-- Fetch the previous row:
FETCH PRIOR FROM liahona;
```

code	title	did	date_prod	kind	len
P_301	Vertigo	103	1958-11-14	Action	02:08

```

-- Close the cursor and end the transaction:
CLOSE liahona;
COMMIT WORK;
```

## Compatibility

The SQL standard defines `FETCH` for use in embedded SQL only. The variant of `FETCH` described here returns the data as if it were a `SELECT` result rather than placing it in host variables. Other than this point, `FETCH` is fully upward-compatible with the SQL standard.

The `FETCH` forms involving `FORWARD` and `BACKWARD`, as well as the forms `FETCH count` and `FETCH ALL`, in which `FORWARD` is implicit, are Postgres Pro extensions.

The SQL standard allows only `FROM` preceding the cursor name; the option to use `IN`, or to leave them out altogether, is an extension.

# GRANT

GRANT — define access privileges

## Synopsis

```
GRANT { { SELECT | INSERT | UPDATE | DELETE | TRUNCATE | REFERENCES | TRIGGER }
        [, ...] | ALL [ PRIVILEGES ] }
ON { [ TABLE ] table_name [, ...]
     | ALL TABLES IN SCHEMA schema_name [, ...] }
TO role_specification [, ...] [ WITH GRANT OPTION ]

GRANT { { SELECT | INSERT | UPDATE | REFERENCES } ( column_name [, ...] )
        [, ...] | ALL [ PRIVILEGES ] ( column_name [, ...] ) }
ON [ TABLE ] table_name [, ...]
TO role_specification [, ...] [ WITH GRANT OPTION ]

GRANT { { USAGE | SELECT | UPDATE }
        [, ...] | ALL [ PRIVILEGES ] }
ON { SEQUENCE sequence_name [, ...]
     | ALL SEQUENCES IN SCHEMA schema_name [, ...] }
TO role_specification [, ...] [ WITH GRANT OPTION ]

GRANT { { CREATE | CONNECT | TEMPORARY | TEMP } [, ...] | ALL [ PRIVILEGES ] }
ON DATABASE database_name [, ...]
TO role_specification [, ...] [ WITH GRANT OPTION ]

GRANT { USAGE | ALL [ PRIVILEGES ] }
ON DOMAIN domain_name [, ...]
TO role_specification [, ...] [ WITH GRANT OPTION ]

GRANT { USAGE | ALL [ PRIVILEGES ] }
ON FOREIGN DATA WRAPPER fdw_name [, ...]
TO role_specification [, ...] [ WITH GRANT OPTION ]

GRANT { USAGE | ALL [ PRIVILEGES ] }
ON FOREIGN SERVER server_name [, ...]
TO role_specification [, ...] [ WITH GRANT OPTION ]

GRANT { EXECUTE | ALL [ PRIVILEGES ] }
ON { { FUNCTION | PROCEDURE | ROUTINE } routine_name [ ( [ [ argmode ] [ arg_name
] arg_type [, ...] ] ) ] [, ...]
     | ALL { FUNCTIONS | PROCEDURES | ROUTINES } IN SCHEMA schema_name [, ...] }
TO role_specification [, ...] [ WITH GRANT OPTION ]

GRANT { USAGE | ALL [ PRIVILEGES ] }
ON LANGUAGE lang_name [, ...]
TO role_specification [, ...] [ WITH GRANT OPTION ]

GRANT { { SELECT | UPDATE } [, ...] | ALL [ PRIVILEGES ] }
ON LARGE OBJECT loid [, ...]

  ON TYPE type_name [, ...]  
  TO role_specification [, ...] [ WITH GRANT OPTION ]
```

```
GRANT role_name [, ...] TO role_specification [, ...]  
  [ WITH ADMIN OPTION ]  
  [ GRANTED BY role_specification ]
```

where *role\_specification* can be:

```
[ GROUP ] role_name  
| PUBLIC  
| CURRENT_USER  
| SESSION_USER
```

## Description

The GRANT command has two basic variants: one that grants privileges on a database object (table, column, view, foreign table, sequence, database, foreign-data wrapper, foreign server, function, procedure, procedural language, schema, or tablespace), and one that grants membership in a role. These variants are similar in many ways, but they are different enough to be described separately.

### GRANT on Database Objects

This variant of the GRANT command gives specific privileges on a database object to one or more roles. These privileges are added to those already granted, if any.

The key word PUBLIC indicates that the privileges are to be granted to all roles, including those that might be created later. PUBLIC can be thought of as an implicitly defined group that always includes all roles. Any particular role will have the sum of privileges granted directly to it, privileges granted to any role it is presently a member of, and privileges granted to PUBLIC.

If WITH GRANT OPTION is specified, the recipient of the privilege can in turn grant it to others. Without a grant option, the recipient cannot do that. Grant options cannot be granted to PUBLIC.

There is no need to grant privileges to the owner of an object (usually the user that created it), as the owner has all privileges by default. (The owner could, however, choose to revoke some of their own privileges for safety.)

The right to drop an object, or to alter its definition in any way, is not treated as a grantable privilege; it is inherent in the owner, and cannot be granted or revoked. (However, a similar effect can be obtained by granting or revoking membership in the role that owns the object; see below.) The owner implicitly has all grant options for the object, too.

The possible privileges are:

SELECT  
INSERT  
UPDATE  
DELETE  
TRUNCATE  
REFERENCES  
TRIGGER  
CREATE  
CONNECT  
TEMPORARY  
EXECUTE  
USAGE

Specific types of privileges, as defined in [Section 5.7](#).

TEMP

Alternative spelling for TEMPORARY.

ALL PRIVILEGES

Grant all of the privileges available for the object's type. The PRIVILEGES key word is optional in Postgres Pro, though it is required by strict SQL.

The FUNCTION syntax works for plain functions, aggregate functions, and window functions, but not for procedures; use PROCEDURE for those. Alternatively, use ROUTINE to refer to a function, aggregate function, window function, or procedure regardless of its precise type.

There is also an option to grant privileges on all objects of the same type within one or more schemas. This functionality is currently supported only for tables, sequences, functions, and procedures. ALL TABLES also affects views and foreign tables, just like the specific-object GRANT command. ALL FUNCTIONS also affects aggregate and window functions, but not procedures, again just like the specific-object GRANT command. Use ALL ROUTINES to include procedures.

## GRANT on Roles

This variant of the GRANT command grants membership in a role to one or more other roles. Membership in a role is significant because it conveys the privileges granted to a role to each of its members.

If WITH ADMIN OPTION is specified, the member can in turn grant membership in the role to others, and revoke membership in the role as well. Without the admin option, ordinary users cannot do that. A role is not considered to hold WITH ADMIN OPTION on itself, but it may grant or revoke membership in itself from a database session where the session user matches the role. Database superusers can grant or revoke membership in any role to anyone. Roles having CREATEROLE privilege can grant or revoke membership in any role that is not a superuser.

If GRANTED BY is specified, the grant is recorded as having been done by the specified role. Only database superusers may use this option, except when it names the same role executing the command.

Unlike the case with privileges, membership in a role cannot be granted to PUBLIC. Note also that this form of the command does not allow the noise word GROUP in *role\_specification*.

## Notes

The REVOKE command is used to revoke access privileges.

Since PostgreSQL 8.1, the concepts of users and groups have been unified into a single kind of entity called a role. It is therefore no longer necessary to use the keyword GROUP to identify whether a grantee is a user or a group. GROUP is still allowed in the command, but it is a noise word.

A user may perform `SELECT`, `INSERT`, etc. on a column if they hold that privilege for either the specific column or its whole table. Granting the privilege at the table level and then revoking it for one column will not do what one might wish: the table-level grant is unaffected by a column-level operation.

When a non-owner of an object attempts to `GRANT` privileges on the object, the command will fail outright if the user has no privileges whatsoever on the object. As long as some privilege is available, the command will proceed, but it will grant only those privileges for which the user has grant options. The `GRANT ALL PRIVILEGES` forms will issue a warning message if no grant options are held, while the other forms will issue a warning if grant options for any of the privileges specifically named in the command are not held. (In principle these statements apply to the object owner as well, but since the owner is always treated as holding all grant options, the cases can never occur.)

It should be noted that database superusers can access all objects regardless of object privilege settings. This is comparable to the rights of `root` in a Unix system. As with `root`, it's unwise to operate as a superuser except when absolutely necessary.

If a superuser chooses to issue a `GRANT` or `REVOKE` command, the command is performed as though it were issued by the owner of the affected object. In particular, privileges granted via such a command will appear to have been granted by the object owner. (For role membership, the membership appears to have been granted by the containing role itself.)

`GRANT` and `REVOKE` can also be done by a role that is not the owner of the affected object, but is a member of the role that owns the object, or is a member of a role that holds privileges `WITH GRANT OPTION` on the object. In this case the privileges will be recorded as having been granted by the role that actually owns the object or holds the privileges `WITH GRANT OPTION`. For example, if table `t1` is owned by role `g1`, of which role `u1` is a member, then `u1` can grant privileges on `t1` to `u2`, but those privileges will appear to have been granted directly by `g1`. Any other member of role `g1` could revoke them later.

If the role executing `GRANT` holds the required privileges indirectly via more than one role membership path, it is unspecified which containing role will be recorded as having done the grant. In such cases it is best practice to use `SET ROLE` to become the specific role you want to do the `GRANT` as.

Granting permission on a table does not automatically extend permissions to any sequences used by the table, including sequences tied to `SERIAL` columns. Permissions on sequences must be set separately.

See [Section 5.7](#) for more information about specific privilege types, as well as how to inspect objects' privileges.

## Examples

Grant insert privilege to all users on table `films`:

```
GRANT INSERT ON films TO PUBLIC;
```

Grant all available privileges to user `manuel` on view `kinds`:

```
GRANT ALL PRIVILEGES ON kinds TO manuel;
```

Note that while the above will indeed grant all privileges if executed by a superuser or the owner of `kinds`, when executed by someone else it will only grant those permissions for which the someone else has grant options.

Grant membership in role `admins` to user `joe`:

```
GRANT admins TO joe;
```

## Compatibility

According to the SQL standard, the `PRIVILEGES` key word in `ALL PRIVILEGES` is required. The SQL standard does not support setting the privileges on more than one object per command.

Postgres Pro allows an object owner to revoke their own ordinary privileges: for example, a table owner can make the table read-only to themselves by revoking their own `INSERT`, `UPDATE`, `DELETE`, and `TRUNCATE`

privileges. This is not possible according to the SQL standard. The reason is that Postgres Pro treats the owner's privileges as having been granted by the owner to themselves; therefore they can revoke them too. In the SQL standard, the owner's privileges are granted by an assumed entity “\_SYSTEM”. Not being “\_SYSTEM”, the owner cannot revoke these rights.

According to the SQL standard, grant options can be granted to PUBLIC; Postgres Pro only supports granting grant options to roles.

The SQL standard allows the GRANTED BY option to be used in all forms of GRANT. Postgres Pro only supports it when granting role membership, and even then only superusers may use it in nontrivial ways.

The SQL standard provides for a USAGE privilege on other kinds of objects: character sets, collations, translations.

In the SQL standard, sequences only have a USAGE privilege, which controls the use of the NEXT VALUE FOR expression, which is equivalent to the function nextval in Postgres Pro. The sequence privileges SELECT and UPDATE are Postgres Pro extensions. The application of the sequence USAGE privilege to the currval function is also a Postgres Pro extension (as is the function itself).

Privileges on databases, tablespaces, schemas, and languages are Postgres Pro extensions.

# IMPORT FOREIGN SCHEMA

IMPORT FOREIGN SCHEMA — import table definitions from a foreign server

## Synopsis

```
IMPORT FOREIGN SCHEMA remote_schema
  [ { LIMIT TO | EXCEPT } ( table_name [, ...] ) ]
FROM SERVER server_name
INTO local_schema
  [ OPTIONS ( option 'value' [, ...] ) ]
```

## Description

IMPORT FOREIGN SCHEMA creates foreign tables that represent tables existing on a foreign server. The new foreign tables will be owned by the user issuing the command and are created with the correct column definitions and options to match the remote tables.

By default, all tables and views existing in a particular schema on the foreign server are imported. Optionally, the list of tables can be limited to a specified subset, or specific tables can be excluded. The new foreign tables are all created in the target schema, which must already exist.

To use IMPORT FOREIGN SCHEMA, the user must have USAGE privilege on the foreign server, as well as CREATE privilege on the target schema.

## Parameters

*remote\_schema*

The remote schema to import from. The specific meaning of a remote schema depends on the foreign data wrapper in use.

LIMIT TO ( *table\_name* [, ...] )

Import only foreign tables matching one of the given table names. Other tables existing in the foreign schema will be ignored.

EXCEPT ( *table\_name* [, ...] )

Exclude specified foreign tables from the import. All tables existing in the foreign schema will be imported except the ones listed here.

*server\_name*

The foreign server to import from.

*local\_schema*

The schema in which the imported foreign tables will be created.

OPTIONS ( *option* 'value' [, ...] )

Options to be used during the import. The allowed option names and values are specific to each foreign data wrapper.

## Examples

Import table definitions from a remote schema `foreign_films` on server `film_server`, creating the foreign tables in local schema `films`:

```
IMPORT FOREIGN SCHEMA foreign_films
  FROM SERVER film_server INTO films;
```

As above, but import only the two tables `actors` and `directors` (if they exist):

```
IMPORT FOREIGN SCHEMA foreign_films LIMIT TO (actors, directors)
FROM SERVER film_server INTO films;
```

### Compatibility

The `IMPORT FOREIGN SCHEMA` command conforms to the SQL standard, except that the `OPTIONS` clause is a Postgres Pro extension.

# INSERT

INSERT — create new rows in a table

## Synopsis

```
[ WITH [ RECURSIVE ] with_query [, ...] ]
INSERT INTO table_name [ AS alias ] [ ( column_name [, ...] ) ]
    [ OVERRIDING { SYSTEM | USER } VALUE ]
    { DEFAULT VALUES | VALUES ( { expression | DEFAULT } [, ...] ) [, ...] | query }
    [ ON CONFLICT [ conflict_target ] conflict_action ]
    [ RETURNING * | output_expression [ [ AS ] output_name ] [, ...] ]
```

where *conflict\_target* can be one of:

```
( { index_column_name | ( index_expression ) } [ COLLATE collation ] [ opclass ]
[, ...] ) [ WHERE index_predicate ]
ON CONSTRAINT constraint_name
```

and *conflict\_action* is one of:

```
DO NOTHING
DO UPDATE SET { column_name = { expression | DEFAULT } |
               ( column_name [, ...] ) = [ ROW ] ( { expression | DEFAULT }
[, ...] ) |
               ( column_name [, ...] ) = ( sub-SELECT )
               } [, ...]
[ WHERE condition ]
```

## Description

INSERT inserts new rows into a table. One can insert one or more rows specified by value expressions, or zero or more rows resulting from a query.

The target column names can be listed in any order. If no list of column names is given at all, the default is all the columns of the table in their declared order; or the first *N* column names, if there are only *N* columns supplied by the VALUES clause or *query*. The values supplied by the VALUES clause or *query* are associated with the explicit or implicit column list left-to-right.

Each column not present in the explicit or implicit column list will be filled with a default value, either its declared default value or null if there is none.

If the expression for any column is not of the correct data type, automatic type conversion will be attempted.

ON CONFLICT can be used to specify an alternative action to raising a unique constraint or exclusion constraint violation error. (See [ON CONFLICT Clause](#) below.)

The optional RETURNING clause causes INSERT to compute and return value(s) based on each row actually inserted (or updated, if an ON CONFLICT DO UPDATE clause was used). This is primarily useful for obtaining values that were supplied by defaults, such as a serial sequence number. However, any expression using the table's columns is allowed. The syntax of the RETURNING list is identical to that of the output list of SELECT. Only rows that were successfully inserted or updated will be returned. For example, if a row was locked but not updated because an ON CONFLICT DO UPDATE ... WHERE clause *condition* was not satisfied, the row will not be returned.

You must have INSERT privilege on a table in order to insert into it. If ON CONFLICT DO UPDATE is present, UPDATE privilege on the table is also required.

If a column list is specified, you only need `INSERT` privilege on the listed columns. Similarly, when `ON CONFLICT DO UPDATE` is specified, you only need `UPDATE` privilege on the column(s) that are listed to be updated. However, `ON CONFLICT DO UPDATE` also requires `SELECT` privilege on any column whose values are read in the `ON CONFLICT DO UPDATE` expressions or *condition*.

Use of the `RETURNING` clause requires `SELECT` privilege on all columns mentioned in `RETURNING`. If you use the *query* clause to insert rows from a query, you of course need to have `SELECT` privilege on any table or column used in the query.

## Parameters

### Inserting

This section covers parameters that may be used when only inserting new rows. Parameters *exclusively* used with the `ON CONFLICT` clause are described separately.

*with\_query*

The `WITH` clause allows you to specify one or more subqueries that can be referenced by name in the `INSERT` query. See [Section 7.8](#) and [SELECT](#) for details.

It is possible for the *query* (`SELECT` statement) to also contain a `WITH` clause. In such a case both sets of *with\_query* can be referenced within the *query*, but the second one takes precedence since it is more closely nested.

*table\_name*

The name (optionally schema-qualified) of an existing table.

*alias*

A substitute name for *table\_name*. When an alias is provided, it completely hides the actual name of the table. This is particularly useful when `ON CONFLICT DO UPDATE` targets a table named `excluded`, since that will otherwise be taken as the name of the special table representing rows proposed for insertion.

*column\_name*

The name of a column in the table named by *table\_name*. The column name can be qualified with a subfield name or array subscript, if needed. (Inserting into only some fields of a composite column leaves the other fields null.) When referencing a column with `ON CONFLICT DO UPDATE`, do not include the table's name in the specification of a target column. For example, `INSERT INTO table_name ... ON CONFLICT DO UPDATE SET table_name.col = 1` is invalid (this follows the general behavior for `UPDATE`).

OVERRIDING SYSTEM VALUE

If this clause is specified, then any values supplied for identity columns will override the default sequence-generated values.

For an identity column defined as `GENERATED ALWAYS`, it is an error to insert an explicit value (other than `DEFAULT`) without specifying either `OVERRIDING SYSTEM VALUE` or `OVERRIDING USER VALUE`. (For an identity column defined as `GENERATED BY DEFAULT`, `OVERRIDING SYSTEM VALUE` is the normal behavior and specifying it does nothing, but PostgreSQL allows it as an extension.)

OVERRIDING USER VALUE

If this clause is specified, then any values supplied for identity columns are ignored and the default sequence-generated values are applied.

This clause is useful for example when copying values between tables. Writing `INSERT INTO tb12 OVERRIDING USER VALUE SELECT * FROM tb11` will copy from `tb11` all columns that are not identity

columns in `tbl2` while values for the identity columns in `tbl2` will be generated by the sequences associated with `tbl2`.

#### DEFAULT VALUES

All columns will be filled with their default values, as if `DEFAULT` were explicitly specified for each column. (An `OVERRIDING` clause is not permitted in this form.)

#### *expression*

An expression or value to assign to the corresponding column.

#### DEFAULT

The corresponding column will be filled with its default value. An identity column will be filled with a new value generated by the associated sequence. For a generated column, specifying this is permitted but merely specifies the normal behavior of computing the column from its generation expression.

#### *query*

A query (`SELECT` statement) that supplies the rows to be inserted. Refer to the [SELECT](#) statement for a description of the syntax.

#### *output\_expression*

An expression to be computed and returned by the `INSERT` command after each row is inserted or updated. The expression can use any column names of the table named by `table_name`. Write `*` to return all columns of the inserted or updated row(s).

#### *output\_name*

A name to use for a returned column.

## ON CONFLICT **Clause**

The optional `ON CONFLICT` clause specifies an alternative action to raising a unique violation or exclusion constraint violation error. For each individual row proposed for insertion, either the insertion proceeds, or, if an *arbiter* constraint or index specified by `conflict_target` is violated, the alternative `conflict_action` is taken. `ON CONFLICT DO NOTHING` simply avoids inserting a row as its alternative action. `ON CONFLICT DO UPDATE` updates the existing row that conflicts with the row proposed for insertion as its alternative action.

`conflict_target` can perform *unique index inference*. When performing inference, it consists of one or more `index_column_name` columns and/or `index_expression` expressions, and an optional `index_predicate`. All `table_name` unique indexes that, without regard to order, contain exactly the `conflict_target`-specified columns/expressions are inferred (chosen) as arbiter indexes. If an `index_predicate` is specified, it must, as a further requirement for inference, satisfy arbiter indexes. Note that this means a non-partial unique index (a unique index without a predicate) will be inferred (and thus used by `ON CONFLICT`) if such an index satisfying every other criteria is available. If an attempt at inference is unsuccessful, an error is raised.

`ON CONFLICT DO UPDATE` guarantees an atomic `INSERT` or `UPDATE` outcome; provided there is no independent error, one of those two outcomes is guaranteed, even under high concurrency. This is also known as *UPSERT* — “UPDATE or INSERT”.

#### *conflict\_target*

Specifies which conflicts `ON CONFLICT` takes the alternative action on by choosing *arbiter indexes*. Either performs *unique index inference*, or names a constraint explicitly. For `ON CONFLICT DO NOTHING`, it is optional to specify a `conflict_target`; when omitted, conflicts with all usable constraints (and unique indexes) are handled. For `ON CONFLICT DO UPDATE`, a `conflict_target` must be provided.

*conflict\_action*

*conflict\_action* specifies an alternative `ON CONFLICT` action. It can be either `DO NOTHING`, or a `DO UPDATE` clause specifying the exact details of the `UPDATE` action to be performed in case of a conflict. The `SET` and `WHERE` clauses in `ON CONFLICT DO UPDATE` have access to the existing row using the table's name (or an alias), and to rows proposed for insertion using the special `excluded` table. `SELECT` privilege is required on any column in the target table where corresponding `excluded` columns are read.

Note that the effects of all per-row `BEFORE INSERT` triggers are reflected in `excluded` values, since those effects may have contributed to the row being excluded from insertion.

*index\_column\_name*

The name of a *table\_name* column. Used to infer arbiter indexes. Follows `CREATE INDEX` format. `SELECT` privilege on *index\_column\_name* is required.

*index\_expression*

Similar to *index\_column\_name*, but used to infer expressions on *table\_name* columns appearing within index definitions (not simple columns). Follows `CREATE INDEX` format. `SELECT` privilege on any column appearing within *index\_expression* is required.

*collation*

When specified, mandates that corresponding *index\_column\_name* or *index\_expression* use a particular collation in order to be matched during inference. Typically this is omitted, as collations usually do not affect whether or not a constraint violation occurs. Follows `CREATE INDEX` format.

*opclass*

When specified, mandates that corresponding *index\_column\_name* or *index\_expression* use particular operator class in order to be matched during inference. Typically this is omitted, as the *equality* semantics are often equivalent across a type's operator classes anyway, or because it's sufficient to trust that the defined unique indexes have the pertinent definition of equality. Follows `CREATE INDEX` format.

*index\_predicate*

Used to allow inference of partial unique indexes. Any indexes that satisfy the predicate (which need not actually be partial indexes) can be inferred. Follows `CREATE INDEX` format. `SELECT` privilege on any column appearing within *index\_predicate* is required.

*constraint\_name*

Explicitly specifies an arbiter *constraint* by name, rather than inferring a constraint or index.

*condition*

An expression that returns a value of type `boolean`. Only rows for which this expression returns `true` will be updated, although all rows will be locked when the `ON CONFLICT DO UPDATE` action is taken. Note that *condition* is evaluated last, after a conflict has been identified as a candidate to update.

Note that exclusion constraints are not supported as arbiters with `ON CONFLICT DO UPDATE`. In all cases, only `NOT DEFERRABLE` constraints and unique indexes are supported as arbiters.

`INSERT` with an `ON CONFLICT DO UPDATE` clause is a “deterministic” statement. This means that the command will not be allowed to affect any single existing row more than once; a cardinality violation error will be raised when this situation arises. Rows proposed for insertion should not duplicate each other in terms of attributes constrained by an arbiter index or constraint.

Note that it is currently not supported for the `ON CONFLICT DO UPDATE` clause of an `INSERT` applied to a partitioned table to update the partition key of a conflicting row such that it requires the row be moved to a new partition.

**Tip**

It is often preferable to use unique index inference rather than naming a constraint directly using `ON CONFLICT ON CONSTRAINT constraint_name`. Inference will continue to work correctly when the underlying index is replaced by another more or less equivalent index in an overlapping way, for example when using `CREATE UNIQUE INDEX ... CONCURRENTLY` before dropping the index being replaced.

**Outputs**

On successful completion, an `INSERT` command returns a command tag of the form

```
INSERT oid count
```

The *count* is the number of rows inserted or updated. *oid* is always 0 (it used to be the OID assigned to the inserted row if *count* was exactly one and the target table was declared `WITH OIDS` and 0 otherwise, but creating a table `WITH OIDS` is not supported anymore).

If the `INSERT` command contains a `RETURNING` clause, the result will be similar to that of a `SELECT` statement containing the columns and values defined in the `RETURNING` list, computed over the row(s) inserted or updated by the command.

**Notes**

If the specified table is a partitioned table, each row is routed to the appropriate partition and inserted into it. If the specified table is a partition, an error will occur if one of the input rows violates the partition constraint.

**Examples**

Insert a single row into table `films`:

```
INSERT INTO films VALUES
('UA502', 'Bananas', 105, '1971-07-13', 'Comedy', '82 minutes');
```

In this example, the `len` column is omitted and therefore it will have the default value:

```
INSERT INTO films (code, title, did, date_prod, kind)
VALUES ('T_601', 'Yojimbo', 106, '1961-06-16', 'Drama');
```

This example uses the `DEFAULT` clause for the date columns rather than specifying a value:

```
INSERT INTO films VALUES
('UA502', 'Bananas', 105, DEFAULT, 'Comedy', '82 minutes');
INSERT INTO films (code, title, did, date_prod, kind)
VALUES ('T_601', 'Yojimbo', 106, DEFAULT, 'Drama');
```

To insert a row consisting entirely of default values:

```
INSERT INTO films DEFAULT VALUES;
```

To insert multiple rows using the `multirow VALUES` syntax:

```
INSERT INTO films (code, title, did, date_prod, kind) VALUES
('B6717', 'Tampopo', 110, '1985-02-10', 'Comedy'),
('HG120', 'The Dinner Game', 140, DEFAULT, 'Comedy');
```

This example inserts some rows into table `films` from a table `tmp_films` with the same column layout as `films`:

```
INSERT INTO films SELECT * FROM tmp_films WHERE date_prod < '2004-05-07';
```

This example inserts into array columns:

```
-- Create an empty 3x3 gameboard for noughts-and-crosses
INSERT INTO tictactoe (game, board[1:3][1:3])
  VALUES (1, '{{" ", " ", " "},{ " ", " ", " "},{ " ", " ", " "}}');
-- The subscripts in the above example aren't really needed
INSERT INTO tictactoe (game, board)
  VALUES (2, '{{X, " ", " "},{ " ", O, " "},{ " ", X, " "}}');
```

Insert a single row into table distributors, returning the sequence number generated by the DEFAULT clause:

```
INSERT INTO distributors (did, dname) VALUES (DEFAULT, 'XYZ Widgets')
  RETURNING did;
```

Increment the sales count of the salesperson who manages the account for Acme Corporation, and record the whole updated row along with current time in a log table:

```
WITH upd AS (
  UPDATE employees SET sales_count = sales_count + 1 WHERE id =
    (SELECT sales_person FROM accounts WHERE name = 'Acme Corporation')
  RETURNING *
)
INSERT INTO employees_log SELECT *, current_timestamp FROM upd;
```

Insert or update new distributors as appropriate. Assumes a unique index has been defined that constrains values appearing in the did column. Note that the special excluded table is used to reference values originally proposed for insertion:

```
INSERT INTO distributors (did, dname)
  VALUES (5, 'Gizmo Transglobal'), (6, 'Associated Computing, Inc')
  ON CONFLICT (did) DO UPDATE SET dname = EXCLUDED.dname;
```

Insert a distributor, or do nothing for rows proposed for insertion when an existing, excluded row (a row with a matching constrained column or columns after before row insert triggers fire) exists. Example assumes a unique index has been defined that constrains values appearing in the did column:

```
INSERT INTO distributors (did, dname) VALUES (7, 'Redline GmbH')
  ON CONFLICT (did) DO NOTHING;
```

Insert or update new distributors as appropriate. Example assumes a unique index has been defined that constrains values appearing in the did column. WHERE clause is used to limit the rows actually updated (any existing row not updated will still be locked, though):

```
-- Don't update existing distributors based in a certain ZIP code
INSERT INTO distributors AS d (did, dname) VALUES (8, 'Anvil Distribution')
  ON CONFLICT (did) DO UPDATE
  SET dname = EXCLUDED.dname || ' (formerly ' || d.dname || ')'
  WHERE d.zipcode <> '21201';
```

```
-- Name a constraint directly in the statement (uses associated
-- index to arbitrate taking the DO NOTHING action)
INSERT INTO distributors (did, dname) VALUES (9, 'Antwerp Design')
  ON CONFLICT ON CONSTRAINT distributors_pkey DO NOTHING;
```

Insert new distributor if possible; otherwise DO NOTHING. Example assumes a unique index has been defined that constrains values appearing in the did column on a subset of rows where the is\_active Boolean column evaluates to true:

```
-- This statement could infer a partial unique index on "did"
-- with a predicate of "WHERE is_active", but it could also
-- just use a regular unique constraint on "did"
```

```
INSERT INTO distributors (did, dname) VALUES (10, 'Conrad International')
ON CONFLICT (did) WHERE is_active DO NOTHING;
```

### Compatibility

INSERT conforms to the SQL standard, except that the RETURNING clause is a Postgres Pro extension, as is the ability to use WITH with INSERT, and the ability to specify an alternative action with ON CONFLICT. Also, the case in which a column name list is omitted, but not all the columns are filled from the VALUES clause or *query*, is disallowed by the standard.

The SQL standard specifies that OVERRIDING SYSTEM VALUE can only be specified if an identity column that is generated always exists. Postgres Pro allows the clause in any case and ignores it if it is not applicable.

Possible limitations of the *query* clause are documented under [SELECT](#).

---

# LISTEN

LISTEN — listen for a notification

## Synopsis

```
LISTEN channel
```

## Description

LISTEN registers the current session as a listener on the notification channel named *channel*. If the current session is already registered as a listener for this notification channel, nothing is done.

Whenever the command NOTIFY *channel* is invoked, either by this session or another one connected to the same database, all the sessions currently listening on that notification channel are notified, and each will in turn notify its connected client application.

A session can be unregistered for a given notification channel with the UNLISTEN command. A session's listen registrations are automatically cleared when the session ends.

The method a client application must use to detect notification events depends on which Postgres Pro application programming interface it uses. With the libpq library, the application issues LISTEN as an ordinary SQL command, and then must periodically call the function PQnotifies to find out whether any notification events have been received. Other interfaces such as libpgtcl provide higher-level methods for handling notify events; indeed, with libpgtcl the application programmer should not even issue LISTEN or UNLISTEN directly. See the documentation for the interface you are using for more details.

## Parameters

*channel*

Name of a notification channel (any identifier).

## Notes

LISTEN takes effect at transaction commit. If LISTEN or UNLISTEN is executed within a transaction that later rolls back, the set of notification channels being listened to is unchanged.

A transaction that has executed LISTEN cannot be prepared for two-phase commit.

There is a race condition when first setting up a listening session: if concurrently-committing transactions are sending notify events, exactly which of those will the newly listening session receive? The answer is that the session will receive all events committed after an instant during the transaction's commit step. But that is slightly later than any database state that the transaction could have observed in queries. This leads to the following rule for using LISTEN: first execute (and commit!) that command, then in a new transaction inspect the database state as needed by the application logic, then rely on notifications to find out about subsequent changes to the database state. The first few received notifications might refer to updates already observed in the initial database inspection, but this is usually harmless.

[NOTIFY](#) contains a more extensive discussion of the use of LISTEN and NOTIFY.

## Examples

Configure and execute a listen/notify sequence from psql:

```
LISTEN virtual;  
NOTIFY virtual;  
Asynchronous notification "virtual" received from server process with PID 8448.
```

## Compatibility

There is no `LISTEN` statement in the SQL standard.

## See Also

[NOTIFY](#), [UNLISTEN](#)

---

# LOAD

LOAD — load a shared library file

## Synopsis

```
LOAD 'filename'
```

## Description

This command loads a shared library file into the Postgres Pro server's address space. If the file has been loaded already, the command does nothing. Shared library files that contain C functions are automatically loaded whenever one of their functions is called. Therefore, an explicit `LOAD` is usually only needed to load a library that modifies the server's behavior through “hooks” rather than providing a set of functions.

The library file name is typically given as just a bare file name, which is sought in the server's library search path (set by [dynamic\\_library\\_path](#)). Alternatively it can be given as a full path name. In either case the platform's standard shared library file name extension may be omitted. See [Section 35.10.1](#) for more information on this topic.

Non-superusers can only apply `LOAD` to library files located in `$libdir/plugins/` — the specified *filename* must begin with exactly that string. (It is the database administrator's responsibility to ensure that only “safe” libraries are installed there.)

## Compatibility

`LOAD` is a Postgres Pro extension.

## See Also

[CREATE FUNCTION](#)

---

# LOCK

LOCK — lock a table

## Synopsis

```
LOCK [ TABLE ] [ ONLY ] name [ * ] [, ...] [ IN lockmode MODE ] [ NOWAIT ]
```

where *lockmode* is one of:

```
ACCESS SHARE | ROW SHARE | ROW EXCLUSIVE | SHARE UPDATE EXCLUSIVE  
| SHARE | SHARE ROW EXCLUSIVE | EXCLUSIVE | ACCESS EXCLUSIVE
```

## Description

`LOCK TABLE` obtains a table-level lock, waiting if necessary for any conflicting locks to be released. If `NOWAIT` is specified, `LOCK TABLE` does not wait to acquire the desired lock: if it cannot be acquired immediately, the command is aborted and an error is emitted. Once obtained, the lock is held for the remainder of the current transaction. (There is no `UNLOCK TABLE` command; locks are always released at transaction end.)

When a view is locked, all relations appearing in the view definition query are also locked recursively with the same lock mode.

When acquiring locks automatically for commands that reference tables, Postgres Pro always uses the least restrictive lock mode possible. `LOCK TABLE` provides for cases when you might need more restrictive locking. For example, suppose an application runs a transaction at the `READ COMMITTED` isolation level and needs to ensure that data in a table remains stable for the duration of the transaction. To achieve this you could obtain `SHARE` lock mode over the table before querying. This will prevent concurrent data changes and ensure subsequent reads of the table see a stable view of committed data, because `SHARE` lock mode conflicts with the `ROW EXCLUSIVE` lock acquired by writers, and your `LOCK TABLE name IN SHARE MODE` statement will wait until any concurrent holders of `ROW EXCLUSIVE` mode locks commit or roll back. Thus, once you obtain the lock, there are no uncommitted writes outstanding; furthermore none can begin until you release the lock.

To achieve a similar effect when running a transaction at the `REPEATABLE READ` or `SERIALIZABLE` isolation level, you have to execute the `LOCK TABLE` statement before executing any `SELECT` or data modification statement. A `REPEATABLE READ` or `SERIALIZABLE` transaction's view of data will be frozen when its first `SELECT` or data modification statement begins. A `LOCK TABLE` later in the transaction will still prevent concurrent writes — but it won't ensure that what the transaction reads corresponds to the latest committed values.

If a transaction of this sort is going to change the data in the table, then it should use `SHARE ROW EXCLUSIVE` lock mode instead of `SHARE` mode. This ensures that only one transaction of this type runs at a time. Without this, a deadlock is possible: two transactions might both acquire `SHARE` mode, and then be unable to also acquire `ROW EXCLUSIVE` mode to actually perform their updates. (Note that a transaction's own locks never conflict, so a transaction can acquire `ROW EXCLUSIVE` mode when it holds `SHARE` mode — but not if anyone else holds `SHARE` mode.) To avoid deadlocks, make sure all transactions acquire locks on the same objects in the same order, and if multiple lock modes are involved for a single object, then transactions should always acquire the most restrictive mode first.

More information about the lock modes and locking strategies can be found in [Section 13.3](#).

## Parameters

*name*

The name (optionally schema-qualified) of an existing table to lock. If `ONLY` is specified before the table name, only that table is locked. If `ONLY` is not specified, the table and all its descendant tables

(if any) are locked. Optionally, `*` can be specified after the table name to explicitly indicate that descendant tables are included.

The command `LOCK TABLE a, b;` is equivalent to `LOCK TABLE a; LOCK TABLE b;`. The tables are locked one-by-one in the order specified in the `LOCK TABLE` command.

#### *lockmode*

The lock mode specifies which locks this lock conflicts with. Lock modes are described in [Section 13.3](#).

If no lock mode is specified, then `ACCESS EXCLUSIVE`, the most restrictive mode, is used.

#### `NOWAIT`

Specifies that `LOCK TABLE` should not wait for any conflicting locks to be released: if the specified lock(s) cannot be acquired immediately without waiting, the transaction is aborted.

## Notes

`LOCK TABLE ... IN ACCESS SHARE MODE` requires `SELECT` privileges on the target table. `LOCK TABLE ... IN ROW EXCLUSIVE MODE` requires `INSERT`, `UPDATE`, `DELETE`, or `TRUNCATE` privileges on the target table. All other forms of `LOCK` require table-level `UPDATE`, `DELETE`, or `TRUNCATE` privileges.

The user performing the lock on the view must have the corresponding privilege on the view. In addition the view's owner must have the relevant privileges on the underlying base relations, but the user performing the lock does not need any permissions on the underlying base relations.

`LOCK TABLE` is useless outside a transaction block: the lock would remain held only to the completion of the statement. Therefore Postgres Pro reports an error if `LOCK` is used outside a transaction block. Use [BEGIN](#) and [COMMIT](#) (or [ROLLBACK](#)) to define a transaction block.

`LOCK TABLE` only deals with table-level locks, and so the mode names involving `ROW` are all misnomers. These mode names should generally be read as indicating the intention of the user to acquire row-level locks within the locked table. Also, `ROW EXCLUSIVE` mode is a shareable table lock. Keep in mind that all the lock modes have identical semantics so far as `LOCK TABLE` is concerned, differing only in the rules about which modes conflict with which. For information on how to acquire an actual row-level lock, see [Section 13.3.2](#) and [The Locking Clause](#) in the [SELECT](#) documentation.

## Examples

Obtain a `SHARE` lock on a primary key table when going to perform inserts into a foreign key table:

```
BEGIN WORK;
LOCK TABLE films IN SHARE MODE;
SELECT id FROM films
  WHERE name = 'Star Wars: Episode I - The Phantom Menace';
-- Do ROLLBACK if record was not returned
INSERT INTO films_user_comments VALUES
  (_id_, 'GREAT! I was waiting for it for so long!');
COMMIT WORK;
```

Take a `SHARE ROW EXCLUSIVE` lock on a primary key table when going to perform a delete operation:

```
BEGIN WORK;
LOCK TABLE films IN SHARE ROW EXCLUSIVE MODE;
DELETE FROM films_user_comments WHERE id IN
  (SELECT id FROM films WHERE rating < 5);
DELETE FROM films WHERE rating < 5;
COMMIT WORK;
```

## Compatibility

There is no `LOCK TABLE` in the SQL standard, which instead uses `SET TRANSACTION` to specify concurrency levels on transactions. Postgres Pro supports that too; see [SET TRANSACTION](#) for details.

Except for `ACCESS SHARE`, `ACCESS EXCLUSIVE`, and `SHARE UPDATE EXCLUSIVE` lock modes, the Postgres Pro lock modes and the `LOCK TABLE` syntax are compatible with those present in Oracle.

---

# MOVE

MOVE — position a cursor

## Synopsis

```
MOVE [ direction [ FROM | IN ] ] cursor_name
```

where *direction* can be empty or one of:

```
NEXT
PRIOR
FIRST
LAST
ABSOLUTE count
RELATIVE count
count
ALL
FORWARD
FORWARD count
FORWARD ALL
BACKWARD
BACKWARD count
BACKWARD ALL
```

## Description

MOVE repositions a cursor without retrieving any data. MOVE works exactly like the FETCH command, except it only positions the cursor and does not return rows.

The parameters for the MOVE command are identical to those of the FETCH command; refer to [FETCH](#) for details on syntax and usage.

## Outputs

On successful completion, a MOVE command returns a command tag of the form

```
MOVE count
```

The *count* is the number of rows that a FETCH command with the same parameters would have returned (possibly zero).

## Examples

```
BEGIN WORK;
DECLARE liahona CURSOR FOR SELECT * FROM films;

-- Skip the first 5 rows:
MOVE FORWARD 5 IN liahona;
MOVE 5

-- Fetch the 6th row from the cursor liahona:
FETCH 1 FROM liahona;
  code | title | did | date_prod | kind | len
-----+-----+-----+-----+-----+-----
  P_303 | 48 Hrs | 103 | 1982-10-22 | Action | 01:37
(1 row)
```

```
-- Close the cursor liahona and end the transaction:  
CLOSE liahona;  
COMMIT WORK;
```

### **Compatibility**

There is no `MOVE` statement in the SQL standard.

### **See Also**

[CLOSE](#), [DECLARE](#), [FETCH](#)

---

# NOTIFY

NOTIFY — generate a notification

## Synopsis

```
NOTIFY channel [ , payload ]
```

## Description

The `NOTIFY` command sends a notification event together with an optional “payload” string to each client application that has previously executed `LISTEN channel` for the specified channel name in the current database. Notifications are visible to all users.

`NOTIFY` provides a simple interprocess communication mechanism for a collection of processes accessing the same Postgres Pro database. A payload string can be sent along with the notification, and higher-level mechanisms for passing structured data can be built by using tables in the database to pass additional data from notifier to listener(s).

The information passed to the client for a notification event includes the notification channel name, the notifying session's server process PID, and the payload string, which is an empty string if it has not been specified.

It is up to the database designer to define the channel names that will be used in a given database and what each one means. Commonly, the channel name is the same as the name of some table in the database, and the notify event essentially means, “I changed this table, take a look at it to see what's new”. But no such association is enforced by the `NOTIFY` and `LISTEN` commands. For example, a database designer could use several different channel names to signal different sorts of changes to a single table. Alternatively, the payload string could be used to differentiate various cases.

When `NOTIFY` is used to signal the occurrence of changes to a particular table, a useful programming technique is to put the `NOTIFY` in a statement trigger that is triggered by table updates. In this way, notification happens automatically when the table is changed, and the application programmer cannot accidentally forget to do it.

`NOTIFY` interacts with SQL transactions in some important ways. Firstly, if a `NOTIFY` is executed inside a transaction, the notify events are not delivered until and unless the transaction is committed. This is appropriate, since if the transaction is aborted, all the commands within it have had no effect, including `NOTIFY`. But it can be disconcerting if one is expecting the notification events to be delivered immediately. Secondly, if a listening session receives a notification signal while it is within a transaction, the notification event will not be delivered to its connected client until just after the transaction is completed (either committed or aborted). Again, the reasoning is that if a notification were delivered within a transaction that was later aborted, one would want the notification to be undone somehow — but the server cannot “take back” a notification once it has sent it to the client. So notification events are only delivered between transactions. The upshot of this is that applications using `NOTIFY` for real-time signaling should try to keep their transactions short.

If the same channel name is signaled multiple times with identical payload strings within the same transaction, only one instance of the notification event is delivered to listeners. On the other hand, notifications with distinct payload strings will always be delivered as distinct notifications. Similarly, notifications from different transactions will never get folded into one notification. Except for dropping later instances of duplicate notifications, `NOTIFY` guarantees that notifications from the same transaction get delivered in the order they were sent. It is also guaranteed that messages from different transactions are delivered in the order in which the transactions committed.

It is common for a client that executes `NOTIFY` to be listening on the same notification channel itself. In that case it will get back a notification event, just like all the other listening sessions. Depending on the application logic, this could result in useless work, for example, reading a database table to find the

same updates that that session just wrote out. It is possible to avoid such extra work by noticing whether the notifying session's server process PID (supplied in the notification event message) is the same as one's own session's PID (available from `libpq`). When they are the same, the notification event is one's own work bouncing back, and can be ignored.

## Parameters

*channel*

Name of the notification channel to be signaled (any identifier).

*payload*

The “payload” string to be communicated along with the notification. This must be specified as a simple string literal. In the default configuration it must be shorter than 8000 bytes. (If binary data or large amounts of information need to be communicated, it's best to put it in a database table and send the key of the record.)

## Notes

There is a queue that holds notifications that have been sent but not yet processed by all listening sessions. If this queue becomes full, transactions calling `NOTIFY` will fail at commit. The queue is quite large (8GB in a standard installation) and should be sufficiently sized for almost every use case. However, no cleanup can take place if a session executes `LISTEN` and then enters a transaction for a very long time. Once the queue is half full you will see warnings in the log file pointing you to the session that is preventing cleanup. In this case you should make sure that this session ends its current transaction so that cleanup can proceed.

The function `pg_notification_queue_usage` returns the fraction of the queue that is currently occupied by pending notifications. See [Section 9.26](#) for more information.

A transaction that has executed `NOTIFY` cannot be prepared for two-phase commit.

## pg\_notify

To send a notification you can also use the function `pg_notify(text, text)`. The function takes the channel name as the first argument and the payload as the second. The function is much easier to use than the `NOTIFY` command if you need to work with non-constant channel names and payloads.

## Examples

Configure and execute a listen/notify sequence from `psql`:

```
LISTEN virtual;
NOTIFY virtual;
Asynchronous notification "virtual" received from server process with PID 8448.
NOTIFY virtual, 'This is the payload';
Asynchronous notification "virtual" with payload "This is the payload" received from
server process with PID 8448.
```

```
LISTEN foo;
SELECT pg_notify('fo' || 'o', 'pay' || 'load');
Asynchronous notification "foo" with payload "payload" received from server process
with PID 14728.
```

## Compatibility

There is no `NOTIFY` statement in the SQL standard.

## See Also

[LISTEN](#), [UNLISTEN](#)

---

# PREPARE

PREPARE — prepare a statement for execution

## Synopsis

```
PREPARE name [ ( data_type [, ...] ) ] AS statement
```

## Description

PREPARE creates a prepared statement. A prepared statement is a server-side object that can be used to optimize performance. When the PREPARE statement is executed, the specified statement is parsed, analyzed, and rewritten. When an EXECUTE command is subsequently issued, the prepared statement is planned and executed. This division of labor avoids repetitive parse analysis work, while allowing the execution plan to depend on the specific parameter values supplied.

Prepared statements can take parameters: values that are substituted into the statement when it is executed. When creating the prepared statement, refer to parameters by position, using \$1, \$2, etc. A corresponding list of parameter data types can optionally be specified. When a parameter's data type is not specified or is declared as unknown, the type is inferred from the context in which the parameter is first referenced (if possible). When executing the statement, specify the actual values for these parameters in the EXECUTE statement. Refer to EXECUTE for more information about that.

Prepared statements only last for the duration of the current database session. When the session ends, the prepared statement is forgotten, so it must be recreated before being used again. This also means that a single prepared statement cannot be used by multiple simultaneous database clients; however, each client can create their own prepared statement to use. Prepared statements can be manually cleaned up using the DEALLOCATE command.

Prepared statements potentially have the largest performance advantage when a single session is being used to execute a large number of similar statements. The performance difference will be particularly significant if the statements are complex to plan or rewrite, e.g., if the query involves a join of many tables or requires the application of several rules. If the statement is relatively simple to plan and rewrite but relatively expensive to execute, the performance advantage of prepared statements will be less noticeable.

## Parameters

*name*

An arbitrary name given to this particular prepared statement. It must be unique within a single session and is subsequently used to execute or deallocate a previously prepared statement.

*data\_type*

The data type of a parameter to the prepared statement. If the data type of a particular parameter is unspecified or is specified as unknown, it will be inferred from the context in which the parameter is first referenced. To refer to the parameters in the prepared statement itself, use \$1, \$2, etc.

*statement*

Any SELECT, INSERT, UPDATE, DELETE, or VALUES statement.

## Notes

A prepared statement can be executed with either a *generic plan* or a *custom plan*. A generic plan is the same across all executions, while a custom plan is generated for a specific execution using the parameter values given in that call. Use of a generic plan avoids planning overhead, but in some situations a custom plan will be much more efficient to execute because the planner can make use of knowledge of the

parameter values. (Of course, if the prepared statement has no parameters, then this is moot and a generic plan is always used.)

By default (that is, when `plan_cache_mode` is set to `auto`), the server will automatically choose whether to use a generic or custom plan for a prepared statement that has parameters. The current rule for this is that the first five executions are done with custom plans and the average estimated cost of those plans is calculated. Then a generic plan is created and its estimated cost is compared to the average custom-plan cost. Subsequent executions use the generic plan if its cost is not so much higher than the average custom-plan cost as to make repeated replanning seem preferable.

This heuristic can be overridden, forcing the server to use either generic or custom plans, by setting `plan_cache_mode` to `force_generic_plan` or `force_custom_plan` respectively. This setting is primarily useful if the generic plan's cost estimate is badly off for some reason, allowing it to be chosen even though its actual cost is much more than that of a custom plan.

To examine the query plan Postgres Pro is using for a prepared statement, use [EXPLAIN](#), for example

```
EXPLAIN EXECUTE name(parameter_values);
```

If a generic plan is in use, it will contain parameter symbols `$n`, while a custom plan will have the supplied parameter values substituted into it.

For more information on query planning and the statistics collected by Postgres Pro for that purpose, see the [ANALYZE](#) documentation.

Although the main point of a prepared statement is to avoid repeated parse analysis and planning of the statement, Postgres Pro will force re-analysis and re-planning of the statement before using it whenever database objects used in the statement have undergone definitional (DDL) changes since the previous use of the prepared statement. Also, if the value of `search_path` changes from one use to the next, the statement will be re-parsed using the new `search_path`. (This latter behavior is new as of PostgreSQL 9.3.) These rules make use of a prepared statement semantically almost equivalent to re-submitting the same query text over and over, but with a performance benefit if no object definitions are changed, especially if the best plan remains the same across uses. An example of a case where the semantic equivalence is not perfect is that if the statement refers to a table by an unqualified name, and then a new table of the same name is created in a schema appearing earlier in the `search_path`, no automatic re-parse will occur since no object used in the statement changed. However, if some other change forces a re-parse, the new table will be referenced in subsequent uses.

You can see all prepared statements available in the session by querying the `pg_prepared_statements` system view.

## Examples

Create a prepared statement for an `INSERT` statement, and then execute it:

```
PREPARE fooplan (int, text, bool, numeric) AS
    INSERT INTO foo VALUES($1, $2, $3, $4);
EXECUTE fooplan(1, 'Hunter Valley', 't', 200.00);
```

Create a prepared statement for a `SELECT` statement, and then execute it:

```
PREPARE usrrptplan (int) AS
    SELECT * FROM users u, logs l WHERE u.usrid=$1 AND u.usrid=l.usrid
    AND l.date = $2;
EXECUTE usrrptplan(1, current_date);
```

In this example, the data type of the second parameter is not specified, so it is inferred from the context in which `$2` is used.

## Compatibility

The SQL standard includes a `PREPARE` statement, but it is only for use in embedded SQL. This version of the `PREPARE` statement also uses a somewhat different syntax.

**See Also**

[DEALLOCATE](#), [EXECUTE](#)

---

# PREPARE TRANSACTION

PREPARE TRANSACTION — prepare the current transaction for two-phase commit

## Synopsis

```
PREPARE TRANSACTION transaction_id
```

## Description

PREPARE TRANSACTION prepares the current transaction for two-phase commit. After this command, the transaction is no longer associated with the current session; instead, its state is fully stored on disk, and there is a very high probability that it can be committed successfully, even if a database crash occurs before the commit is requested.

Once prepared, a transaction can later be committed or rolled back with [COMMIT PREPARED](#) or [ROLLBACK PREPARED](#), respectively. Those commands can be issued from any session, not only the one that executed the original transaction.

From the point of view of the issuing session, PREPARE TRANSACTION is not unlike a ROLLBACK command: after executing it, there is no active current transaction, and the effects of the prepared transaction are no longer visible. (The effects will become visible again if the transaction is committed.)

If the PREPARE TRANSACTION command fails for any reason, it becomes a ROLLBACK: the current transaction is canceled.

## Parameters

*transaction\_id*

An arbitrary identifier that later identifies this transaction for [COMMIT PREPARED](#) or [ROLLBACK PREPARED](#). The identifier must be written as a string literal, and must be less than 200 bytes long. It must not be the same as the identifier used for any currently prepared transaction.

## Notes

PREPARE TRANSACTION is not intended for use in applications or interactive sessions. Its purpose is to allow an external transaction manager to perform atomic global transactions across multiple databases or other transactional resources. Unless you're writing a transaction manager, you probably shouldn't be using PREPARE TRANSACTION.

This command must be used inside a transaction block. Use [BEGIN](#) to start one.

It is not currently allowed to PREPARE a transaction that has executed any operations involving temporary tables or the session's temporary namespace, created any cursors WITH HOLD, or executed LISTEN, UNLISTEN, or NOTIFY. Those features are too tightly tied to the current session to be useful in a transaction to be prepared.

If the transaction modified any run-time parameters with SET (without the LOCAL option), those effects persist after PREPARE TRANSACTION, and will not be affected by any later COMMIT PREPARED or ROLLBACK PREPARED. Thus, in this one respect PREPARE TRANSACTION acts more like COMMIT than ROLLBACK.

All currently available prepared transactions are listed in the [pg\\_prepared\\_xacts](#) system view.

### Caution

It is unwise to leave transactions in the prepared state for a long time. This will interfere with the ability of VACUUM to reclaim storage, and in extreme cases could cause the database to shut down

to prevent transaction ID wraparound (see [Section 23.1.5](#)). Keep in mind also that the transaction continues to hold whatever locks it held. The intended usage of the feature is that a prepared transaction will normally be committed or rolled back as soon as an external transaction manager has verified that other databases are also prepared to commit.

If you have not set up an external transaction manager to track prepared transactions and ensure they get closed out promptly, it is best to keep the prepared-transaction feature disabled by setting [max\\_prepared\\_transactions](#) to zero. This will prevent accidental creation of prepared transactions that might then be forgotten and eventually cause problems.

## Examples

Prepare the current transaction for two-phase commit, using `foobar` as the transaction identifier:

```
PREPARE TRANSACTION 'foobar';
```

## Compatibility

`PREPARE TRANSACTION` is a Postgres Pro extension. It is intended for use by external transaction management systems, some of which are covered by standards (such as X/Open XA), but the SQL side of those systems is not standardized.

## See Also

[COMMIT PREPARED](#), [ROLLBACK PREPARED](#)

---

# REASSIGN OWNED

REASSIGN OWNED — change the ownership of database objects owned by a database role

## Synopsis

```
REASSIGN OWNED BY { old_role | CURRENT_USER | SESSION_USER } [, ...]  
                TO { new_role | CURRENT_USER | SESSION_USER }
```

## Description

REASSIGN OWNED instructs the system to change the ownership of database objects owned by any of the *old\_roles* to *new\_role*.

## Parameters

*old\_role*

The name of a role. The ownership of all the objects within the current database, and of all shared objects (databases, tablespaces), owned by this role will be reassigned to *new\_role*.

*new\_role*

The name of the role that will be made the new owner of the affected objects.

## Notes

REASSIGN OWNED is often used to prepare for the removal of one or more roles. Because REASSIGN OWNED does not affect objects within other databases, it is usually necessary to execute this command in each database that contains objects owned by a role that is to be removed.

REASSIGN OWNED requires membership on both the source role(s) and the target role.

The [DROP OWNED](#) command is an alternative that simply drops all the database objects owned by one or more roles.

The REASSIGN OWNED command does not affect any privileges granted to the *old\_roles* on objects that are not owned by them. Likewise, it does not affect default privileges created with ALTER DEFAULT PRIVILEGES. Use DROP OWNED to revoke such privileges.

See [Section 20.4](#) for more discussion.

## Compatibility

The REASSIGN OWNED command is a Postgres Pro extension.

## See Also

[DROP OWNED](#), [DROP ROLE](#), [ALTER DATABASE](#)

---

# REFRESH MATERIALIZED VIEW

REFRESH MATERIALIZED VIEW — replace the contents of a materialized view

## Synopsis

```
REFRESH MATERIALIZED VIEW [ CONCURRENTLY ] name
[ WITH [ NO ] DATA ]
```

## Description

REFRESH MATERIALIZED VIEW completely replaces the contents of a materialized view. To execute this command you must be the owner of the materialized view. The old contents are discarded. If WITH DATA is specified (or defaults) the backing query is executed to provide the new data, and the materialized view is left in a scannable state. If WITH NO DATA is specified no new data is generated and the materialized view is left in an unscannable state.

CONCURRENTLY and WITH NO DATA may not be specified together.

## Parameters

CONCURRENTLY

Refresh the materialized view without locking out concurrent selects on the materialized view. Without this option a refresh which affects a lot of rows will tend to use fewer resources and complete more quickly, but could block other connections which are trying to read from the materialized view. This option may be faster in cases where a small number of rows are affected.

This option is only allowed if there is at least one UNIQUE index on the materialized view which uses only column names and includes all rows; that is, it must not be an expression index or include a WHERE clause.

This option may not be used when the materialized view is not already populated.

Even with this option only one REFRESH at a time may run against any one materialized view.

*name*

The name (optionally schema-qualified) of the materialized view to refresh.

## Notes

If there is an ORDER BY clause in the materialized view's defining query, the original contents of the materialized view will be ordered that way; but REFRESH MATERIALIZED VIEW does not guarantee to preserve that ordering.

## Examples

This command will replace the contents of the materialized view called `order_summary` using the query from the materialized view's definition, and leave it in a scannable state:

```
REFRESH MATERIALIZED VIEW order_summary;
```

This command will free storage associated with the materialized view `annual_statistics_basis` and leave it in an unscannable state:

```
REFRESH MATERIALIZED VIEW annual_statistics_basis WITH NO DATA;
```

## Compatibility

REFRESH MATERIALIZED VIEW is a Postgres Pro extension.

**See Also**

[CREATE MATERIALIZED VIEW](#), [ALTER MATERIALIZED VIEW](#), [DROP MATERIALIZED VIEW](#)

---

# REINDEX

REINDEX — rebuild indexes

## Synopsis

```
REINDEX [ ( option [, ...] ) ] { INDEX | TABLE | SCHEMA | DATABASE | SYSTEM }  
[ CONCURRENTLY ] name
```

where *option* can be one of:

VERBOSE

## Description

REINDEX rebuilds an index using the data stored in the index's table, replacing the old copy of the index. There are several scenarios in which to use REINDEX:

- An index has become corrupted, and no longer contains valid data. Although in theory this should never happen, in practice indexes can become corrupted due to software bugs or hardware failures. REINDEX provides a recovery method.
- An index has become “bloated”, that is it contains many empty or nearly-empty pages. This can occur with B-tree indexes in Postgres Pro under certain uncommon access patterns. REINDEX provides a way to reduce the space consumption of the index by writing a new version of the index without the dead pages. See [Section 23.2](#) for more information.
- You have altered a storage parameter (such as fillfactor) for an index, and wish to ensure that the change has taken full effect.
- If an index build fails with the CONCURRENTLY option, this index is left as “invalid”. Such indexes are useless but it can be convenient to use REINDEX to rebuild them. Note that only REINDEX INDEX is able to perform a concurrent build on an invalid index.

## Parameters

INDEX

Recreate the specified index.

TABLE

Recreate all indexes of the specified table. If the table has a secondary “TOAST” table, that is reindexed as well.

SCHEMA

Recreate all indexes of the specified schema. If a table of this schema has a secondary “TOAST” table, that is reindexed as well. Indexes on shared system catalogs are also processed. This form of REINDEX cannot be executed inside a transaction block.

DATABASE

Recreate all indexes within the current database. Indexes on shared system catalogs are also processed. This form of REINDEX cannot be executed inside a transaction block.

SYSTEM

Recreate all indexes on system catalogs within the current database. Indexes on shared system catalogs are included. Indexes on user tables are not processed. This form of REINDEX cannot be executed inside a transaction block.

*name*

The name of the specific index, table, or database to be reindexed. Index and table names can be schema-qualified. Presently, `REINDEX DATABASE` and `REINDEX SYSTEM` can only reindex the current database, so their parameter must match the current database's name.

CONCURRENTLY

When this option is used, Postgres Pro will rebuild the index without taking any locks that prevent concurrent inserts, updates, or deletes on the table; whereas a standard index rebuild locks out writes (but not reads) on the table until it's done. There are several caveats to be aware of when using this option — see [Rebuilding Indexes Concurrently](#) below.

For temporary tables, `REINDEX` is always non-concurrent, as no other session can access them, and non-concurrent reindex is cheaper.

VERBOSE

Prints a progress report as each index is reindexed.

## Notes

If you suspect corruption of an index on a user table, you can simply rebuild that index, or all indexes on the table, using `REINDEX INDEX` or `REINDEX TABLE`.

Things are more difficult if you need to recover from corruption of an index on a system table. In this case it's important for the system to not have used any of the suspect indexes itself. (Indeed, in this sort of scenario you might find that server processes are crashing immediately at start-up, due to reliance on the corrupted indexes.) To recover safely, the server must be started with the `-P` option, which prevents it from using indexes for system catalog lookups.

One way to do this is to shut down the server and start a single-user Postgres Pro server with the `-P` option included on its command line. Then, `REINDEX DATABASE`, `REINDEX SYSTEM`, `REINDEX TABLE`, or `REINDEX INDEX` can be issued, depending on how much you want to reconstruct. If in doubt, use `REINDEX SYSTEM` to select reconstruction of all system indexes in the database. Then quit the single-user server session and restart the regular server. See the [postgres](#) reference page for more information about how to interact with the single-user server interface.

Alternatively, a regular server session can be started with `-P` included in its command line options. The method for doing this varies across clients, but in all libpq-based clients, it is possible to set the `PGOPTIONS` environment variable to `-P` before starting the client. Note that while this method does not require locking out other clients, it might still be wise to prevent other users from connecting to the damaged database until repairs have been completed.

`REINDEX` is similar to a drop and recreate of the index in that the index contents are rebuilt from scratch. However, the locking considerations are rather different. `REINDEX` locks out writes but not reads of the index's parent table. It also takes an `ACCESS EXCLUSIVE` lock on the specific index being processed, which will block reads that attempt to use that index. In contrast, `DROP INDEX` momentarily takes an `ACCESS EXCLUSIVE` lock on the parent table, blocking both writes and reads. The subsequent `CREATE INDEX` locks out writes but not reads; since the index is not there, no read will attempt to use it, meaning that there will be no blocking but reads might be forced into expensive sequential scans.

Reindexing a single index or table requires being the owner of that index or table. Reindexing a schema or database requires being the owner of that schema or database. Note specifically that it's thus possible for non-superusers to rebuild indexes of tables owned by other users. However, as a special exception, when `REINDEX DATABASE`, `REINDEX SCHEMA` or `REINDEX SYSTEM` is issued by a non-superuser, indexes on shared catalogs will be skipped unless the user owns the catalog (which typically won't be the case). Of course, superusers can always reindex anything.

Reindexing partitioned tables or partitioned indexes is not supported. Each individual partition can be reindexed separately instead.

## Rebuilding Indexes Concurrently

Rebuilding an index can interfere with regular operation of a database. Normally Postgres Pro locks the table whose index is rebuilt against writes and performs the entire index build with a single scan of the table. Other transactions can still read the table, but if they try to insert, update, or delete rows in the table they will block until the index rebuild is finished. This could have a severe effect if the system is a live production database. Very large tables can take many hours to be indexed, and even for smaller tables, an index rebuild can lock out writers for periods that are unacceptably long for a production system.

Postgres Pro supports rebuilding indexes with minimum locking of writes. This method is invoked by specifying the `CONCURRENTLY` option of `REINDEX`. When this option is used, Postgres Pro must perform two scans of the table for each index that needs to be rebuilt and wait for termination of all existing transactions that could potentially use the index. This method requires more total work than a standard index rebuild and takes significantly longer to complete as it needs to wait for unfinished transactions that might modify the index. However, since it allows normal operations to continue while the index is being rebuilt, this method is useful for rebuilding indexes in a production environment. Of course, the extra CPU, memory and I/O load imposed by the index rebuild may slow down other operations.

The following steps occur in a concurrent reindex. Each step is run in a separate transaction. If there are multiple indexes to be rebuilt, then each step loops through all the indexes before moving to the next step.

1. A new transient index definition is added to the catalog `pg_index`. This definition will be used to replace the old index. A `SHARE UPDATE EXCLUSIVE` lock at session level is taken on the indexes being reindexed as well as their associated tables to prevent any schema modification while processing.
2. A first pass to build the index is done for each new index. Once the index is built, its flag `pg_index.indisready` is switched to “true” to make it ready for inserts, making it visible to other sessions once the transaction that performed the build is finished. This step is done in a separate transaction for each index.
3. Then a second pass is performed to add tuples that were added while the first pass was running. This step is also done in a separate transaction for each index.
4. All the constraints that refer to the index are changed to refer to the new index definition, and the names of the indexes are changed. At this point, `pg_index.indisvalid` is switched to “true” for the new index and to “false” for the old, and a cache invalidation is done causing all sessions that referenced the old index to be invalidated.
5. The old indexes have `pg_index.indisready` switched to “false” to prevent any new tuple insertions, after waiting for running queries that might reference the old index to complete.
6. The old indexes are dropped. The `SHARE UPDATE EXCLUSIVE` session locks for the indexes and the table are released.

If a problem arises while rebuilding the indexes, such as a uniqueness violation in a unique index, the `REINDEX` command will fail but leave behind an “invalid” new index in addition to the pre-existing one. This index will be ignored for querying purposes because it might be incomplete; however it will still consume update overhead. The `psql \d` command will report such an index as `INVALID`:

```
postgres=# \d tab
          Table "public.tab"
  Column | Type   | Modifiers
-----+-----+-----
   col   | integer |
Indexes:
    "idx" btree (col)
    "idx_ccnew" btree (col) INVALID
```

If the index marked `INVALID` is suffixed `ccnew`, then it corresponds to the transient index created during the concurrent operation, and the recommended recovery method is to drop it using `DROP INDEX`, then attempt `REINDEX CONCURRENTLY` again. If the invalid index is instead suffixed `ccold`, it corresponds to

the original index which could not be dropped; the recommended recovery method is to just drop said index, since the rebuild proper has been successful.

Regular index builds permit other regular index builds on the same table to occur simultaneously, but only one concurrent index build can occur on a table at a time. In both cases, no other types of schema modification on the table are allowed meanwhile. Another difference is that a regular `REINDEX TABLE` or `REINDEX INDEX` command can be performed within a transaction block, but `REINDEX CONCURRENTLY` cannot.

Like any long-running transaction, `REINDEX` on a table can affect which tuples can be removed by concurrent `VACUUM` on any other table.

`REINDEX SYSTEM` does not support `CONCURRENTLY` since system catalogs cannot be reindexed concurrently.

Furthermore, indexes for exclusion constraints cannot be reindexed concurrently. If such an index is named directly in this command, an error is raised. If a table or database with exclusion constraint indexes is reindexed concurrently, those indexes will be skipped. (It is possible to reindex such indexes without the `CONCURRENTLY` option.)

## Examples

Rebuild a single index:

```
REINDEX INDEX my_index;
```

Rebuild all the indexes on the table `my_table`:

```
REINDEX TABLE my_table;
```

Rebuild all indexes in a particular database, without trusting the system indexes to be valid already:

```
$ export PGOPTIONS="-P"
$ psql broken_db
...
broken_db=> REINDEX DATABASE broken_db;
broken_db=> \q
```

Rebuild indexes for a table, without blocking read and write operations on involved relations while reindexing is in progress:

```
REINDEX TABLE CONCURRENTLY my_broken_table;
```

## Compatibility

There is no `REINDEX` command in the SQL standard.

## See Also

[CREATE INDEX](#), [DROP INDEX](#), [reindexdb](#)

---

# RELEASE SAVEPOINT

RELEASE SAVEPOINT — destroy a previously defined savepoint

## Synopsis

```
RELEASE [ SAVEPOINT ] savepoint_name
```

## Description

RELEASE SAVEPOINT destroys a savepoint previously defined in the current transaction.

Destroying a savepoint makes it unavailable as a rollback point, but it has no other user visible behavior. It does not undo the effects of commands executed after the savepoint was established. (To do that, see [ROLLBACK TO SAVEPOINT](#).) Destroying a savepoint when it is no longer needed allows the system to reclaim some resources earlier than transaction end.

RELEASE SAVEPOINT also destroys all savepoints that were established after the named savepoint was established.

## Parameters

*savepoint\_name*

The name of the savepoint to destroy.

## Notes

Specifying a savepoint name that was not previously defined is an error.

It is not possible to release a savepoint when the transaction is in an aborted state.

If multiple savepoints have the same name, only the one that was most recently defined is released.

## Examples

To establish and later destroy a savepoint:

```
BEGIN;  
  INSERT INTO table1 VALUES (3);  
  SAVEPOINT my_savepoint;  
  INSERT INTO table1 VALUES (4);  
  RELEASE SAVEPOINT my_savepoint;  
COMMIT;
```

The above transaction will insert both 3 and 4.

## Compatibility

This command conforms to the SQL standard. The standard specifies that the key word `SAVEPOINT` is mandatory, but Postgres Pro allows it to be omitted.

---

# RESET

RESET — restore the value of a run-time parameter to the default value

## Synopsis

```
RESET configuration_parameter
RESET ALL
```

## Description

RESET restores run-time parameters to their default values. RESET is an alternative spelling for

```
SET configuration_parameter TO DEFAULT
```

Refer to [SET](#) for details.

The default value is defined as the value that the parameter would have had, if no SET had ever been issued for it in the current session. The actual source of this value might be a compiled-in default, the configuration file, command-line options, or per-database or per-user default settings. This is subtly different from defining it as “the value that the parameter had at session start”, because if the value came from the configuration file, it will be reset to whatever is specified by the configuration file now. See [Chapter 18](#) for details.

The transactional behavior of RESET is the same as SET: its effects will be undone by transaction rollback.

## Parameters

*configuration\_parameter*

Name of a settable run-time parameter. Available parameters are documented in [Chapter 18](#) and on the [SET](#) reference page.

ALL

Resets all settable run-time parameters to default values.

## Examples

Set the `timezone` configuration variable to its default value:

```
RESET timezone;
```

## Compatibility

RESET is a Postgres Pro extension.

# REVOKE

REVOKE — remove access privileges

## Synopsis

```
REVOKE [ GRANT OPTION FOR ]
    { { SELECT | INSERT | UPDATE | DELETE | TRUNCATE | REFERENCES | TRIGGER }
      [, ...] | ALL [ PRIVILEGES ] }
ON { [ TABLE ] table_name [, ...]
     | ALL TABLES IN SCHEMA schema_name [, ...] }
FROM role_specification [, ...]
[ CASCADE | RESTRICT ]
```

```
REVOKE [ GRANT OPTION FOR ]
    { { SELECT | INSERT | UPDATE | REFERENCES } ( column_name [, ...] )
      [, ...] | ALL [ PRIVILEGES ] ( column_name [, ...] ) }
ON [ TABLE ] table_name [, ...]
FROM role_specification [, ...]
[ CASCADE | RESTRICT ]
```

```
REVOKE [ GRANT OPTION FOR ]
    { { USAGE | SELECT | UPDATE }
      [, ...] | ALL [ PRIVILEGES ] }
ON { SEQUENCE sequence_name [, ...]
     | ALL SEQUENCES IN SCHEMA schema_name [, ...] }
FROM role_specification [, ...]
[ CASCADE | RESTRICT ]
```

```
REVOKE [ GRANT OPTION FOR ]
    { { CREATE | CONNECT | TEMPORARY | TEMP } [, ...] | ALL [ PRIVILEGES ] }
ON DATABASE database_name [, ...]
FROM role_specification [, ...]
[ CASCADE | RESTRICT ]
```

```
REVOKE [ GRANT OPTION FOR ]
    { USAGE | ALL [ PRIVILEGES ] }
ON DOMAIN domain_name [, ...]
FROM role_specification [, ...]
[ CASCADE | RESTRICT ]
```

```
REVOKE [ GRANT OPTION FOR ]
    { USAGE | ALL [ PRIVILEGES ] }
ON FOREIGN DATA WRAPPER fdw_name [, ...]
FROM role_specification [, ...]
[ CASCADE | RESTRICT ]
```

```
REVOKE [ GRANT OPTION FOR ]
    { USAGE | ALL [ PRIVILEGES ] }
ON FOREIGN SERVER server_name [, ...]
FROM role_specification [, ...]
[ CASCADE | RESTRICT ]
```

```
REVOKE [ GRANT OPTION FOR ]
    { EXECUTE | ALL [ PRIVILEGES ] }
ON { { FUNCTION | PROCEDURE | ROUTINE } function_name [ ( [ [ argmode ] [ arg_name
] arg_type [, ...] ] ) ] [, ...]
```

## REVOKE

---

```
        | ALL { FUNCTIONS | PROCEDURES | ROUTINES } IN SCHEMA schema_name [, ...] }
FROM role_specification [, ...]
[ CASCADE | RESTRICT ]
```

```
REVOKE [ GRANT OPTION FOR ]
      { USAGE | ALL [ PRIVILEGES ] }
ON LANGUAGE lang_name [, ...]
FROM role_specification [, ...]
[ CASCADE | RESTRICT ]
```

```
REVOKE [ GRANT OPTION FOR ]
      { { SELECT | UPDATE } [, ...] | ALL [ PRIVILEGES ] }
ON LARGE OBJECT loid [, ...]
FROM role_specification [, ...]
[ CASCADE | RESTRICT ]
```

```
REVOKE [ GRANT OPTION FOR ]
      { { CREATE | USAGE } [, ...] | ALL [ PRIVILEGES ] }
ON SCHEMA schema_name [, ...]
FROM role_specification [, ...]
[ CASCADE | RESTRICT ]
```

```
REVOKE [ GRANT OPTION FOR ]
      { CREATE | ALL [ PRIVILEGES ] }
ON TABLESPACE tablespace_name [, ...]
FROM role_specification [, ...]
[ CASCADE | RESTRICT ]
```

```
REVOKE [ GRANT OPTION FOR ]
      { USAGE | ALL [ PRIVILEGES ] }
ON TYPE type_name [, ...]
FROM role_specification [, ...]
[ CASCADE | RESTRICT ]
```

```
REVOKE [ ADMIN OPTION FOR ]
      role_name [, ...] FROM role_specification [, ...]
[ GRANTED BY role_specification ]
[ CASCADE | RESTRICT ]
```

where *role\_specification* can be:

```
    [ GROUP ] role_name
| PUBLIC
| CURRENT_USER
| SESSION_USER
```

## Description

The **REVOKE** command revokes previously granted privileges from one or more roles. The key word **PUBLIC** refers to the implicitly defined group of all roles.

See the description of the **GRANT** command for the meaning of the privilege types.

Note that any particular role will have the sum of privileges granted directly to it, privileges granted to any role it is presently a member of, and privileges granted to **PUBLIC**. Thus, for example, revoking **SELECT** privilege from **PUBLIC** does not necessarily mean that all roles have lost **SELECT** privilege on the object: those who have it granted directly or via another role will still have it. Similarly, revoking **SELECT** from a user might not prevent that user from using **SELECT** if **PUBLIC** or another membership role still has **SELECT** rights.

If `GRANT OPTION FOR` is specified, only the grant option for the privilege is revoked, not the privilege itself. Otherwise, both the privilege and the grant option are revoked.

If a user holds a privilege with grant option and has granted it to other users then the privileges held by those other users are called dependent privileges. If the privilege or the grant option held by the first user is being revoked and dependent privileges exist, those dependent privileges are also revoked if `CASCADE` is specified; if it is not, the revoke action will fail. This recursive revocation only affects privileges that were granted through a chain of users that is traceable to the user that is the subject of this `REVOKE` command. Thus, the affected users might effectively keep the privilege if it was also granted through other users.

When revoking privileges on a table, the corresponding column privileges (if any) are automatically revoked on each column of the table, as well. On the other hand, if a role has been granted privileges on a table, then revoking the same privileges from individual columns will have no effect.

When revoking membership in a role, `GRANT OPTION` is instead called `ADMIN OPTION`, but the behavior is similar. This form of the command also allows a `GRANTED BY` option, but that option is currently ignored (except for checking the existence of the named role). Note also that this form of the command does not allow the noise word `GROUP` in *role\_specification*.

## Notes

A user can only revoke privileges that were granted directly by that user. If, for example, user A has granted a privilege with grant option to user B, and user B has in turn granted it to user C, then user A cannot revoke the privilege directly from C. Instead, user A could revoke the grant option from user B and use the `CASCADE` option so that the privilege is in turn revoked from user C. For another example, if both A and B have granted the same privilege to C, A can revoke their own grant but not B's grant, so C will still effectively have the privilege.

When a non-owner of an object attempts to `REVOKE` privileges on the object, the command will fail outright if the user has no privileges whatsoever on the object. As long as some privilege is available, the command will proceed, but it will revoke only those privileges for which the user has grant options. The `REVOKE ALL PRIVILEGES` forms will issue a warning message if no grant options are held, while the other forms will issue a warning if grant options for any of the privileges specifically named in the command are not held. (In principle these statements apply to the object owner as well, but since the owner is always treated as holding all grant options, the cases can never occur.)

If a superuser chooses to issue a `GRANT` or `REVOKE` command, the command is performed as though it were issued by the owner of the affected object. Since all privileges ultimately come from the object owner (possibly indirectly via chains of grant options), it is possible for a superuser to revoke all privileges, but this might require use of `CASCADE` as stated above.

`REVOKE` can also be done by a role that is not the owner of the affected object, but is a member of the role that owns the object, or is a member of a role that holds privileges `WITH GRANT OPTION` on the object. In this case the command is performed as though it were issued by the containing role that actually owns the object or holds the privileges `WITH GRANT OPTION`. For example, if table `t1` is owned by role `g1`, of which role `u1` is a member, then `u1` can revoke privileges on `t1` that are recorded as being granted by `g1`. This would include grants made by `u1` as well as by other members of role `g1`.

If the role executing `REVOKE` holds privileges indirectly via more than one role membership path, it is unspecified which containing role will be used to perform the command. In such cases it is best practice to use `SET ROLE` to become the specific role you want to do the `REVOKE` as. Failure to do so might lead to revoking privileges other than the ones you intended, or not revoking anything at all.

See [Section 5.7](#) for more information about specific privilege types, as well as how to inspect objects' privileges.

## Examples

Revoke insert privilege for the public on table `films`:

```
REVOKE INSERT ON films FROM PUBLIC;
```

Revoke all privileges from user manuel on view kinds:

```
REVOKE ALL PRIVILEGES ON kinds FROM manuel;
```

Note that this actually means “revoke all privileges that I granted”.

Revoke membership in role admins from user joe:

```
REVOKE admins FROM joe;
```

### Compatibility

The compatibility notes of the [GRANT](#) command apply analogously to REVOKE. The keyword RESTRICT or CASCADE is required according to the standard, but Postgres Pro assumes RESTRICT by default.

[GRANT](#), [ALTER DEFAULT PRIVILEGES](#)

---

# ROLLBACK

ROLLBACK — abort the current transaction

## Synopsis

```
ROLLBACK [ WORK | TRANSACTION ] [ AND [ NO ] CHAIN ]
```

## Description

ROLLBACK rolls back the current transaction and causes all the updates made by the transaction to be discarded.

## Parameters

WORK  
TRANSACTION

Optional key words. They have no effect.

AND CHAIN

If AND CHAIN is specified, a new transaction is immediately started with the same transaction characteristics (see [SET TRANSACTION](#)) as the just finished one. Otherwise, no new transaction is started.

## Notes

Use [COMMIT](#) to successfully terminate a transaction.

Issuing ROLLBACK outside of a transaction block emits a warning and otherwise has no effect. ROLLBACK AND CHAIN outside of a transaction block is an error.

## Examples

To abort all changes:

```
ROLLBACK;
```

## Compatibility

The command ROLLBACK conforms to the SQL standard. The form ROLLBACK TRANSACTION is a Postgres Pro extension.

## See Also

[BEGIN](#), [COMMIT](#), [ROLLBACK TO SAVEPOINT](#)

---

# ROLLBACK PREPARED

ROLLBACK PREPARED — cancel a transaction that was earlier prepared for two-phase commit

## Synopsis

```
ROLLBACK PREPARED transaction_id
```

## Description

ROLLBACK PREPARED rolls back a transaction that is in prepared state.

## Parameters

*transaction\_id*

The transaction identifier of the transaction that is to be rolled back.

## Notes

To roll back a prepared transaction, you must be either the same user that executed the transaction originally, or a superuser. But you do not have to be in the same session that executed the transaction.

This command cannot be executed inside a transaction block. The prepared transaction is rolled back immediately.

All currently available prepared transactions are listed in the [pg\\_prepared\\_xacts](#) system view.

## Examples

Roll back the transaction identified by the transaction identifier `foobar`:

```
ROLLBACK PREPARED 'foobar';
```

## Compatibility

ROLLBACK PREPARED is a Postgres Pro extension. It is intended for use by external transaction management systems, some of which are covered by standards (such as X/Open XA), but the SQL side of those systems is not standardized.

## See Also

[PREPARE TRANSACTION](#), [COMMIT PREPARED](#)

---

# ROLLBACK TO SAVEPOINT

ROLLBACK TO SAVEPOINT — roll back to a savepoint

## Synopsis

```
ROLLBACK [ WORK | TRANSACTION ] TO [ SAVEPOINT ] savepoint_name
```

## Description

Roll back all commands that were executed after the savepoint was established. The savepoint remains valid and can be rolled back to again later, if needed.

ROLLBACK TO SAVEPOINT implicitly destroys all savepoints that were established after the named savepoint.

## Parameters

*savepoint\_name*

The savepoint to roll back to.

## Notes

Use [RELEASE SAVEPOINT](#) to destroy a savepoint without discarding the effects of commands executed after it was established.

Specifying a savepoint name that has not been established is an error.

Cursors have somewhat non-transactional behavior with respect to savepoints. Any cursor that is opened inside a savepoint will be closed when the savepoint is rolled back. If a previously opened cursor is affected by a `FETCH` or `MOVE` command inside a savepoint that is later rolled back, the cursor remains at the position that `FETCH` left it pointing to (that is, the cursor motion caused by `FETCH` is not rolled back). Closing a cursor is not undone by rolling back, either. However, other side-effects caused by the cursor's query (such as side-effects of volatile functions called by the query) *are* rolled back if they occur during a savepoint that is later rolled back. A cursor whose execution causes a transaction to abort is put in a cannot-execute state, so while the transaction can be restored using `ROLLBACK TO SAVEPOINT`, the cursor can no longer be used.

## Examples

To undo the effects of the commands executed after `my_savepoint` was established:

```
ROLLBACK TO SAVEPOINT my_savepoint;
```

Cursor positions are not affected by savepoint rollback:

```
BEGIN;

DECLARE foo CURSOR FOR SELECT 1 UNION SELECT 2;

SAVEPOINT foo;

FETCH 1 FROM foo;
  ?column?
-----
         1

ROLLBACK TO SAVEPOINT foo;
```

```
FETCH 1 FROM foo;  
?column?  
-----  
2
```

```
COMMIT;
```

## Compatibility

The SQL standard specifies that the key word `SAVEPOINT` is mandatory, but Postgres Pro and Oracle allow it to be omitted. SQL allows only `WORK`, not `TRANSACTION`, as a noise word after `ROLLBACK`. Also, SQL has an optional clause `AND [ NO ] CHAIN` which is not currently supported by Postgres Pro. Otherwise, this command conforms to the SQL standard.

## See Also

[BEGIN](#), [COMMIT](#), [RELEASE SAVEPOINT](#), [ROLLBACK](#), [SAVEPOINT](#)

---

# SAVEPOINT

SAVEPOINT — define a new savepoint within the current transaction

## Synopsis

```
SAVEPOINT savepoint_name
```

## Description

SAVEPOINT establishes a new savepoint within the current transaction.

A savepoint is a special mark inside a transaction that allows all commands that are executed after it was established to be rolled back, restoring the transaction state to what it was at the time of the savepoint.

## Parameters

*savepoint\_name*

The name to give to the new savepoint.

## Notes

Use [ROLLBACK TO SAVEPOINT](#) to rollback to a savepoint. Use [RELEASE SAVEPOINT](#) to destroy a savepoint, keeping the effects of commands executed after it was established.

Savepoints can only be established when inside a transaction block. There can be multiple savepoints defined within a transaction.

## Examples

To establish a savepoint and later undo the effects of all commands executed after it was established:

```
BEGIN;  
    INSERT INTO table1 VALUES (1);  
    SAVEPOINT my_savepoint;  
    INSERT INTO table1 VALUES (2);  
    ROLLBACK TO SAVEPOINT my_savepoint;  
    INSERT INTO table1 VALUES (3);  
COMMIT;
```

The above transaction will insert the values 1 and 3, but not 2.

To establish and later destroy a savepoint:

```
BEGIN;  
    INSERT INTO table1 VALUES (3);  
    SAVEPOINT my_savepoint;  
    INSERT INTO table1 VALUES (4);  
    RELEASE SAVEPOINT my_savepoint;  
COMMIT;
```

The above transaction will insert both 3 and 4.

## Compatibility

SQL requires a savepoint to be destroyed automatically when another savepoint with the same name is established. In Postgres Pro, the old savepoint is kept, though only the more recent one will be used when rolling back or releasing. (Releasing the newer savepoint with `RELEASE SAVEPOINT` will cause the older one to again become accessible to `ROLLBACK TO SAVEPOINT` and `RELEASE SAVEPOINT`.) Otherwise, `SAVEPOINT` is fully SQL conforming.

**See Also**

[BEGIN](#), [COMMIT](#), [RELEASE SAVEPOINT](#), [ROLLBACK](#), [ROLLBACK TO SAVEPOINT](#)

---

# SECURITY LABEL

SECURITY LABEL — define or change a security label applied to an object

## Synopsis

```
SECURITY LABEL [ FOR provider ] ON
{
    TABLE object_name |
    COLUMN table_name.column_name |
    AGGREGATE aggregate_name ( aggregate_signature ) |
    DATABASE object_name |
    DOMAIN object_name |
    EVENT TRIGGER object_name |
    FOREIGN TABLE object_name
    FUNCTION function_name [ ( [ [ argmode ] [ argname ] argtype [, ...] ] ) ] |
    LARGE OBJECT large_object_oid |
    MATERIALIZED VIEW object_name |
    [ PROCEDURAL ] LANGUAGE object_name |

} IS 'label'
```

where *aggregate\_signature* is:

```
* |
[ argmode ] [ argname ] argtype [ , ... ] |
[ [ argmode ] [ argname ] argtype [ , ... ] ] ORDER BY [ argmode ] [ argname ] argtype
[ , ... ]
```

## Description

SECURITY LABEL applies a security label to a database object. An arbitrary number of security labels, one per label provider, can be associated with a given database object. Label providers are loadable modules which register themselves by using the function `register_label_provider`.

### Note

`register_label_provider` is not an SQL function; it can only be called from C code loaded into the backend.

The label provider determines whether a given label is valid and whether it is permissible to assign that label to a given object. The meaning of a given label is likewise at the discretion of the label provider. Postgres Pro places no restrictions on whether or how a label provider must interpret security labels; it merely provides a mechanism for storing them. In practice, this facility is intended to allow integration with label-based mandatory access control (MAC) systems such as SELinux. Such systems make all access control decisions based on object labels, rather than traditional discretionary access control (DAC) concepts such as users and groups.

## Parameters

*object\_name*  
*table\_name.column\_name*  
*aggregate\_name*  
*function\_name*  
*procedure\_name*  
*routine\_name*

The name of the object to be labeled. Names of tables, aggregates, domains, foreign tables, functions, procedures, routines, sequences, types, and views can be schema-qualified.

*provider*

The name of the provider with which this label is to be associated. The named provider must be loaded and must consent to the proposed labeling operation. If exactly one provider is loaded, the provider name may be omitted for brevity.

*argmode*

The mode of a function, procedure, or aggregate argument: IN, OUT, INOUT, or VARIADIC. If omitted, the default is IN. Note that SECURITY LABEL does not actually pay any attention to OUT arguments, since only the input arguments are needed to determine the function's identity. So it is sufficient to list the IN, INOUT, and VARIADIC arguments.

*argname*

The name of a function, procedure, or aggregate argument. Note that SECURITY LABEL does not actually pay any attention to argument names, since only the argument data types are needed to determine the function's identity.

*argtype*

The data type of a function, procedure, or aggregate argument.

*large\_object\_oid*

The OID of the large object.

PROCEDURAL

This is a noise word.

*label*

The new security label, written as a string literal; or NULL to drop the security label.

## Examples

The following example shows how the security label of a table might be changed.

```
SECURITY LABEL FOR selinux ON TABLE mytable IS 'system_u:object_r:sepgsql_table_t:s0';
```

## Compatibility

There is no SECURITY LABEL command in the SQL standard.

# SELECT

SELECT, TABLE, WITH — retrieve rows from a table or view

## Synopsis

```
[ WITH [ RECURSIVE ] with_query [, ...] ]
SELECT [ ALL | DISTINCT [ ON ( expression [, ...] ) ] ]
    [ * | expression [ [ AS ] output_name ] [, ...] ]
    [ FROM from_item [, ...] ]
    [ WHERE condition ]
    [ GROUP BY grouping_element [, ...] ]
    [ HAVING condition ]
    [ WINDOW window_name AS ( window_definition ) [, ...] ]
    [ { UNION | INTERSECT | EXCEPT } [ ALL | DISTINCT ] select ]
    [ ORDER BY expression [ ASC | DESC | USING operator ] [ NULLS { FIRST | LAST } ]
[, ...] ]
    [ LIMIT { count | ALL } ]
    [ OFFSET start [ ROW | ROWS ] ]
    [ FETCH { FIRST | NEXT } [ count ] { ROW | ROWS } { ONLY | WITH TIES } ]
    [ FOR { UPDATE | NO KEY UPDATE | SHARE | KEY SHARE } [ OF table_name [, ...] ]
[ NOWAIT | SKIP LOCKED ] [...]
```

where *from\_item* can be one of:

```
[ ONLY ] table_name [ * ] [ [ AS ] alias [ ( column_alias [, ...] ) ] ]
    [ TABLESAMPLE sampling_method ( argument [, ...] ) [ REPEATABLE ( seed
) ] ]
[ LATERAL ] ( select ) [ AS ] alias [ ( column_alias [, ...] ) ]
with_query_name [ [ AS ] alias [ ( column_alias [, ...] ) ] ]
[ LATERAL ] function_name ( [ argument [, ...] ] )
    [ WITH ORDINALITY ] [ [ AS ] alias [ ( column_alias [, ...] ) ] ]
[ LATERAL ] function_name ( [ argument [, ...] ] ) [ AS ] alias ( column_definition
[, ...] )
[ LATERAL ] function_name ( [ argument [, ...] ] ) AS ( column_definition [, ...] )
[ LATERAL ] ROWS FROM( function_name ( [ argument [, ...] ] ) [ AS
( column_definition [, ...] ) ] [, ...] )
    [ WITH ORDINALITY ] [ [ AS ] alias [ ( column_alias [, ...] ) ] ]
    from_item [ NATURAL ] join_type from_item [ ON join_condition | USING ( join_column
[, ...] ) ]
```

and *grouping\_element* can be one of:

```
( )
expression
( expression [, ...] )
ROLLUP ( { expression | ( expression [, ...] ) } [, ...] )
CUBE ( { expression | ( expression [, ...] ) } [, ...] )
GROUPING SETS ( grouping_element [, ...] )
```

and *with\_query* is:

```
with_query_name [ ( column_name [, ...] ) ] AS [ [ NOT ] MATERIALIZED ] ( select
| values | insert | update | delete )
```

```
TABLE [ ONLY ] table_name [ * ]
```

## Description

SELECT retrieves rows from zero or more tables. The general processing of SELECT is as follows:

1. All queries in the WITH list are computed. These effectively serve as temporary tables that can be referenced in the FROM list. A WITH query that is referenced more than once in FROM is computed only once, unless specified otherwise with NOT MATERIALIZED. (See [WITH Clause](#) below.)
2. All elements in the FROM list are computed. (Each element in the FROM list is a real or virtual table.) If more than one element is specified in the FROM list, they are cross-joined together. (See [FROM Clause](#) below.)
3. If the WHERE clause is specified, all rows that do not satisfy the condition are eliminated from the output. (See [WHERE Clause](#) below.)
4. If the GROUP BY clause is specified, or if there are aggregate function calls, the output is combined into groups of rows that match on one or more values, and the results of aggregate functions are computed. If the HAVING clause is present, it eliminates groups that do not satisfy the given condition. (See [GROUP BY Clause](#) and [HAVING Clause](#) below.)
5. The actual output rows are computed using the SELECT output expressions for each selected row or row group. (See [SELECT List](#) below.)
6. SELECT DISTINCT eliminates duplicate rows from the result. SELECT DISTINCT ON eliminates rows that match on all the specified expressions. SELECT ALL (the default) will return all candidate rows, including duplicates. (See [DISTINCT Clause](#) below.)
7. Using the operators UNION, INTERSECT, and EXCEPT, the output of more than one SELECT statement can be combined to form a single result set. The UNION operator returns all rows that are in one or both of the result sets. The INTERSECT operator returns all rows that are strictly in both result sets. The EXCEPT operator returns the rows that are in the first result set but not in the second. In all three cases, duplicate rows are eliminated unless ALL is specified. The noise word DISTINCT can be added to explicitly specify eliminating duplicate rows. Notice that DISTINCT is the default behavior here, even though ALL is the default for SELECT itself. (See [UNION Clause](#), [INTERSECT Clause](#), and [EXCEPT Clause](#) below.)
8. If the ORDER BY clause is specified, the returned rows are sorted in the specified order. If ORDER BY is not given, the rows are returned in whatever order the system finds fastest to produce. (See [ORDER BY Clause](#) below.)
9. If the LIMIT (or FETCH FIRST) or OFFSET clause is specified, the SELECT statement only returns a subset of the result rows. (See [LIMIT Clause](#) below.)
10. If FOR UPDATE, FOR NO KEY UPDATE, FOR SHARE or FOR KEY SHARE is specified, the SELECT statement locks the selected rows against concurrent updates. (See [The Locking Clause](#) below.)

You must have SELECT privilege on each column used in a SELECT command. The use of FOR NO KEY UPDATE, FOR UPDATE, FOR SHARE or FOR KEY SHARE requires UPDATE privilege as well (for at least one column of each table so selected).

## Parameters

### WITH Clause

The WITH clause allows you to specify one or more subqueries that can be referenced by name in the primary query. The subqueries effectively act as temporary tables or views for the duration of the primary query. Each subquery can be a SELECT, TABLE, VALUES, INSERT, UPDATE or DELETE statement. When writing a data-modifying statement (INSERT, UPDATE or DELETE) in WITH, it is usual to include a RETURNING clause. It is the output of RETURNING, *not* the underlying table that the statement modifies, that forms the temporary table that is read by the primary query. If RETURNING is omitted, the statement is still executed, but it produces no output so it cannot be referenced as a table by the primary query.

A name (without schema qualification) must be specified for each `WITH` query. Optionally, a list of column names can be specified; if this is omitted, the column names are inferred from the subquery.

If `RECURSIVE` is specified, it allows a `SELECT` subquery to reference itself by name. Such a subquery must have the form

```
non_recursive_term UNION [ ALL | DISTINCT ] recursive_term
```

where the recursive self-reference must appear on the right-hand side of the `UNION`. Only one recursive self-reference is permitted per query. Recursive data-modifying statements are not supported, but you can use the results of a recursive `SELECT` query in a data-modifying statement. See [Section 7.8](#) for an example.

Another effect of `RECURSIVE` is that `WITH` queries need not be ordered: a query can reference another one that is later in the list. (However, circular references, or mutual recursion, are not implemented.) Without `RECURSIVE`, `WITH` queries can only reference sibling `WITH` queries that are earlier in the `WITH` list.

When there are multiple queries in the `WITH` clause, `RECURSIVE` should be written only once, immediately after `WITH`. It applies to all queries in the `WITH` clause, though it has no effect on queries that do not use recursion or forward references.

The primary query and the `WITH` queries are all (notionally) executed at the same time. This implies that the effects of a data-modifying statement in `WITH` cannot be seen from other parts of the query, other than by reading its `RETURNING` output. If two such data-modifying statements attempt to modify the same row, the results are unspecified.

A key property of `WITH` queries is that they are normally evaluated only once per execution of the primary query, even if the primary query refers to them more than once. In particular, data-modifying statements are guaranteed to be executed once and only once, regardless of whether the primary query reads all or any of their output.

However, a `WITH` query can be marked `NOT MATERIALIZED` to remove this guarantee. In that case, the `WITH` query can be folded into the primary query much as though it were a simple sub-`SELECT` in the primary query's `FROM` clause. This results in duplicate computations if the primary query refers to that `WITH` query more than once; but if each such use requires only a few rows of the `WITH` query's total output, `NOT MATERIALIZED` can provide a net savings by allowing the queries to be optimized jointly. `NOT MATERIALIZED` is ignored if it is attached to a `WITH` query that is recursive or is not side-effect-free (i.e., is not a plain `SELECT` containing no volatile functions).

By default, a side-effect-free `WITH` query is folded into the primary query if it is used exactly once in the primary query's `FROM` clause. This allows joint optimization of the two query levels in situations where that should be semantically invisible. However, such folding can be prevented by marking the `WITH` query as `MATERIALIZED`. That might be useful, for example, if the `WITH` query is being used as an optimization fence to prevent the planner from choosing a bad plan. Postgres Pro versions before v12 never did such folding, so queries written for older versions might rely on `WITH` to act as an optimization fence.

See [Section 7.8](#) for additional information.

## FROM Clause

The `FROM` clause specifies one or more source tables for the `SELECT`. If multiple sources are specified, the result is the Cartesian product (cross join) of all the sources. But usually qualification conditions are added (via `WHERE`) to restrict the returned rows to a small subset of the Cartesian product.

The `FROM` clause can contain the following elements:

```
table_name
```

The name (optionally schema-qualified) of an existing table or view. If `ONLY` is specified before the table name, only that table is scanned. If `ONLY` is not specified, the table and all its descendant tables

(if any) are scanned. Optionally, `*` can be specified after the table name to explicitly indicate that descendant tables are included.

#### *alias*

A substitute name for the `FROM` item containing the alias. An alias is used for brevity or to eliminate ambiguity for self-joins (where the same table is scanned multiple times). When an alias is provided, it completely hides the actual name of the table or function; for example given `FROM foo AS f`, the remainder of the `SELECT` must refer to this `FROM` item as `f` not `foo`. If an alias is written, a column alias list can also be written to provide substitute names for one or more columns of the table.

```
TABLESAMPLE sampling_method ( argument [, ...] ) [ REPEATABLE ( seed ) ]
```

A `TABLESAMPLE` clause after a *table\_name* indicates that the specified *sampling\_method* should be used to retrieve a subset of the rows in that table. This sampling precedes the application of any other filters such as `WHERE` clauses. The standard Postgres Pro distribution includes two sampling methods, `BERNOULLI` and `SYSTEM`, and other sampling methods can be installed in the database via extensions.

The `BERNOULLI` and `SYSTEM` sampling methods each accept a single *argument* which is the fraction of the table to sample, expressed as a percentage between 0 and 100. This argument can be any real-valued expression. (Other sampling methods might accept more or different arguments.) These two methods each return a randomly-chosen sample of the table that will contain approximately the specified percentage of the table's rows. The `BERNOULLI` method scans the whole table and selects or ignores individual rows independently with the specified probability. The `SYSTEM` method does block-level sampling with each block having the specified chance of being selected; all rows in each selected block are returned. The `SYSTEM` method is significantly faster than the `BERNOULLI` method when small sampling percentages are specified, but it may return a less-random sample of the table as a result of clustering effects.

The optional `REPEATABLE` clause specifies a *seed* number or expression to use for generating random numbers within the sampling method. The seed value can be any non-null floating-point value. Two queries that specify the same seed and *argument* values will select the same sample of the table, if the table has not been changed meanwhile. But different seed values will usually produce different samples. If `REPEATABLE` is not given then a new random sample is selected for each query, based upon a system-generated seed. Note that some add-on sampling methods do not accept `REPEATABLE`, and will always produce new samples on each use.

#### *select*

A sub-`SELECT` can appear in the `FROM` clause. This acts as though its output were created as a temporary table for the duration of this single `SELECT` command. Note that the sub-`SELECT` must be surrounded by parentheses, and an alias *must* be provided for it. A `VALUES` command can also be used here.

#### *with\_query\_name*

A `WITH` query is referenced by writing its name, just as though the query's name were a table name. (In fact, the `WITH` query hides any real table of the same name for the purposes of the primary query. If necessary, you can refer to a real table of the same name by schema-qualifying the table's name.) An alias can be provided in the same way as for a table.

#### *function\_name*

Function calls can appear in the `FROM` clause. (This is especially useful for functions that return result sets, but any function can be used.) This acts as though the function's output were created as a temporary table for the duration of this single `SELECT` command. If the function's result type is composite (including the case of a function with multiple `OUT` parameters), each attribute becomes a separate column in the implicit table.

When the optional `WITH ORDINALITY` clause is added to the function call, an additional column of type `bigint` will be appended to the function's result column(s). This column numbers the rows of the function's result set, starting from 1. By default, this column is named `ordinality`.

An alias can be provided in the same way as for a table. If an alias is written, a column alias list can also be written to provide substitute names for one or more attributes of the function's composite return type, including the ordinality column if present.

Multiple function calls can be combined into a single `FROM`-clause item by surrounding them with `ROWS FROM( ... )`. The output of such an item is the concatenation of the first row from each function, then the second row from each function, etc. If some of the functions produce fewer rows than others, null values are substituted for the missing data, so that the total number of rows returned is always the same as for the function that produced the most rows.

If the function has been defined as returning the `record` data type, then an alias or the key word `AS` must be present, followed by a column definition list in the form `( column_name data_type [, ... ])`. The column definition list must match the actual number and types of columns returned by the function.

When using the `ROWS FROM( ... )` syntax, if one of the functions requires a column definition list, it's preferred to put the column definition list after the function call inside `ROWS FROM( ... )`. A column definition list can be placed after the `ROWS FROM( ... )` construct only if there's just a single function and no `WITH ORDINALITY` clause.

To use `ORDINALITY` together with a column definition list, you must use the `ROWS FROM( ... )` syntax and put the column definition list inside `ROWS FROM( ... )`.

#### *join\_type*

One of

- `[ INNER ] JOIN`
- `LEFT [ OUTER ] JOIN`
- `RIGHT [ OUTER ] JOIN`
- `FULL [ OUTER ] JOIN`
- `CROSS JOIN`

For the `INNER` and `OUTER` join types, a join condition must be specified, namely exactly one of `NATURAL`, `ON join_condition`, or `USING (join_column [, ...])`. See below for the meaning. For `CROSS JOIN`, none of these clauses can appear.

A `JOIN` clause combines two `FROM` items, which for convenience we will refer to as “tables”, though in reality they can be any type of `FROM` item. Use parentheses if necessary to determine the order of nesting. In the absence of parentheses, `JOINS` nest left-to-right. In any case `JOIN` binds more tightly than the commas separating `FROM`-list items.

`CROSS JOIN` and `INNER JOIN` produce a simple Cartesian product, the same result as you get from listing the two tables at the top level of `FROM`, but restricted by the join condition (if any). `CROSS JOIN` is equivalent to `INNER JOIN ON (TRUE)`, that is, no rows are removed by qualification. These join types are just a notational convenience, since they do nothing you couldn't do with plain `FROM` and `WHERE`.

`LEFT OUTER JOIN` returns all rows in the qualified Cartesian product (i.e., all combined rows that pass its join condition), plus one copy of each row in the left-hand table for which there was no right-hand row that passed the join condition. This left-hand row is extended to the full width of the joined table by inserting null values for the right-hand columns. Note that only the `JOIN` clause's own condition is considered while deciding which rows have matches. Outer conditions are applied afterwards.

Conversely, `RIGHT OUTER JOIN` returns all the joined rows, plus one row for each unmatched right-hand row (extended with nulls on the left). This is just a notational convenience, since you could convert it to a `LEFT OUTER JOIN` by switching the left and right tables.

`FULL OUTER JOIN` returns all the joined rows, plus one row for each unmatched left-hand row (extended with nulls on the right), plus one row for each unmatched right-hand row (extended with nulls on the left).

ON *join\_condition*

*join\_condition* is an expression resulting in a value of type `boolean` (similar to a `WHERE` clause) that specifies which rows in a join are considered to match.

USING ( *join\_column* [, ...] )

A clause of the form `USING ( a, b, ... )` is shorthand for `ON left_table.a = right_table.a AND left_table.b = right_table.b ...`. Also, `USING` implies that only one of each pair of equivalent columns will be included in the join output, not both.

NATURAL

`NATURAL` is shorthand for a `USING` list that mentions all columns in the two tables that have matching names. If there are no common column names, `NATURAL` is equivalent to `ON TRUE`.

LATERAL

The `LATERAL` key word can precede a sub-`SELECT FROM` item. This allows the sub-`SELECT` to refer to columns of `FROM` items that appear before it in the `FROM` list. (Without `LATERAL`, each sub-`SELECT` is evaluated independently and so cannot cross-reference any other `FROM` item.)

`LATERAL` can also precede a function-call `FROM` item, but in this case it is a noise word, because the function expression can refer to earlier `FROM` items in any case.

A `LATERAL` item can appear at top level in the `FROM` list, or within a `JOIN` tree. In the latter case it can also refer to any items that are on the left-hand side of a `JOIN` that it is on the right-hand side of.

When a `FROM` item contains `LATERAL` cross-references, evaluation proceeds as follows: for each row of the `FROM` item providing the cross-referenced column(s), or set of rows of multiple `FROM` items providing the columns, the `LATERAL` item is evaluated using that row or row set's values of the columns. The resulting row(s) are joined as usual with the rows they were computed from. This is repeated for each row or set of rows from the column source table(s).

The column source table(s) must be `INNER` or `LEFT` joined to the `LATERAL` item, else there would not be a well-defined set of rows from which to compute each set of rows for the `LATERAL` item. Thus, although a construct such as `X RIGHT JOIN LATERAL Y` is syntactically valid, it is not actually allowed for `Y` to reference `X`.

## WHERE Clause

The optional `WHERE` clause has the general form

`WHERE condition`

where *condition* is any expression that evaluates to a result of type `boolean`. Any row that does not satisfy this condition will be eliminated from the output. A row satisfies the condition if it returns true when the actual row values are substituted for any variable references.

## GROUP BY Clause

The optional `GROUP BY` clause has the general form

`GROUP BY grouping_element [, ...]`

`GROUP BY` will condense into a single row all selected rows that share the same values for the grouped expressions. An *expression* used inside a *grouping\_element* can be an input column name, or the name or ordinal number of an output column (`SELECT` list item), or an arbitrary expression formed from input-column values. In case of ambiguity, a `GROUP BY` name will be interpreted as an input-column name rather than an output column name.

If any of `GROUPING SETS`, `ROLLUP` or `CUBE` are present as grouping elements, then the `GROUP BY` clause as a whole defines some number of independent *grouping sets*. The effect of this is equivalent to

constructing a `UNION ALL` between subqueries with the individual grouping sets as their `GROUP BY` clauses. For further details on the handling of grouping sets see [Section 7.2.4](#).

Aggregate functions, if any are used, are computed across all rows making up each group, producing a separate value for each group. (If there are aggregate functions but no `GROUP BY` clause, the query is treated as having a single group comprising all the selected rows.) The set of rows fed to each aggregate function can be further filtered by attaching a `FILTER` clause to the aggregate function call; see [Section 4.2.7](#) for more information. When a `FILTER` clause is present, only those rows matching it are included in the input to that aggregate function.

When `GROUP BY` is present, or any aggregate functions are present, it is not valid for the `SELECT` list expressions to refer to ungrouped columns except within aggregate functions or when the ungrouped column is functionally dependent on the grouped columns, since there would otherwise be more than one possible value to return for an ungrouped column. A functional dependency exists if the grouped columns (or a subset thereof) are the primary key of the table containing the ungrouped column.

Keep in mind that all aggregate functions are evaluated before evaluating any “scalar” expressions in the `HAVING` clause or `SELECT` list. This means that, for example, a `CASE` expression cannot be used to skip evaluation of an aggregate function; see [Section 4.2.14](#).

Currently, `FOR NO KEY UPDATE`, `FOR UPDATE`, `FOR SHARE` and `FOR KEY SHARE` cannot be specified with `GROUP BY`.

## HAVING Clause

The optional `HAVING` clause has the general form

```
HAVING condition
```

where *condition* is the same as specified for the `WHERE` clause.

`HAVING` eliminates group rows that do not satisfy the condition. `HAVING` is different from `WHERE`: `WHERE` filters individual rows before the application of `GROUP BY`, while `HAVING` filters group rows created by `GROUP BY`. Each column referenced in *condition* must unambiguously reference a grouping column, unless the reference appears within an aggregate function or the ungrouped column is functionally dependent on the grouping columns.

The presence of `HAVING` turns a query into a grouped query even if there is no `GROUP BY` clause. This is the same as what happens when the query contains aggregate functions but no `GROUP BY` clause. All the selected rows are considered to form a single group, and the `SELECT` list and `HAVING` clause can only reference table columns from within aggregate functions. Such a query will emit a single row if the `HAVING` condition is true, zero rows if it is not true.

Currently, `FOR NO KEY UPDATE`, `FOR UPDATE`, `FOR SHARE` and `FOR KEY SHARE` cannot be specified with `HAVING`.

## WINDOW Clause

The optional `WINDOW` clause has the general form

```
WINDOW window_name AS ( window_definition ) [, ...]
```

where *window\_name* is a name that can be referenced from `OVER` clauses or subsequent window definitions, and *window\_definition* is

```
[ existing_window_name ]
[ PARTITION BY expression [, ...] ]
[ ORDER BY expression [ ASC | DESC | USING operator ] [ NULLS { FIRST | LAST } ]
  [, ...] ]
[ frame_clause ]
```

If an *existing\_window\_name* is specified it must refer to an earlier entry in the `WINDOW` list; the new window copies its partitioning clause from that entry, as well as its ordering clause if any. In this case the

new window cannot specify its own `PARTITION BY` clause, and it can specify `ORDER BY` only if the copied window does not have one. The new window always uses its own frame clause; the copied window must not specify a frame clause.

The elements of the `PARTITION BY` list are interpreted in much the same fashion as elements of a `GROUP BY` clause, except that they are always simple expressions and never the name or number of an output column. Another difference is that these expressions can contain aggregate function calls, which are not allowed in a regular `GROUP BY` clause. They are allowed here because windowing occurs after grouping and aggregation.

Similarly, the elements of the `ORDER BY` list are interpreted in much the same fashion as elements of a statement-level `ORDER BY` clause, except that the expressions are always taken as simple expressions and never the name or number of an output column.

The optional *frame\_clause* defines the *window frame* for window functions that depend on the frame (not all do). The window frame is a set of related rows for each row of the query (called the *current row*). The *frame\_clause* can be one of

```
{ RANGE | ROWS | GROUPS } frame_start [ frame_exclusion ]
{ RANGE | ROWS | GROUPS } BETWEEN frame_start AND frame_end [ frame_exclusion ]
```

where *frame\_start* and *frame\_end* can be one of

```
UNBOUNDED PRECEDING
offset PRECEDING
CURRENT ROW
offset FOLLOWING
UNBOUNDED FOLLOWING
```

and *frame\_exclusion* can be one of

```
EXCLUDE CURRENT ROW
EXCLUDE GROUP
EXCLUDE TIES
EXCLUDE NO OTHERS
```

If *frame\_end* is omitted it defaults to `CURRENT ROW`. Restrictions are that *frame\_start* cannot be `UNBOUNDED FOLLOWING`, *frame\_end* cannot be `UNBOUNDED PRECEDING`, and the *frame\_end* choice cannot appear earlier in the above list of *frame\_start* and *frame\_end* options than the *frame\_start* choice does — for example `RANGE BETWEEN CURRENT ROW AND offset PRECEDING` is not allowed.

The default framing option is `RANGE UNBOUNDED PRECEDING`, which is the same as `RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW`; it sets the frame to be all rows from the partition start up through the current row's last *peer* (a row that the window's `ORDER BY` clause considers equivalent to the current row; all rows are peers if there is no `ORDER BY`). In general, `UNBOUNDED PRECEDING` means that the frame starts with the first row of the partition, and similarly `UNBOUNDED FOLLOWING` means that the frame ends with the last row of the partition, regardless of `RANGE`, `ROWS` or `GROUPS` mode. In `ROWS` mode, `CURRENT ROW` means that the frame starts or ends with the current row; but in `RANGE` or `GROUPS` mode it means that the frame starts or ends with the current row's first or last peer in the `ORDER BY` ordering. The `offset PRECEDING` and `offset FOLLOWING` options vary in meaning depending on the frame mode. In `ROWS` mode, the *offset* is an integer indicating that the frame starts or ends that many rows before or after the current row. In `GROUPS` mode, the *offset* is an integer indicating that the frame starts or ends that many peer groups before or after the current row's peer group, where a *peer group* is a group of rows that are equivalent according to the window's `ORDER BY` clause. In `RANGE` mode, use of an *offset* option requires that there be exactly one `ORDER BY` column in the window definition. Then the frame contains those rows whose ordering column value is no more than *offset* less than (for `PRECEDING`) or more than (for `FOLLOWING`) the current row's ordering column value. In these cases the data type of the *offset* expression depends on the data type of the ordering column. For numeric ordering columns it is typically of the same type as the ordering column, but for datetime ordering columns it is an *interval*. In all these cases, the value of the *offset* must be non-null and non-negative. Also, while the *offset* does not have to be a simple constant, it cannot contain variables, aggregate functions, or window functions.

The *frame\_exclusion* option allows rows around the current row to be excluded from the frame, even if they would be included according to the frame start and frame end options. `EXCLUDE CURRENT ROW` excludes the current row from the frame. `EXCLUDE GROUP` excludes the current row and its ordering peers from the frame. `EXCLUDE TIES` excludes any peers of the current row from the frame, but not the current row itself. `EXCLUDE NO OTHERS` simply specifies explicitly the default behavior of not excluding the current row or its peers.

Beware that the `ROWS` mode can produce unpredictable results if the `ORDER BY` ordering does not order the rows uniquely. The `RANGE` and `GROUPS` modes are designed to ensure that rows that are peers in the `ORDER BY` ordering are treated alike: all rows of a given peer group will be in the frame or excluded from it.

The purpose of a `WINDOW` clause is to specify the behavior of *window functions* appearing in the query's `SELECT list` or `ORDER BY` clause. These functions can reference the `WINDOW` clause entries by name in their `OVER` clauses. A `WINDOW` clause entry does not have to be referenced anywhere, however; if it is not used in the query it is simply ignored. It is possible to use window functions without any `WINDOW` clause at all, since a window function call can specify its window definition directly in its `OVER` clause. However, the `WINDOW` clause saves typing when the same window definition is needed for more than one window function.

Currently, `FOR NO KEY UPDATE`, `FOR UPDATE`, `FOR SHARE` and `FOR KEY SHARE` cannot be specified with `WINDOW`.

Window functions are described in detail in [Section 3.5](#), [Section 4.2.8](#), and [Section 7.2.5](#).

## SELECT List

The `SELECT list` (between the key words `SELECT` and `FROM`) specifies expressions that form the output rows of the `SELECT` statement. The expressions can (and usually do) refer to columns computed in the `FROM` clause.

Just as in a table, every output column of a `SELECT` has a name. In a simple `SELECT` this name is just used to label the column for display, but when the `SELECT` is a sub-query of a larger query, the name is seen by the larger query as the column name of the virtual table produced by the sub-query. To specify the name to use for an output column, write `AS output_name` after the column's expression. (You can omit `AS`, but only if the desired output name does not match any Postgres Pro keyword (see [Appendix C](#)). For protection against possible future keyword additions, it is recommended that you always either write `AS` or double-quote the output name.) If you do not specify a column name, a name is chosen automatically by Postgres Pro. If the column's expression is a simple column reference then the chosen name is the same as that column's name. In more complex cases a function or type name may be used, or the system may fall back on a generated name such as `?column?`.

An output column's name can be used to refer to the column's value in `ORDER BY` and `GROUP BY` clauses, but not in the `WHERE` or `HAVING` clauses; there you must write out the expression instead.

Instead of an expression, `*` can be written in the output list as a shorthand for all the columns of the selected rows. Also, you can write `table_name.*` as a shorthand for the columns coming from just that table. In these cases it is not possible to specify new names with `AS`; the output column names will be the same as the table columns' names.

According to the SQL standard, the expressions in the output list should be computed before applying `DISTINCT`, `ORDER BY`, or `LIMIT`. This is obviously necessary when using `DISTINCT`, since otherwise it's not clear what values are being made distinct. However, in many cases it is convenient if output expressions are computed after `ORDER BY` and `LIMIT`; particularly if the output list contains any volatile or expensive functions. With that behavior, the order of function evaluations is more intuitive and there will not be evaluations corresponding to rows that never appear in the output. Postgres Pro will effectively evaluate output expressions after sorting and limiting, so long as those expressions are not referenced in `DISTINCT`, `ORDER BY` or `GROUP BY`. (As a counterexample, `SELECT f(x) FROM tab ORDER BY 1`

clearly must evaluate  $f(x)$  before sorting.) Output expressions that contain set-returning functions are effectively evaluated after sorting and before limiting, so that `LIMIT` will act to cut off the output from a set-returning function.

### Note

Postgres Pro versions before 9.6 did not provide any guarantees about the timing of evaluation of output expressions versus sorting and limiting; it depended on the form of the chosen query plan.

## DISTINCT Clause

If `SELECT DISTINCT` is specified, all duplicate rows are removed from the result set (one row is kept from each group of duplicates). `SELECT ALL` specifies the opposite: all rows are kept; that is the default.

`SELECT DISTINCT ON ( expression [, ...] )` keeps only the first row of each set of rows where the given expressions evaluate to equal. The `DISTINCT ON` expressions are interpreted using the same rules as for `ORDER BY` (see above). Note that the “first row” of each set is unpredictable unless `ORDER BY` is used to ensure that the desired row appears first. For example:

```
SELECT DISTINCT ON (location) location, time, report
FROM weather_reports
ORDER BY location, time DESC;
```

retrieves the most recent weather report for each location. But if we had not used `ORDER BY` to force descending order of time values for each location, we'd have gotten a report from an unpredictable time for each location.

The `DISTINCT ON` expression(s) must match the leftmost `ORDER BY` expression(s). The `ORDER BY` clause will normally contain additional expression(s) that determine the desired precedence of rows within each `DISTINCT ON` group.

Currently, `FOR NO KEY UPDATE`, `FOR UPDATE`, `FOR SHARE` and `FOR KEY SHARE` cannot be specified with `DISTINCT`.

## UNION Clause

The `UNION` clause has this general form:

```
select_statement UNION [ ALL | DISTINCT ] select_statement
```

*select\_statement* is any `SELECT` statement without an `ORDER BY`, `LIMIT`, `FOR NO KEY UPDATE`, `FOR UPDATE`, `FOR SHARE`, or `FOR KEY SHARE` clause. (`ORDER BY` and `LIMIT` can be attached to a subexpression if it is enclosed in parentheses. Without parentheses, these clauses will be taken to apply to the result of the `UNION`, not to its right-hand input expression.)

The `UNION` operator computes the set union of the rows returned by the involved `SELECT` statements. A row is in the set union of two result sets if it appears in at least one of the result sets. The two `SELECT` statements that represent the direct operands of the `UNION` must produce the same number of columns, and corresponding columns must be of compatible data types.

The result of `UNION` does not contain any duplicate rows unless the `ALL` option is specified. `ALL` prevents elimination of duplicates. (Therefore, `UNION ALL` is usually significantly quicker than `UNION`; use `ALL` when you can.) `DISTINCT` can be written to explicitly specify the default behavior of eliminating duplicate rows.

Multiple `UNION` operators in the same `SELECT` statement are evaluated left to right, unless otherwise indicated by parentheses.

Currently, `FOR NO KEY UPDATE`, `FOR UPDATE`, `FOR SHARE` and `FOR KEY SHARE` cannot be specified either for a `UNION` result or for any input of a `UNION`.

## INTERSECT Clause

The INTERSECT clause has this general form:

```
select_statement INTERSECT [ ALL | DISTINCT ] select_statement
```

*select\_statement* is any SELECT statement without an ORDER BY, LIMIT, FOR NO KEY UPDATE, FOR UPDATE, FOR SHARE, or FOR KEY SHARE clause.

The INTERSECT operator computes the set intersection of the rows returned by the involved SELECT statements. A row is in the intersection of two result sets if it appears in both result sets.

The result of INTERSECT does not contain any duplicate rows unless the ALL option is specified. With ALL, a row that has  $m$  duplicates in the left table and  $n$  duplicates in the right table will appear  $\min(m,n)$  times in the result set. DISTINCT can be written to explicitly specify the default behavior of eliminating duplicate rows.

Multiple INTERSECT operators in the same SELECT statement are evaluated left to right, unless parentheses dictate otherwise. INTERSECT binds more tightly than UNION. That is, A UNION B INTERSECT C will be read as A UNION (B INTERSECT C).

Currently, FOR NO KEY UPDATE, FOR UPDATE, FOR SHARE and FOR KEY SHARE cannot be specified either for an INTERSECT result or for any input of an INTERSECT.

## EXCEPT Clause

The EXCEPT clause has this general form:

```
select_statement EXCEPT [ ALL | DISTINCT ] select_statement
```

*select\_statement* is any SELECT statement without an ORDER BY, LIMIT, FOR NO KEY UPDATE, FOR UPDATE, FOR SHARE, or FOR KEY SHARE clause.

The EXCEPT operator computes the set of rows that are in the result of the left SELECT statement but not in the result of the right one.

The result of EXCEPT does not contain any duplicate rows unless the ALL option is specified. With ALL, a row that has  $m$  duplicates in the left table and  $n$  duplicates in the right table will appear  $\max(m-n,0)$  times in the result set. DISTINCT can be written to explicitly specify the default behavior of eliminating duplicate rows.

Multiple EXCEPT operators in the same SELECT statement are evaluated left to right, unless parentheses dictate otherwise. EXCEPT binds at the same level as UNION.

Currently, FOR NO KEY UPDATE, FOR UPDATE, FOR SHARE and FOR KEY SHARE cannot be specified either for an EXCEPT result or for any input of an EXCEPT.

## ORDER BY Clause

The optional ORDER BY clause has this general form:

```
ORDER BY expression [ ASC | DESC | USING operator ] [ NULLS { FIRST | LAST } ] [, ...]
```

The ORDER BY clause causes the result rows to be sorted according to the specified expression(s). If two rows are equal according to the leftmost expression, they are compared according to the next expression and so on. If they are equal according to all specified expressions, they are returned in an implementation-dependent order.

Each *expression* can be the name or ordinal number of an output column (SELECT list item), or it can be an arbitrary expression formed from input-column values.

The ordinal number refers to the ordinal (left-to-right) position of the output column. This feature makes it possible to define an ordering on the basis of a column that does not have a unique name. This is

never absolutely necessary because it is always possible to assign a name to an output column using the `AS` clause.

It is also possible to use arbitrary expressions in the `ORDER BY` clause, including columns that do not appear in the `SELECT` output list. Thus the following statement is valid:

```
SELECT name FROM distributors ORDER BY code;
```

A limitation of this feature is that an `ORDER BY` clause applying to the result of a `UNION`, `INTERSECT`, or `EXCEPT` clause can only specify an output column name or number, not an expression.

If an `ORDER BY` expression is a simple name that matches both an output column name and an input column name, `ORDER BY` will interpret it as the output column name. This is the opposite of the choice that `GROUP BY` will make in the same situation. This inconsistency is made to be compatible with the SQL standard.

Optionally one can add the key word `ASC` (ascending) or `DESC` (descending) after any expression in the `ORDER BY` clause. If not specified, `ASC` is assumed by default. Alternatively, a specific ordering operator name can be specified in the `USING` clause. An ordering operator must be a less-than or greater-than member of some B-tree operator family. `ASC` is usually equivalent to `USING <` and `DESC` is usually equivalent to `USING >`. (But the creator of a user-defined data type can define exactly what the default sort ordering is, and it might correspond to operators with other names.)

If `NULLS LAST` is specified, null values sort after all non-null values; if `NULLS FIRST` is specified, null values sort before all non-null values. If neither is specified, the default behavior is `NULLS LAST` when `ASC` is specified or implied, and `NULLS FIRST` when `DESC` is specified (thus, the default is to act as though nulls are larger than non-nulls). When `USING` is specified, the default nulls ordering depends on whether the operator is a less-than or greater-than operator.

Note that ordering options apply only to the expression they follow; for example `ORDER BY x, y DESC` does not mean the same thing as `ORDER BY x DESC, y DESC`.

Character-string data is sorted according to the collation that applies to the column being sorted. That can be overridden at need by including a `COLLATE` clause in the *expression*, for example `ORDER BY mycolumn COLLATE "en_US"`. For more information see [Section 4.2.10](#) and [Section 22.2](#).

## LIMIT Clause

The `LIMIT` clause consists of two independent sub-clauses:

```
LIMIT { count | ALL }
OFFSET start
```

The parameter *count* specifies the maximum number of rows to return, while *start* specifies the number of rows to skip before starting to return rows. When both are specified, *start* rows are skipped before starting to count the *count* rows to be returned.

If the *count* expression evaluates to `NULL`, it is treated as `LIMIT ALL`, i.e., no limit. If *start* evaluates to `NULL`, it is treated the same as `OFFSET 0`.

SQL:2008 introduced a different syntax to achieve the same result, which Postgres Pro also supports. It is:

```
OFFSET start { ROW | ROWS }
FETCH { FIRST | NEXT } [ count ] { ROW | ROWS } { ONLY | WITH TIES }
```

In this syntax, the *start* or *count* value is required by the standard to be a literal constant, a parameter, or a variable name; as a Postgres Pro extension, other expressions are allowed, but will generally need to be enclosed in parentheses to avoid ambiguity. If *count* is omitted in a `FETCH` clause, it defaults to 1. The `WITH TIES` option is used to return any additional rows that tie for the last place in the result set according to the `ORDER BY` clause; `ORDER BY` is mandatory in this case, and `SKIP LOCKED` is not allowed. `ROW` and `ROWS` as well as `FIRST` and `NEXT` are noise words that don't influence the effects of these clauses.

According to the standard, the `OFFSET` clause must come before the `FETCH` clause if both are present; but Postgres Pro is laxer and allows either order.

When using `LIMIT`, it is a good idea to use an `ORDER BY` clause that constrains the result rows into a unique order. Otherwise you will get an unpredictable subset of the query's rows — you might be asking for the tenth through twentieth rows, but tenth through twentieth in what ordering? You don't know what ordering unless you specify `ORDER BY`.

The query planner takes `LIMIT` into account when generating a query plan, so you are very likely to get different plans (yielding different row orders) depending on what you use for `LIMIT` and `OFFSET`. Thus, using different `LIMIT/OFFSET` values to select different subsets of a query result *will give inconsistent results* unless you enforce a predictable result ordering with `ORDER BY`. This is not a bug; it is an inherent consequence of the fact that SQL does not promise to deliver the results of a query in any particular order unless `ORDER BY` is used to constrain the order.

It is even possible for repeated executions of the same `LIMIT` query to return different subsets of the rows of a table, if there is not an `ORDER BY` to enforce selection of a deterministic subset. Again, this is not a bug; determinism of the results is simply not guaranteed in such a case.

## The Locking Clause

`FOR UPDATE`, `FOR NO KEY UPDATE`, `FOR SHARE` and `FOR KEY SHARE` are *locking clauses*; they affect how `SELECT` locks rows as they are obtained from the table.

The locking clause has the general form

```
FOR lock_strength [ OF table_name [, ...] ] [ NOWAIT | SKIP LOCKED ]
```

where *lock\_strength* can be one of

```
UPDATE  
NO KEY UPDATE  
SHARE  
KEY SHARE
```

For more information on each row-level lock mode, refer to [Section 13.3.2](#).

To prevent the operation from waiting for other transactions to commit, use either the `NOWAIT` or `SKIP LOCKED` option. With `NOWAIT`, the statement reports an error, rather than waiting, if a selected row cannot be locked immediately. With `SKIP LOCKED`, any selected rows that cannot be immediately locked are skipped. Skipping locked rows provides an inconsistent view of the data, so this is not suitable for general purpose work, but can be used to avoid lock contention with multiple consumers accessing a queue-like table. Note that `NOWAIT` and `SKIP LOCKED` apply only to the row-level lock(s) — the required `ROW SHARE` table-level lock is still taken in the ordinary way (see [Chapter 13](#)). You can use `LOCK` with the `NOWAIT` option first, if you need to acquire the table-level lock without waiting.

If specific tables are named in a locking clause, then only rows coming from those tables are locked; any other tables used in the `SELECT` are simply read as usual. A locking clause without a table list affects all tables used in the statement. If a locking clause is applied to a view or sub-query, it affects all tables used in the view or sub-query. However, these clauses do not apply to `WITH` queries referenced by the primary query. If you want row locking to occur within a `WITH` query, specify a locking clause within the `WITH` query.

Multiple locking clauses can be written if it is necessary to specify different locking behavior for different tables. If the same table is mentioned (or implicitly affected) by more than one locking clause, then it is processed as if it was only specified by the strongest one. Similarly, a table is processed as `NOWAIT` if that is specified in any of the clauses affecting it. Otherwise, it is processed as `SKIP LOCKED` if that is specified in any of the clauses affecting it.

The locking clauses cannot be used in contexts where returned rows cannot be clearly identified with individual table rows; for example they cannot be used with aggregation.

When a locking clause appears at the top level of a `SELECT` query, the rows that are locked are exactly those that are returned by the query; in the case of a join query, the rows locked are those that contribute to returned join rows. In addition, rows that satisfied the query conditions as of the query snapshot will be locked, although they will not be returned if they were updated after the snapshot and no longer satisfy the query conditions. If a `LIMIT` is used, locking stops once enough rows have been returned to satisfy the limit (but note that rows skipped over by `OFFSET` will get locked). Similarly, if a locking clause is used in a cursor's query, only rows actually fetched or stepped past by the cursor will be locked.

When a locking clause appears in a sub-`SELECT`, the rows locked are those returned to the outer query by the sub-query. This might involve fewer rows than inspection of the sub-query alone would suggest, since conditions from the outer query might be used to optimize execution of the sub-query. For example,

```
SELECT * FROM (SELECT * FROM mytable FOR UPDATE) ss WHERE col1 = 5;
```

will lock only rows having `col1 = 5`, even though that condition is not textually within the sub-query.

Previous releases failed to preserve a lock which is upgraded by a later savepoint. For example, this code:

```
BEGIN;
SELECT * FROM mytable WHERE key = 1 FOR UPDATE;
SAVEPOINT s;
UPDATE mytable SET ... WHERE key = 1;
ROLLBACK TO s;
```

would fail to preserve the `FOR UPDATE` lock after the `ROLLBACK TO`. This has been fixed in release 9.3.

### Caution

It is possible for a `SELECT` command running at the `READ COMMITTED` transaction isolation level and using `ORDER BY` and a locking clause to return rows out of order. This is because `ORDER BY` is applied first. The command sorts the result, but might then block trying to obtain a lock on one or more of the rows. Once the `SELECT` unblocks, some of the ordering column values might have been modified, leading to those rows appearing to be out of order (though they are in order in terms of the original column values). This can be worked around at need by placing the `FOR UPDATE/SHARE` clause in a sub-query, for example

```
SELECT * FROM (SELECT * FROM mytable FOR UPDATE) ss ORDER BY column1;
```

Note that this will result in locking all rows of `mytable`, whereas `FOR UPDATE` at the top level would lock only the actually returned rows. This can make for a significant performance difference, particularly if the `ORDER BY` is combined with `LIMIT` or other restrictions. So this technique is recommended only if concurrent updates of the ordering columns are expected and a strictly sorted result is required.

At the `REPEATABLE READ` or `SERIALIZABLE` transaction isolation level this would cause a serialization failure (with a `SQLSTATE` of '40001'), so there is no possibility of receiving rows out of order under these isolation levels.

### TABLE Command

The command

```
TABLE name
```

is equivalent to

```
SELECT * FROM name
```

It can be used as a top-level command or as a space-saving syntax variant in parts of complex queries. Only the `WITH`, `UNION`, `INTERSECT`, `EXCEPT`, `ORDER BY`, `LIMIT`, `OFFSET`, `FETCH` and `FOR` locking clauses can be used with `TABLE`; the `WHERE` clause and any form of aggregation cannot be used.

## Examples

To join the table `films` with the table `distributors`:

```
SELECT f.title, f.did, d.name, f.date_prod, f.kind
   FROM distributors d, films f
  WHERE f.did = d.did
```

title	did	name	date_prod	kind
The Third Man	101	British Lion	1949-12-23	Drama
The African Queen	101	British Lion	1951-08-11	Romantic
...				

To sum the column `len` of all films and group the results by `kind`:

```
SELECT kind, sum(len) AS total FROM films GROUP BY kind;
```

kind	total
Action	07:34
Comedy	02:58
Drama	14:28
Musical	06:42
Romantic	04:38

To sum the column `len` of all films, group the results by `kind` and show those group totals that are less than 5 hours:

```
SELECT kind, sum(len) AS total
   FROM films
  GROUP BY kind
  HAVING sum(len) < interval '5 hours';
```

kind	total
Comedy	02:58
Romantic	04:38

The following two examples are identical ways of sorting the individual results according to the contents of the second column (`name`):

```
SELECT * FROM distributors ORDER BY name;
SELECT * FROM distributors ORDER BY 2;
```

did	name
109	20th Century Fox
110	Bavaria Atelier
101	British Lion
107	Columbia
102	Jean Luc Godard
113	Luso films
104	Mosfilm
103	Paramount
106	Toho
105	United Artists
111	Walt Disney
112	Warner Bros.
108	Westward

---

## SELECT

---

The next example shows how to obtain the union of the tables `distributors` and `actors`, restricting the results to those that begin with the letter `W` in each table. Only distinct rows are wanted, so the key word `ALL` is omitted.

```
distributors:           actors:
did |      name           id |      name
-----+-----
108 | Westward             1 | Woody Allen
111 | Walt Disney          2 | Warren Beatty
112 | Warner Bros.        3 | Walter Matthau
...                   ...
```

```
SELECT distributors.name
      FROM distributors
      WHERE distributors.name LIKE 'W%'
UNION
SELECT actors.name
      FROM actors
      WHERE actors.name LIKE 'W%';
```

```
      name
-----
Walt Disney
Walter Matthau
Warner Bros.
Warren Beatty
Westward
Woody Allen
```

This example shows how to use a function in the `FROM` clause, both with and without a column definition list:

```
CREATE FUNCTION distributors(int) RETURNS SETOF distributors AS $$
      SELECT * FROM distributors WHERE did = $1;
$$ LANGUAGE SQL;
```

```
SELECT * FROM distributors(111);
did |      name
-----+-----
111 | Walt Disney
```

```
CREATE FUNCTION distributors_2(int) RETURNS SETOF record AS $$
      SELECT * FROM distributors WHERE did = $1;
$$ LANGUAGE SQL;
```

```
SELECT * FROM distributors_2(111) AS (f1 int, f2 text);
f1 |      f2
-----+-----
111 | Walt Disney
```

Here is an example of a function with an ordinality column added:

```
SELECT * FROM unnest(ARRAY['a','b','c','d','e','f']) WITH ORDINALITY;
unnest | ordinality
-----+-----
a      |          1
b      |          2
c      |          3
d      |          4
e      |          5
```

```
f      |      6
(6 rows)
```

This example shows how to use a simple `WITH` clause:

```
WITH t AS (
    SELECT random() as x FROM generate_series(1, 3)
)
SELECT * FROM t
UNION ALL
SELECT * FROM t
```

```
      x
-----
0.534150459803641
0.520092216785997
0.0735620250925422
0.534150459803641
0.520092216785997
0.0735620250925422
```

Notice that the `WITH` query was evaluated only once, so that we got two sets of the same three random values.

This example uses `WITH RECURSIVE` to find all subordinates (direct or indirect) of the employee Mary, and their level of indirectness, from a table that shows only direct subordinates:

```
WITH RECURSIVE employee_recursive(distance, employee_name, manager_name) AS (
    SELECT 1, employee_name, manager_name
    FROM employee
    WHERE manager_name = 'Mary'
    UNION ALL
    SELECT er.distance + 1, e.employee_name, e.manager_name
    FROM employee_recursive er, employee e
    WHERE er.employee_name = e.manager_name
)
SELECT distance, employee_name FROM employee_recursive;
```

Notice the typical form of recursive queries: an initial condition, followed by `UNION`, followed by the recursive part of the query. Be sure that the recursive part of the query will eventually return no tuples, or else the query will loop indefinitely. (See [Section 7.8](#) for more examples.)

This example uses `LATERAL` to apply a set-returning function `get_product_names()` for each row of the `manufacturers` table:

```
SELECT m.name AS mname, pname
FROM manufacturers m, LATERAL get_product_names(m.id) pname;
```

Manufacturers not currently having any products would not appear in the result, since it is an inner join. If we wished to include the names of such manufacturers in the result, we could do:

```
SELECT m.name AS mname, pname
FROM manufacturers m LEFT JOIN LATERAL get_product_names(m.id) pname ON true;
```

## Compatibility

Of course, the `SELECT` statement is compatible with the SQL standard. But there are some extensions and some missing features.

### Omitted `FROM` Clauses

Postgres Pro allows one to omit the `FROM` clause. It has a straightforward use to compute the results of simple expressions:

```
SELECT 2+2;
```

```
?column?
```

```
-----  
4
```

Some other SQL databases cannot do this except by introducing a dummy one-row table from which to do the `SELECT`.

Note that if a `FROM` clause is not specified, the query cannot reference any database tables. For example, the following query is invalid:

```
SELECT distributors.* WHERE distributors.name = 'Westward';
```

PostgreSQL releases prior to 8.1 would accept queries of this form, and add an implicit entry to the query's `FROM` clause for each table referenced by the query. This is no longer allowed.

### Empty `SELECT` Lists

The list of output expressions after `SELECT` can be empty, producing a zero-column result table. This is not valid syntax according to the SQL standard. Postgres Pro allows it to be consistent with allowing zero-column tables. However, an empty list is not allowed when `DISTINCT` is used.

### Omitting the `AS` Key Word

In the SQL standard, the optional key word `AS` can be omitted before an output column name whenever the new column name is a valid column name (that is, not the same as any reserved keyword). Postgres Pro is slightly more restrictive: `AS` is required if the new column name matches any keyword at all, reserved or not. Recommended practice is to use `AS` or double-quote output column names, to prevent any possible conflict against future keyword additions.

In `FROM` items, both the standard and Postgres Pro allow `AS` to be omitted before an alias that is an unreserved keyword. But this is impractical for output column names, because of syntactic ambiguities.

### `ONLY` and Inheritance

The SQL standard requires parentheses around the table name when writing `ONLY`, for example `SELECT * FROM ONLY (tab1), ONLY (tab2) WHERE ...`. Postgres Pro considers these parentheses to be optional.

Postgres Pro allows a trailing `*` to be written to explicitly specify the non-`ONLY` behavior of including child tables. The standard does not allow this.

(These points apply equally to all SQL commands supporting the `ONLY` option.)

### `TABLESAMPLE` Clause Restrictions

The `TABLESAMPLE` clause is currently accepted only on regular tables and materialized views. According to the SQL standard it should be possible to apply it to any `FROM` item.

### Function Calls in `FROM`

Postgres Pro allows a function call to be written directly as a member of the `FROM` list. In the SQL standard it would be necessary to wrap such a function call in a sub-`SELECT`; that is, the syntax `FROM func(...)` *alias* is approximately equivalent to `FROM LATERAL (SELECT func(...)) alias`. Note that `LATERAL` is considered to be implicit; this is because the standard requires `LATERAL` semantics for an `UNNEST()` item in `FROM`. Postgres Pro treats `UNNEST()` the same as other set-returning functions.

### Namespace Available to `GROUP BY` and `ORDER BY`

In the SQL-92 standard, an `ORDER BY` clause can only use output column names or numbers, while a `GROUP BY` clause can only use expressions based on input column names. Postgres Pro extends each of these clauses to allow the other choice as well (but it uses the standard's interpretation if there is ambiguity).

Postgres Pro also allows both clauses to specify arbitrary expressions. Note that names appearing in an expression will always be taken as input-column names, not as output-column names.

SQL:1999 and later use a slightly different definition which is not entirely upward compatible with SQL-92. In most cases, however, Postgres Pro will interpret an `ORDER BY` or `GROUP BY` expression the same way SQL:1999 does.

## Functional Dependencies

Postgres Pro recognizes functional dependency (allowing columns to be omitted from `GROUP BY`) only when a table's primary key is included in the `GROUP BY` list. The SQL standard specifies additional conditions that should be recognized.

## LIMIT and OFFSET

The clauses `LIMIT` and `OFFSET` are Postgres Pro-specific syntax, also used by MySQL. The SQL:2008 standard has introduced the clauses `OFFSET ... FETCH {FIRST|NEXT} ...` for the same functionality, as shown above in [LIMIT Clause](#). This syntax is also used by IBM DB2. (Applications written for Oracle frequently use a workaround involving the automatically generated `rownum` column, which is not available in Postgres Pro, to implement the effects of these clauses.)

## FOR NO KEY UPDATE, FOR UPDATE, FOR SHARE, FOR KEY SHARE

Although `FOR UPDATE` appears in the SQL standard, the standard allows it only as an option of `DECLARE CURSOR`. Postgres Pro allows it in any `SELECT` query as well as in sub-`SELECTs`, but this is an extension. The `FOR NO KEY UPDATE`, `FOR SHARE` and `FOR KEY SHARE` variants, as well as the `NOWAIT` and `SKIP LOCKED` options, do not appear in the standard.

## Data-Modifying Statements in WITH

Postgres Pro allows `INSERT`, `UPDATE`, and `DELETE` to be used as `WITH` queries. This is not found in the SQL standard.

## Nonstandard Clauses

`DISTINCT ON ( ... )` is an extension of the SQL standard.

`ROWS FROM( ... )` is an extension of the SQL standard.

The `MATERIALIZED` and `NOT MATERIALIZED` options of `WITH` are extensions of the SQL standard.

---

## SELECT INTO

SELECT INTO — define a new table from the results of a query

### Synopsis

```
[ WITH [ RECURSIVE ] with_query [, ...] ]
SELECT [ ALL | DISTINCT [ ON ( expression [, ...] ) ] ]

[ FOR { UPDATE | SHARE } [ OF table_name [, ...] ] [ NOWAIT ] [...] ]
```

### Description

SELECT INTO creates a new table and fills it with data computed by a query. The data is not returned to the client, as it is with a normal SELECT. The new table's columns have the names and data types associated with the output columns of the SELECT.

### Parameters

TEMPORARY or TEMP

If specified, the table is created as a temporary table. Refer to [CREATE TABLE](#) for details.

UNLOGGED

If specified, the table is created as an unlogged table. Refer to [CREATE TABLE](#) for details.

*new\_table*

The name (optionally schema-qualified) of the table to be created.

All other parameters are described in detail under [SELECT](#).

### Notes

[CREATE TABLE AS](#) is functionally similar to SELECT INTO. CREATE TABLE AS is the recommended syntax, since this form of SELECT INTO is not available in ECPG or PL/pgSQL, because they interpret the INTO clause differently. Furthermore, CREATE TABLE AS offers a superset of the functionality provided by SELECT INTO.

In contrast to CREATE TABLE AS, SELECT INTO does not allow specifying properties like a table's access method with [USING \*method\*](#) or the table's tablespace with [TABLESPACE \*tablespace\\_name\*](#). Use [CREATE TABLE AS](#) if necessary. Therefore, the default table access method is chosen for the new table. See [default\\_table\\_access\\_method](#) for more information.

### Examples

Create a new table `films_recent` consisting of only recent entries from the table `films`:

```
SELECT * INTO films_recent FROM films WHERE date_prod >= '2002-01-01';
```

### Compatibility

The SQL standard uses `SELECT INTO` to represent selecting values into scalar variables of a host program, rather than creating a new table. This indeed is the usage found in ECPG (see [Chapter 33](#)) and PL/pgSQL (see [Chapter 40](#)). The Postgres Pro usage of `SELECT INTO` to represent table creation is historical. It is best to use `CREATE TABLE AS` for this purpose in new code.

[CREATE TABLE AS](#)

---

# SET

SET — change a run-time parameter

## Synopsis

```
SET [ SESSION | LOCAL ] configuration_parameter { TO | = } { value | 'value' |  
  DEFAULT }  
SET [ SESSION | LOCAL ] TIME ZONE { timezone | LOCAL | DEFAULT }
```

## Description

The `SET` command changes run-time configuration parameters. Many of the run-time parameters listed in [Chapter 18](#) can be changed on-the-fly with `SET`. (But some require superuser privileges to change, and others cannot be changed after server or session start.) `SET` only affects the value used by the current session.

If `SET` (or equivalently `SET SESSION`) is issued within a transaction that is later aborted, the effects of the `SET` command disappear when the transaction is rolled back. Once the surrounding transaction is committed, the effects will persist until the end of the session, unless overridden by another `SET`.

The effects of `SET LOCAL` last only till the end of the current transaction, whether committed or not. A special case is `SET` followed by `SET LOCAL` within a single transaction: the `SET LOCAL` value will be seen until the end of the transaction, but afterwards (if the transaction is committed) the `SET` value will take effect.

The effects of `SET` or `SET LOCAL` are also canceled by rolling back to a savepoint that is earlier than the command.

If `SET LOCAL` is used within a function that has a `SET` option for the same variable (see [CREATE FUNCTION](#)), the effects of the `SET LOCAL` command disappear at function exit; that is, the value in effect when the function was called is restored anyway. This allows `SET LOCAL` to be used for dynamic or repeated changes of a parameter within a function, while still having the convenience of using the `SET` option to save and restore the caller's value. However, a regular `SET` command overrides any surrounding function's `SET` option; its effects will persist unless rolled back.

### Note

In PostgreSQL versions 8.0 through 8.2, the effects of a `SET LOCAL` would be canceled by releasing an earlier savepoint, or by successful exit from a PL/pgSQL exception block. This behavior has been changed because it was deemed unintuitive.

## Parameters

`SESSION`

Specifies that the command takes effect for the current session. (This is the default if neither `SESSION` nor `LOCAL` appears.)

`LOCAL`

Specifies that the command takes effect for only the current transaction. After `COMMIT` or `ROLLBACK`, the session-level setting takes effect again. Issuing this outside of a transaction block emits a warning and otherwise has no effect.

*configuration\_parameter*

Name of a settable run-time parameter. Available parameters are documented in [Chapter 18](#) and below.

*value*

New value of parameter. Values can be specified as string constants, identifiers, numbers, or comma-separated lists of these, as appropriate for the particular parameter. `DEFAULT` can be written to specify resetting the parameter to its default value (that is, whatever value it would have had if no `SET` had been executed in the current session).

Besides the configuration parameters documented in [Chapter 18](#), there are a few that can only be adjusted using the `SET` command or that have a special syntax:

**SCHEMA**

`SET SCHEMA 'value'` is an alias for `SET search_path TO value`. Only one schema can be specified using this syntax.

**NAMES**

`SET NAMES value` is an alias for `SET client_encoding TO value`.

**SEED**

Sets the internal seed for the random number generator (the function `random`). Allowed values are floating-point numbers between -1 and 1, which are then multiplied by  $2^{31}-1$ .

The seed can also be set by invoking the function `setseed`:

```
SELECT setseed(value);
```

**TIME ZONE**

`SET TIME ZONE value` is an alias for `SET timezone TO value`. The syntax `SET TIME ZONE` allows special syntax for the time zone specification. Here are examples of valid values:

`'PST8PDT'`

The time zone for Berkeley, California.

`'Europe/Rome'`

The time zone for Italy.

`-7`

The time zone 7 hours west from UTC (equivalent to PDT). Positive values are east from UTC.

`INTERVAL '-08:00' HOUR TO MINUTE`

The time zone 8 hours west from UTC (equivalent to PST).

`LOCAL`

`DEFAULT`

Set the time zone to your local time zone (that is, the server's default value of `timezone`).

Timezone settings given as numbers or intervals are internally translated to POSIX timezone syntax. For example, after `SET TIME ZONE -7`, `SHOW TIME ZONE` would report `<-07>+07`.

See [Section 8.5.3](#) for more information about time zones.

## Notes

The function `set_config` provides equivalent functionality; see [Section 9.27.1](#). Also, it is possible to `UPDATE` the `pg_settings` system view to perform the equivalent of `SET`.

## Examples

Set the schema search path:

```
SET search_path TO my_schema, public;
```

Set the style of date to traditional POSTGRES with “day before month” input convention:

```
SET datestyle TO postgres, dmy;
```

Set the time zone for Berkeley, California:

```
SET TIME ZONE 'PST8PDT';
```

Set the time zone for Italy:

```
SET TIME ZONE 'Europe/Rome';
```

### Compatibility

`SET TIME ZONE` extends syntax defined in the SQL standard. The standard allows only numeric time zone offsets while Postgres Pro allows more flexible time-zone specifications. All other `SET` features are Postgres Pro extensions.

---

# SET CONSTRAINTS

SET CONSTRAINTS — set constraint check timing for the current transaction

## Synopsis

```
SET CONSTRAINTS { ALL | name [, ...] } { DEFERRED | IMMEDIATE }
```

## Description

SET CONSTRAINTS sets the behavior of constraint checking within the current transaction. IMMEDIATE constraints are checked at the end of each statement. DEFERRED constraints are not checked until transaction commit. Each constraint has its own IMMEDIATE or DEFERRED mode.

Upon creation, a constraint is given one of three characteristics: DEFERRABLE INITIALLY DEFERRED, DEFERRABLE INITIALLY IMMEDIATE, or NOT DEFERRABLE. The third class is always IMMEDIATE and is not affected by the SET CONSTRAINTS command. The first two classes start every transaction in the indicated mode, but their behavior can be changed within a transaction by SET CONSTRAINTS.

SET CONSTRAINTS with a list of constraint names changes the mode of just those constraints (which must all be deferrable). Each constraint name can be schema-qualified. The current schema search path is used to find the first matching name if no schema name is specified. SET CONSTRAINTS ALL changes the mode of all deferrable constraints.

When SET CONSTRAINTS changes the mode of a constraint from DEFERRED to IMMEDIATE, the new mode takes effect retroactively: any outstanding data modifications that would have been checked at the end of the transaction are instead checked during the execution of the SET CONSTRAINTS command. If any such constraint is violated, the SET CONSTRAINTS fails (and does not change the constraint mode). Thus, SET CONSTRAINTS can be used to force checking of constraints to occur at a specific point in a transaction.

Currently, only UNIQUE, PRIMARY KEY, REFERENCES (foreign key), and EXCLUDE constraints are affected by this setting. NOT NULL and CHECK constraints are always checked immediately when a row is inserted or modified (*not* at the end of the statement). Uniqueness and exclusion constraints that have not been declared DEFERRABLE are also checked immediately.

The firing of triggers that are declared as “constraint triggers” is also controlled by this setting — they fire at the same time that the associated constraint should be checked.

## Notes

Because Postgres Pro does not require constraint names to be unique within a schema (but only per-table), it is possible that there is more than one match for a specified constraint name. In this case SET CONSTRAINTS will act on all matches. For a non-schema-qualified name, once a match or matches have been found in some schema in the search path, schemas appearing later in the path are not searched.

This command only alters the behavior of constraints within the current transaction. Issuing this outside of a transaction block emits a warning and otherwise has no effect.

## Compatibility

This command complies with the behavior defined in the SQL standard, except for the limitation that, in Postgres Pro, it does not apply to NOT NULL and CHECK constraints. Also, Postgres Pro checks non-deferrable uniqueness constraints immediately, not at end of statement as the standard would suggest.

---

# SET ROLE

SET ROLE — set the current user identifier of the current session

## Synopsis

```
SET [ SESSION | LOCAL ] ROLE role_name
SET [ SESSION | LOCAL ] ROLE NONE
RESET ROLE
```

## Description

This command sets the current user identifier of the current SQL session to be *role\_name*. The role name can be written as either an identifier or a string literal. After SET ROLE, permissions checking for SQL commands is carried out as though the named role were the one that had logged in originally.

The specified *role\_name* must be a role that the current session user is a member of. (If the session user is a superuser, any role can be selected.)

The SESSION and LOCAL modifiers act the same as for the regular SET command.

SET ROLE NONE sets the current user identifier to the current session user identifier, as returned by session\_user. RESET ROLE sets the current user identifier to the connection-time setting specified by the [command-line options](#), ALTER ROLE, or ALTER DATABASE, if any such settings exist. Otherwise, RESET ROLE sets the current user identifier to the current session user identifier. These forms can be executed by any user.

## Notes

Using this command, it is possible to either add privileges or restrict one's privileges. If the session user role has the INHERIT attribute, then it automatically has all the privileges of every role that it could SET ROLE to; in this case SET ROLE effectively drops all the privileges assigned directly to the session user and to the other roles it is a member of, leaving only the privileges available to the named role. On the other hand, if the session user role has the NOINHERIT attribute, SET ROLE drops the privileges assigned directly to the session user and instead acquires the privileges available to the named role.

In particular, when a superuser chooses to SET ROLE to a non-superuser role, they lose their superuser privileges.

SET ROLE has effects comparable to SET SESSION AUTHORIZATION, but the privilege checks involved are quite different. Also, SET SESSION AUTHORIZATION determines which roles are allowable for later SET ROLE commands, whereas changing roles with SET ROLE does not change the set of roles allowed to a later SET ROLE.

SET ROLE does not process session variables as specified by the role's ALTER ROLE settings; this only happens during login.

SET ROLE cannot be used within a SECURITY DEFINER function.

## Examples

```
SELECT SESSION_USER, CURRENT_USER;

 session_user | current_user
-----+-----
peter        | peter

SET ROLE 'paul';
```

```
SELECT SESSION_USER, CURRENT_USER;
```

```
  session_user | current_user  
-----+-----  
peter         | paul
```

## Compatibility

Postgres Pro allows identifier syntax ("*rolename*"), while the SQL standard requires the role name to be written as a string literal. SQL does not allow this command during a transaction; Postgres Pro does not make this restriction because there is no reason to. The `SESSION` and `LOCAL` modifiers are a Postgres Pro extension, as is the `RESET` syntax.

## See Also

[SET SESSION AUTHORIZATION](#)

---

# SET SESSION AUTHORIZATION

SET SESSION AUTHORIZATION — set the session user identifier and the current user identifier of the current session

## Synopsis

```
SET [ SESSION | LOCAL ] SESSION AUTHORIZATION user_name
SET [ SESSION | LOCAL ] SESSION AUTHORIZATION DEFAULT
RESET SESSION AUTHORIZATION
```

## Description

This command sets the session user identifier and the current user identifier of the current SQL session to be *user\_name*. The user name can be written as either an identifier or a string literal. Using this command, it is possible, for example, to temporarily become an unprivileged user and later switch back to being a superuser.

The session user identifier is initially set to be the (possibly authenticated) user name provided by the client. The current user identifier is normally equal to the session user identifier, but might change temporarily in the context of SECURITY DEFINER functions and similar mechanisms; it can also be changed by [SET ROLE](#). The current user identifier is relevant for permission checking.

The session user identifier can be changed only if the initial session user (the *authenticated user*) had the superuser privilege. Otherwise, the command is accepted only if it specifies the authenticated user name.

The SESSION and LOCAL modifiers act the same as for the regular [SET](#) command.

The DEFAULT and RESET forms reset the session and current user identifiers to be the originally authenticated user name. These forms can be executed by any user.

## Notes

SET SESSION AUTHORIZATION cannot be used within a SECURITY DEFINER function.

## Examples

```
SELECT SESSION_USER, CURRENT_USER;
```

```
 session_user | current_user
-----+-----
peter        | peter
```

```
SET SESSION AUTHORIZATION 'paul';
```

```
SELECT SESSION_USER, CURRENT_USER;
```

```
 session_user | current_user
-----+-----
paul         | paul
```

## Compatibility

The SQL standard allows some other expressions to appear in place of the literal *user\_name*, but these options are not important in practice. Postgres Pro allows identifier syntax ("*username*"), which SQL does not. SQL does not allow this command during a transaction; Postgres Pro does not make this restriction because there is no reason to. The SESSION and LOCAL modifiers are a Postgres Pro extension, as is the RESET syntax.

The privileges necessary to execute this command are left implementation-defined by the standard.

# SET TRANSACTION

SET TRANSACTION — set the characteristics of the current transaction

## Synopsis

```
SET TRANSACTION transaction_mode [, ...]
SET TRANSACTION SNAPSHOT snapshot_id
SET SESSION CHARACTERISTICS AS TRANSACTION transaction_mode [, ...]
```

where *transaction\_mode* is one of:

```
ISOLATION LEVEL { SERIALIZABLE | REPEATABLE READ | READ COMMITTED | READ
UNCOMMITTED }
READ WRITE | READ ONLY
[ NOT ] DEFERRABLE
```

## Description

The `SET TRANSACTION` command sets the characteristics of the current transaction. It has no effect on any subsequent transactions. `SET SESSION CHARACTERISTICS` sets the default transaction characteristics for subsequent transactions of a session. These defaults can be overridden by `SET TRANSACTION` for an individual transaction.

The available transaction characteristics are the transaction isolation level, the transaction access mode (read/write or read-only), and the deferrable mode. In addition, a snapshot can be selected, though only for the current transaction, not as a session default.

The isolation level of a transaction determines what data the transaction can see when other transactions are running concurrently:

`READ COMMITTED`

A statement can only see rows committed before it began. This is the default.

`REPEATABLE READ`

All statements of the current transaction can only see rows committed before the first query or data-modification statement was executed in this transaction.

`SERIALIZABLE`

All statements of the current transaction can only see rows committed before the first query or data-modification statement was executed in this transaction. If a pattern of reads and writes among concurrent serializable transactions would create a situation which could not have occurred for any serial (one-at-a-time) execution of those transactions, one of them will be rolled back with a `serialization_failure` error.

The SQL standard defines one additional level, `READ UNCOMMITTED`. In Postgres Pro `READ UNCOMMITTED` is treated as `READ COMMITTED`.

The transaction isolation level cannot be changed after the first query or data-modification statement (`SELECT`, `INSERT`, `DELETE`, `UPDATE`, `FETCH`, or `COPY`) of a transaction has been executed. See [Chapter 13](#) for more information about transaction isolation and concurrency control.

The transaction access mode determines whether the transaction is read/write or read-only. Read/write is the default. When a transaction is read-only, the following SQL commands are disallowed: `INSERT`, `UPDATE`, `DELETE`, and `COPY FROM` if the table they would write to is not a temporary table; all `CREATE`, `ALTER`, and `DROP` commands; `COMMENT`, `GRANT`, `REVOKE`, `TRUNCATE`; and `EXPLAIN ANALYZE` and `EXECUTE` if the command they would execute is among those listed. This is a high-level notion of read-only that does not prevent all writes to disk.

The `DEFERRABLE` transaction property has no effect unless the transaction is also `SERIALIZABLE` and `READ ONLY`. When all three of these properties are selected for a transaction, the transaction may block when first acquiring its snapshot, after which it is able to run without the normal overhead of a `SERIALIZABLE` transaction and without any risk of contributing to or being canceled by a serialization failure. This mode is well suited for long-running reports or backups.

The `SET TRANSACTION SNAPSHOT` command allows a new transaction to run with the same *snapshot* as an existing transaction. The pre-existing transaction must have exported its snapshot with the `pg_export_snapshot` function (see [Section 9.27.5](#)). That function returns a snapshot identifier, which must be given to `SET TRANSACTION SNAPSHOT` to specify which snapshot is to be imported. The identifier must be written as a string literal in this command, for example `'000003A1-1'`. `SET TRANSACTION SNAPSHOT` can only be executed at the start of a transaction, before the first query or data-modification statement (`SELECT`, `INSERT`, `DELETE`, `UPDATE`, `FETCH`, or `COPY`) of the transaction. Furthermore, the transaction must already be set to `SERIALIZABLE` or `REPEATABLE READ` isolation level (otherwise, the snapshot would be discarded immediately, since `READ COMMITTED` mode takes a new snapshot for each command). If the importing transaction uses `SERIALIZABLE` isolation level, then the transaction that exported the snapshot must also use that isolation level. Also, a non-read-only serializable transaction cannot import a snapshot from a read-only transaction.

## Notes

If `SET TRANSACTION` is executed without a prior `START TRANSACTION` or `BEGIN`, it emits a warning and otherwise has no effect.

It is possible to dispense with `SET TRANSACTION` by instead specifying the desired *transaction\_modes* in `BEGIN` or `START TRANSACTION`. But that option is not available for `SET TRANSACTION SNAPSHOT`.

The session default transaction modes can also be set or examined via the configuration parameters [default\\_transaction\\_isolation](#), [default\\_transaction\\_read\\_only](#), and [default\\_transaction\\_deferrable](#). (In fact `SET SESSION CHARACTERISTICS` is just a verbose equivalent for setting these variables with `SET`.) This means the defaults can be set in the configuration file, via `ALTER DATABASE`, etc. Consult [Chapter 18](#) for more information.

The current transaction's modes can similarly be set or examined via the configuration parameters [transaction\\_isolation](#), [transaction\\_read\\_only](#), and [transaction\\_deferrable](#). Setting one of these parameters acts the same as the corresponding `SET TRANSACTION` option, with the same restrictions on when it can be done. However, these parameters cannot be set in the configuration file, or from any source other than live SQL.

## Examples

To begin a new transaction with the same snapshot as an already existing transaction, first export the snapshot from the existing transaction. That will return the snapshot identifier, for example:

```
BEGIN TRANSACTION ISOLATION LEVEL REPEATABLE READ;
SELECT pg_export_snapshot();
       pg_export_snapshot
-----
00000003-0000001B-1
(1 row)
```

Then give the snapshot identifier in a `SET TRANSACTION SNAPSHOT` command at the beginning of the newly opened transaction:

```
BEGIN TRANSACTION ISOLATION LEVEL REPEATABLE READ;
SET TRANSACTION SNAPSHOT '00000003-0000001B-1';
```

## Compatibility

These commands are defined in the SQL standard, except for the `DEFERRABLE` transaction mode and the `SET TRANSACTION SNAPSHOT` form, which are Postgres Pro extensions.

`SERIALIZABLE` is the default transaction isolation level in the standard. In Postgres Pro the default is ordinarily `READ COMMITTED`, but you can change it as mentioned above.

In the SQL standard, there is one other transaction characteristic that can be set with these commands: the size of the diagnostics area. This concept is specific to embedded SQL, and therefore is not implemented in the Postgres Pro server.

The SQL standard requires commas between successive *transaction\_modes*, but for historical reasons Postgres Pro allows the commas to be omitted.

---

# SHOW

SHOW — show the value of a run-time parameter

## Synopsis

```
SHOW name
SHOW ALL
```

## Description

SHOW will display the current setting of run-time parameters. These variables can be set using the SET statement, by editing the `postgresql.conf` configuration file, through the `PGOPTIONS` environmental variable (when using libpq or a libpq-based application), or through command-line flags when starting the `postgres` server. See [Chapter 18](#) for details.

## Parameters

*name*

The name of a run-time parameter. Available parameters are documented in [Chapter 18](#) and on the [SET](#) reference page. In addition, there are a few parameters that can be shown but not set:

SERVER\_VERSION

Shows the server's version number.

SERVER\_ENCODING

Shows the server-side character set encoding. At present, this parameter can be shown but not set, because the encoding is determined at database creation time.

LC\_COLLATE

Shows the database's locale setting for collation (text ordering). At present, this parameter can be shown but not set, because the setting is determined at database creation time.

LC\_CTYPE

Shows the database's locale setting for character classification. At present, this parameter can be shown but not set, because the setting is determined at database creation time.

IS\_SUPERUSER

True if the current role has superuser privileges.

ALL

Show the values of all configuration parameters, with descriptions.

## Notes

The function `current_setting` produces equivalent output; see [Section 9.27.1](#). Also, the `pg_settings` system view produces the same information.

## Examples

Show the current setting of the parameter `DateStyle`:

```
SHOW DateStyle;
DateStyle
-----
ISO, MDY
```

## SHOW

---

(1 row)

Show the current setting of the parameter `geqo`:

```
SHOW geqo;  
geqo
```

```
-----  
on  
(1 row)
```

Show all settings:

```
SHOW ALL;
```

name	setting	description
allow_system_table_mods	off	Allows modifications of the structure of ...
.	.	.
xmloption	content	Sets whether XML data in implicit parsing ...
zero_damaged_pages	off	Continues processing past damaged page headers.

(196 rows)

## Compatibility

The `SHOW` command is a Postgres Pro extension.

## See Also

[SET](#), [RESET](#)

---

# START TRANSACTION

START TRANSACTION — start a transaction block

## Synopsis

```
START TRANSACTION [ transaction_mode [, ...] ]
```

where *transaction\_mode* is one of:

```
ISOLATION LEVEL { SERIALIZABLE | REPEATABLE READ | READ COMMITTED | READ  
UNCOMMITTED }  
READ WRITE | READ ONLY  
[ NOT ] DEFERRABLE
```

## Description

This command begins a new transaction block. If the isolation level, read/write mode, or deferrable mode is specified, the new transaction has those characteristics, as if [SET TRANSACTION](#) was executed. This is the same as the [BEGIN](#) command.

## Parameters

Refer to [SET TRANSACTION](#) for information on the meaning of the parameters to this statement.

## Compatibility

In the standard, it is not necessary to issue `START TRANSACTION` to start a transaction block: any SQL command implicitly begins a block. Postgres Pro's behavior can be seen as implicitly issuing a `COMMIT` after each command that does not follow `START TRANSACTION` (or `BEGIN`), and it is therefore often called “autocommit”. Other relational database systems might offer an autocommit feature as a convenience.

The `DEFERRABLE transaction_mode` is a Postgres Pro language extension.

The SQL standard requires commas between successive *transaction\_modes*, but for historical reasons Postgres Pro allows the commas to be omitted.

See also the compatibility section of [SET TRANSACTION](#).

## See Also

[BEGIN](#), [COMMIT](#), [ROLLBACK](#), [SAVEPOINT](#), [SET TRANSACTION](#)

---

# TRUNCATE

TRUNCATE — empty a table or set of tables

## Synopsis

```
TRUNCATE [ TABLE ] [ ONLY ] name [ * ] [, ... ]  
        [ RESTART IDENTITY | CONTINUE IDENTITY ] [ CASCADE | RESTRICT ]
```

## Description

TRUNCATE quickly removes all rows from a set of tables. It has the same effect as an unqualified DELETE on each table, but since it does not actually scan the tables it is faster. Furthermore, it reclaims disk space immediately, rather than requiring a subsequent VACUUM operation. This is most useful on large tables.

## Parameters

*name*

The name (optionally schema-qualified) of a table to truncate. If ONLY is specified before the table name, only that table is truncated. If ONLY is not specified, the table and all its descendant tables (if any) are truncated. Optionally, \* can be specified after the table name to explicitly indicate that descendant tables are included.

RESTART IDENTITY

Automatically restart sequences owned by columns of the truncated table(s).

CONTINUE IDENTITY

Do not change the values of sequences. This is the default.

CASCADE

Automatically truncate all tables that have foreign-key references to any of the named tables, or to any tables added to the group due to CASCADE.

RESTRICT

Refuse to truncate if any of the tables have foreign-key references from tables that are not listed in the command. This is the default.

## Notes

You must have the TRUNCATE privilege on a table to truncate it.

TRUNCATE acquires an ACCESS EXCLUSIVE lock on each table it operates on, which blocks all other concurrent operations on the table. When RESTART IDENTITY is specified, any sequences that are to be restarted are likewise locked exclusively. If concurrent access to a table is required, then the DELETE command should be used instead.

TRUNCATE cannot be used on a table that has foreign-key references from other tables, unless all such tables are also truncated in the same command. Checking validity in such cases would require table scans, and the whole point is not to do one. The CASCADE option can be used to automatically include all dependent tables — but be very careful when using this option, or else you might lose data you did not intend to! Note in particular that when the table to be truncated is a partition, siblings partitions are left untouched, but cascading occurs to all referencing tables and all their partitions with no distinction.

TRUNCATE will not fire any ON DELETE triggers that might exist for the tables. But it will fire ON TRUNCATE triggers. If ON TRUNCATE triggers are defined for any of the tables, then all BEFORE TRUNCATE triggers are

fired before any truncation happens, and all `AFTER TRUNCATE` triggers are fired after the last truncation is performed and any sequences are reset. The triggers will fire in the order that the tables are to be processed (first those listed in the command, and then any that were added due to cascading).

`TRUNCATE` is not MVCC-safe. After truncation, the table will appear empty to concurrent transactions, if they are using a snapshot taken before the truncation occurred. See [Section 13.5](#) for more details.

`TRUNCATE` is transaction-safe with respect to the data in the tables: the truncation will be safely rolled back if the surrounding transaction does not commit.

When `RESTART IDENTITY` is specified, the implied `ALTER SEQUENCE RESTART` operations are also done transactionally; that is, they will be rolled back if the surrounding transaction does not commit. Be aware that if any additional sequence operations are done on the restarted sequences before the transaction rolls back, the effects of these operations on the sequences will be rolled back, but not their effects on `currval()`; that is, after the transaction `currval()` will continue to reflect the last sequence value obtained inside the failed transaction, even though the sequence itself may no longer be consistent with that. This is similar to the usual behavior of `currval()` after a failed transaction.

`TRUNCATE` is not currently supported for foreign tables. This implies that if a specified table has any descendant tables that are foreign, the command will fail.

## Examples

Truncate the tables `bigtable` and `fattable`:

```
TRUNCATE bigtable, fattable;
```

The same, and also reset any associated sequence generators:

```
TRUNCATE bigtable, fattable RESTART IDENTITY;
```

Truncate the table `othertable`, and cascade to any tables that reference `othertable` via foreign-key constraints:

```
TRUNCATE othertable CASCADE;
```

## Compatibility

The SQL:2008 standard includes a `TRUNCATE` command with the syntax `TRUNCATE TABLE tablename`. The clauses `CONTINUE IDENTITY/RESTART IDENTITY` also appear in that standard, but have slightly different though related meanings. Some of the concurrency behavior of this command is left implementation-defined by the standard, so the above notes should be considered and compared with other implementations if necessary.

## See Also

[DELETE](#)

---

# UNLISTEN

UNLISTEN — stop listening for a notification

## Synopsis

```
UNLISTEN { channel | * }
```

## Description

UNLISTEN is used to remove an existing registration for NOTIFY events. UNLISTEN cancels any existing registration of the current Postgres Pro session as a listener on the notification channel named *channel*. The special wildcard \* cancels all listener registrations for the current session.

[NOTIFY](#) contains a more extensive discussion of the use of LISTEN and NOTIFY.

## Parameters

*channel*

Name of a notification channel (any identifier).

\*

All current listen registrations for this session are cleared.

## Notes

You can unlisten something you were not listening for; no warning or error will appear.

At the end of each session, UNLISTEN \* is automatically executed.

A transaction that has executed UNLISTEN cannot be prepared for two-phase commit.

## Examples

To make a registration:

```
LISTEN virtual;
NOTIFY virtual;
Asynchronous notification "virtual" received from server process with PID 8448.
```

Once UNLISTEN has been executed, further NOTIFY messages will be ignored:

```
UNLISTEN virtual;
NOTIFY virtual;
-- no NOTIFY event is received
```

## Compatibility

There is no UNLISTEN command in the SQL standard.

# UPDATE

UPDATE — update rows of a table

## Synopsis

```
[ WITH [ RECURSIVE ] with_query [, ...] ]
UPDATE [ ONLY ] table_name [ * ] [ [ AS ] alias ]
    SET { column_name = { expression | DEFAULT } |
        ( column_name [, ...] ) = [ ROW ] ( { expression | DEFAULT } [, ...] ) |
        ( column_name [, ...] ) = ( sub-SELECT )
    } [, ...]
[ FROM from_item [, ...] ]
[ WHERE condition | WHERE CURRENT OF cursor_name ]
[ RETURNING * | output_expression [ [ AS ] output_name ] [, ...] ]
```

## Description

UPDATE changes the values of the specified columns in all rows that satisfy the condition. Only the columns to be modified need be mentioned in the SET clause; columns not explicitly modified retain their previous values.

There are two ways to modify a table using information contained in other tables in the database: using sub-selects, or specifying additional tables in the FROM clause. Which technique is more appropriate depends on the specific circumstances.

The optional RETURNING clause causes UPDATE to compute and return value(s) based on each row actually updated. Any expression using the table's columns, and/or columns of other tables mentioned in FROM, can be computed. The new (post-update) values of the table's columns are used. The syntax of the RETURNING list is identical to that of the output list of SELECT.

You must have the UPDATE privilege on the table, or at least on the column(s) that are listed to be updated. You must also have the SELECT privilege on any column whose values are read in the *expressions* or *condition*.

## Parameters

*with\_query*

The WITH clause allows you to specify one or more subqueries that can be referenced by name in the UPDATE query. See [Section 7.8](#) and [SELECT](#) for details.

*table\_name*

The name (optionally schema-qualified) of the table to update. If ONLY is specified before the table name, matching rows are updated in the named table only. If ONLY is not specified, matching rows are also updated in any tables inheriting from the named table. Optionally, \* can be specified after the table name to explicitly indicate that descendant tables are included.

*alias*

A substitute name for the target table. When an alias is provided, it completely hides the actual name of the table. For example, given UPDATE foo AS f, the remainder of the UPDATE statement must refer to this table as f not foo.

*column\_name*

The name of a column in the table named by *table\_name*. The column name can be qualified with a subfield name or array subscript, if needed. Do not include the table's name in the specification of a target column — for example, UPDATE *table\_name* SET *table\_name.col* = 1 is invalid.

*expression*

An expression to assign to the column. The expression can use the old values of this and other columns in the table.

## DEFAULT

Set the column to its default value (which will be NULL if no specific default expression has been assigned to it). An identity column will be set to a new value generated by the associated sequence. For a generated column, specifying this is permitted but merely specifies the normal behavior of computing the column from its generation expression.

*sub-SELECT*

A SELECT sub-query that produces as many output columns as are listed in the parenthesized column list preceding it. The sub-query must yield no more than one row when executed. If it yields one row, its column values are assigned to the target columns; if it yields no rows, NULL values are assigned to the target columns. The sub-query can refer to old values of the current row of the table being updated.

*from\_item*

A table expression allowing columns from other tables to appear in the WHERE condition and update expressions. This uses the same syntax as the FROM clause of a SELECT statement; for example, an alias for the table name can be specified. Do not repeat the target table as a *from\_item* unless you intend a self-join (in which case it must appear with an alias in the *from\_item*).

*condition*

An expression that returns a value of type `boolean`. Only rows for which this expression returns `true` will be updated.

*cursor\_name*

The name of the cursor to use in a WHERE CURRENT OF condition. The row to be updated is the one most recently fetched from this cursor. The cursor must be a non-grouping query on the UPDATE's target table. Note that WHERE CURRENT OF cannot be specified together with a Boolean condition. See [DECLARE](#) for more information about using cursors with WHERE CURRENT OF.

*output\_expression*

An expression to be computed and returned by the UPDATE command after each row is updated. The expression can use any column names of the table named by *table\_name* or table(s) listed in FROM. Write \* to return all columns.

*output\_name*

A name to use for a returned column.

## Outputs

On successful completion, an UPDATE command returns a command tag of the form

```
UPDATE count
```

The *count* is the number of rows updated, including matched rows whose values did not change. Note that the number may be less than the number of rows that matched the *condition* when updates were suppressed by a BEFORE UPDATE trigger. If *count* is 0, no rows were updated by the query (this is not considered an error).

If the UPDATE command contains a RETURNING clause, the result will be similar to that of a SELECT statement containing the columns and values defined in the RETURNING list, computed over the row(s) updated by the command.

## Notes

When a `FROM` clause is present, what essentially happens is that the target table is joined to the tables mentioned in the `from_item` list, and each output row of the join represents an update operation for the target table. When using `FROM` you should ensure that the join produces at most one output row for each row to be modified. In other words, a target row shouldn't join to more than one row from the other table(s). If it does, then only one of the join rows will be used to update the target row, but which one will be used is not readily predictable.

Because of this indeterminacy, referencing other tables only within sub-selects is safer, though often harder to read and slower than using a join.

In the case of a partitioned table, updating a row might cause it to no longer satisfy the partition constraint of the containing partition. In that case, if there is some other partition in the partition tree for which this row satisfies its partition constraint, then the row is moved to that partition. If there is no such partition, an error will occur. Behind the scenes, the row movement is actually a `DELETE` and `INSERT` operation.

There is a possibility that a concurrent `UPDATE` or `DELETE` on the row being moved will get a serialization failure error. Suppose session 1 is performing an `UPDATE` on a partition key, and meanwhile a concurrent session 2 for which this row is visible performs an `UPDATE` or `DELETE` operation on this row. In such case, session 2's `UPDATE` or `DELETE` will detect the row movement and raise a serialization failure error (which always returns with an `SQLSTATE` code '40001'). Applications may wish to retry the transaction if this occurs. In the usual case where the table is not partitioned, or where there is no row movement, session 2 would have identified the newly updated row and carried out the `UPDATE/DELETE` on this new row version.

Note that while rows can be moved from local partitions to a foreign-table partition (provided the foreign data wrapper supports tuple routing), they cannot be moved from a foreign-table partition to another partition.

## Examples

Change the word `Drama` to `Dramatic` in the column `kind` of the table `films`:

```
UPDATE films SET kind = 'Dramatic' WHERE kind = 'Drama';
```

Adjust temperature entries and reset precipitation to its default value in one row of the table `weather`:

```
UPDATE weather SET temp_lo = temp_lo+1, temp_hi = temp_lo+15, prcp = DEFAULT
  WHERE city = 'San Francisco' AND date = '2003-07-03';
```

Perform the same operation and return the updated entries:

```
UPDATE weather SET temp_lo = temp_lo+1, temp_hi = temp_lo+15, prcp = DEFAULT
  WHERE city = 'San Francisco' AND date = '2003-07-03'
  RETURNING temp_lo, temp_hi, prcp;
```

Use the alternative column-list syntax to do the same update:

```
UPDATE weather SET (temp_lo, temp_hi, prcp) = (temp_lo+1, temp_lo+15, DEFAULT)
  WHERE city = 'San Francisco' AND date = '2003-07-03';
```

Increment the sales count of the salesperson who manages the account for Acme Corporation, using the `FROM` clause syntax:

```
UPDATE employees SET sales_count = sales_count + 1 FROM accounts
  WHERE accounts.name = 'Acme Corporation'
  AND employees.id = accounts.sales_person;
```

Perform the same operation, using a sub-select in the `WHERE` clause:

```
UPDATE employees SET sales_count = sales_count + 1 WHERE id =
  (SELECT sales_person FROM accounts WHERE name = 'Acme Corporation');
```

Update contact names in an accounts table to match the currently assigned salesmen:

```
UPDATE accounts SET (contact_first_name, contact_last_name) =
    (SELECT first_name, last_name FROM salesmen
     WHERE salesmen.id = accounts.sales_id);
```

A similar result could be accomplished with a join:

```
UPDATE accounts SET contact_first_name = first_name,
    contact_last_name = last_name
FROM salesmen WHERE salesmen.id = accounts.sales_id;
```

However, the second query may give unexpected results if `salesmen.id` is not a unique key, whereas the first query is guaranteed to raise an error if there are multiple `id` matches. Also, if there is no match for a particular `accounts.sales_id` entry, the first query will set the corresponding name fields to `NULL`, whereas the second query will not update that row at all.

Update statistics in a summary table to match the current data:

```
UPDATE summary s SET (sum_x, sum_y, avg_x, avg_y) =
    (SELECT sum(x), sum(y), avg(x), avg(y) FROM data d
     WHERE d.group_id = s.group_id);
```

Attempt to insert a new stock item along with the quantity of stock. If the item already exists, instead update the stock count of the existing item. To do this without failing the entire transaction, use savepoints:

```
BEGIN;
-- other operations
SAVEPOINT sp1;
INSERT INTO wines VALUES('Chateau Lafite 2003', '24');
-- Assume the above fails because of a unique key violation,
-- so now we issue these commands:
ROLLBACK TO sp1;
UPDATE wines SET stock = stock + 24 WHERE winename = 'Chateau Lafite 2003';
-- continue with other operations, and eventually
COMMIT;
```

Change the `kind` column of the table `films` in the row on which the cursor `c_films` is currently positioned:

```
UPDATE films SET kind = 'Dramatic' WHERE CURRENT OF c_films;
```

## Compatibility

This command conforms to the SQL standard, except that the `FROM` and `RETURNING` clauses are Postgres Pro extensions, as is the ability to use `WITH` with `UPDATE`.

Some other database systems offer a `FROM` option in which the target table is supposed to be listed again within `FROM`. That is not how Postgres Pro interprets `FROM`. Be careful when porting applications that use this extension.

According to the standard, the source value for a parenthesized sub-list of target column names can be any row-valued expression yielding the correct number of columns. Postgres Pro only allows the source value to be a [row constructor](#) or a sub-`SELECT`. An individual column's updated value can be specified as `DEFAULT` in the row-constructor case, but not inside a sub-`SELECT`.

---

# VACUUM

VACUUM — garbage-collect and optionally analyze a database

## Synopsis

```
VACUUM [ ( option [, ...] ) ] [ table_and_columns [, ...] ]  
VACUUM [ FULL ] [ FREEZE ] [ VERBOSE ] [ ANALYZE ] [ table_and_columns [, ...] ]
```

where *option* can be one of:

```
FULL [ boolean ]  
FREEZE [ boolean ]  
VERBOSE [ boolean ]  
ANALYZE [ boolean ]  
DISABLE_PAGE_SKIPPING [ boolean ]  
SKIP_LOCKED [ boolean ]  
INDEX_CLEANUP [ boolean ]  
TRUNCATE [ boolean ]  
PARALLEL integer
```

and *table\_and\_columns* is:

```
table_name [ ( column_name [, ...] ) ]
```

## Description

VACUUM reclaims storage occupied by dead tuples. In normal Postgres Pro operation, tuples that are deleted or obsoleted by an update are not physically removed from their table; they remain present until a VACUUM is done. Therefore it's necessary to do VACUUM periodically, especially on frequently-updated tables.

Without a *table\_and\_columns* list, VACUUM processes every table and materialized view in the current database that the current user has permission to vacuum. With a list, VACUUM processes only those table(s).

VACUUM ANALYZE performs a VACUUM and then an ANALYZE for each selected table. This is a handy combination form for routine maintenance scripts. See [ANALYZE](#) for more details about its processing.

Plain VACUUM (without FULL) simply reclaims space and makes it available for re-use. This form of the command can operate in parallel with normal reading and writing of the table, as an exclusive lock is not obtained. However, extra space is not returned to the operating system (in most cases); it's just kept available for re-use within the same table. It also allows us to leverage multiple CPUs in order to process indexes. This feature is known as *parallel vacuum*. To disable this feature, one can use PARALLEL option and specify parallel workers as zero. VACUUM FULL rewrites the entire contents of the table into a new disk file with no extra space, allowing unused space to be returned to the operating system. This form is much slower and requires an ACCESS EXCLUSIVE lock on each table while it is being processed.

When the option list is surrounded by parentheses, the options can be written in any order. Without parentheses, options must be specified in exactly the order shown above. The parenthesized syntax was added in PostgreSQL 9.0; the unparenthesized syntax is deprecated.

## Parameters

FULL

Selects “full” vacuum, which can reclaim more space, but takes much longer and exclusively locks the table. This method also requires extra disk space, since it writes a new copy of the table and

doesn't release the old copy until the operation is complete. Usually this should only be used when a significant amount of space needs to be reclaimed from within the table.

**FREEZE**

Selects aggressive “freezing” of tuples. Specifying `FREEZE` is equivalent to performing `VACUUM` with the `vacuum_freeze_min_age` and `vacuum_freeze_table_age` parameters set to zero. Aggressive freezing is always performed when the table is rewritten, so this option is redundant when `FULL` is specified.

**VERBOSE**

Prints a detailed vacuum activity report for each table.

**ANALYZE**

Updates statistics used by the planner to determine the most efficient way to execute a query.

**DISABLE\_PAGE\_SKIPPING**

Normally, `VACUUM` will skip pages based on the [visibility map](#). Pages where all tuples are known to be frozen can always be skipped, and those where all tuples are known to be visible to all transactions may be skipped except when performing an aggressive vacuum. Furthermore, except when performing an aggressive vacuum, some pages may be skipped in order to avoid waiting for other sessions to finish using them. This option disables all page-skipping behavior, and is intended to be used only when the contents of the visibility map are suspect, which should happen only if there is a hardware or software issue causing database corruption.

**SKIP\_LOCKED**

Specifies that `VACUUM` should not wait for any conflicting locks to be released when beginning work on a relation: if a relation cannot be locked immediately without waiting, the relation is skipped. Note that even with this option, `VACUUM` may still block when opening the relation's indexes. Additionally, `VACUUM ANALYZE` may still block when acquiring sample rows from partitions, table inheritance children, and some types of foreign tables. Also, while `VACUUM` ordinarily processes all partitions of specified partitioned tables, this option will cause `VACUUM` to skip all partitions if there is a conflicting lock on the partitioned table.

**INDEX\_CLEANUP**

Specifies that `VACUUM` should attempt to remove index entries pointing to dead tuples. This is normally the desired behavior and is the default unless the `vacuum_index_cleanup` option has been set to false for the table to be vacuumed. Setting this option to false may be useful when it is necessary to make vacuum run as quickly as possible, for example to avoid imminent transaction ID wraparound (see [Section 23.1.5](#)). However, if index cleanup is not performed regularly, performance may suffer, because as the table is modified, indexes will accumulate dead tuples and the table itself will accumulate dead line pointers that cannot be removed until index cleanup is completed. This option has no effect for tables that do not have an index and is ignored if the `FULL` option is used.

**TRUNCATE**

Specifies that `VACUUM` should attempt to truncate off any empty pages at the end of the table and allow the disk space for the truncated pages to be returned to the operating system. This is normally the desired behavior and is the default unless the `vacuum_truncate` option has been set to false for the table to be vacuumed. Setting this option to false may be useful to avoid `ACCESS EXCLUSIVE` lock on the table that the truncation requires. This option is ignored if the `FULL` option is used.

**PARALLEL**

Perform index vacuum and index cleanup phases of `VACUUM` in parallel using *integer* background workers (for the details of each vacuum phase, please refer to [Table 26.37](#)). The number of workers used to perform the operation is equal to the number of indexes on the relation that support parallel vacuum which is limited by the number of workers specified with `PARALLEL` option if any which is

further limited by [max\\_parallel\\_maintenance\\_workers](#). An index can participate in parallel vacuum if and only if the size of the index is more than [min\\_parallel\\_index\\_scan\\_size](#). Please note that it is not guaranteed that the number of parallel workers specified in *integer* will be used during execution. It is possible for a vacuum to run with fewer workers than specified, or even with no workers at all. Only one worker can be used per index. So parallel workers are launched only when there are at least 2 indexes in the table. Workers for vacuum are launched before the start of each phase and exit at the end of the phase. These behaviors might change in a future release. This option can't be used with the `FULL` option.

*boolean*

Specifies whether the selected option should be turned on or off. You can write `TRUE`, `ON`, or `1` to enable the option, and `FALSE`, `OFF`, or `0` to disable it. The *boolean* value can also be omitted, in which case `TRUE` is assumed.

*integer*

Specifies a non-negative integer value passed to the selected option.

*table\_name*

The name (optionally schema-qualified) of a specific table or materialized view to vacuum. If the specified table is a partitioned table, all of its leaf partitions are vacuumed.

*column\_name*

The name of a specific column to analyze. Defaults to all columns. If a column list is specified, `ANALYZE` must also be specified.

## Outputs

When `VERBOSE` is specified, `VACUUM` emits progress messages to indicate which table is currently being processed. Various statistics about the tables are printed as well.

## Notes

To vacuum a table, one must ordinarily be the table's owner or a superuser. However, database owners are allowed to vacuum all tables in their databases, except shared catalogs. (The restriction for shared catalogs means that a true database-wide `VACUUM` can only be performed by a superuser.) `VACUUM` will skip over any tables that the calling user does not have permission to vacuum.

`VACUUM` cannot be executed inside a transaction block.

For tables with GIN indexes, `VACUUM` (in any form) also completes any pending index insertions, by moving pending index entries to the appropriate places in the main GIN index structure. See [Section 62.4.1](#) for details.

We recommend that active production databases be vacuumed frequently (at least nightly), in order to remove dead rows. After adding or deleting a large number of rows, it might be a good idea to issue a `VACUUM ANALYZE` command for the affected table. This will update the system catalogs with the results of all recent changes, and allow the Postgres Pro query planner to make better choices in planning queries.

The `FULL` option is not recommended for routine use, but might be useful in special cases. An example is when you have deleted or updated most of the rows in a table and would like the table to physically shrink to occupy less disk space and allow faster table scans. `VACUUM FULL` will usually shrink the table more than a plain `VACUUM` would.

The `PARALLEL` option is used only for vacuum purposes. If this option is specified with the `ANALYZE` option, it does not affect `ANALYZE`.

`VACUUM` causes a substantial increase in I/O traffic, which might cause poor performance for other active sessions. Therefore, it is sometimes advisable to use the cost-based vacuum delay feature. For parallel vacuum, each worker sleeps in proportion to the work done by that worker. See [Section 18.4.4](#) for details.

Postgres Pro includes an “autovacuum” facility which can automate routine vacuum maintenance. For more information about automatic and manual vacuuming, see [Section 23.1](#).

### Examples

To clean a single table `onek`, analyze it for the optimizer and print a detailed vacuum activity report:

```
VACUUM (VERBOSE, ANALYZE) onek;
```

### Compatibility

There is no `VACUUM` statement in the SQL standard.

[vacuumdb](#), [Section 18.4.4](#), [Section 23.1.6](#)

---

# VALUES

VALUES — compute a set of rows

## Synopsis

```
VALUES ( expression [, ...] ) [, ...]  
  [ ORDER BY sort_expression [ ASC | DESC | USING operator ] [, ...] ]  
  [ LIMIT { count | ALL } ]  
  [ OFFSET start [ ROW | ROWS ] ]  
  [ FETCH { FIRST | NEXT } [ count ] { ROW | ROWS } ONLY ]
```

## Description

VALUES computes a row value or set of row values specified by value expressions. It is most commonly used to generate a “constant table” within a larger command, but it can be used on its own.

When more than one row is specified, all the rows must have the same number of elements. The data types of the resulting table's columns are determined by combining the explicit or inferred types of the expressions appearing in that column, using the same rules as for UNION (see [Section 10.5](#)).

Within larger commands, VALUES is syntactically allowed anywhere that SELECT is. Because it is treated like a SELECT by the grammar, it is possible to use the ORDER BY, LIMIT (or equivalently FETCH FIRST), and OFFSET clauses with a VALUES command.

## Parameters

*expression*

A constant or expression to compute and insert at the indicated place in the resulting table (set of rows). In a VALUES list appearing at the top level of an INSERT, an *expression* can be replaced by DEFAULT to indicate that the destination column's default value should be inserted. DEFAULT cannot be used when VALUES appears in other contexts.

*sort\_expression*

An expression or integer constant indicating how to sort the result rows. This expression can refer to the columns of the VALUES result as column1, column2, etc. For more details see [ORDER BY Clause](#) in the [SELECT](#) documentation.

*operator*

A sorting operator. For details see [ORDER BY Clause](#) in the [SELECT](#) documentation.

*count*

The maximum number of rows to return. For details see [LIMIT Clause](#) in the [SELECT](#) documentation.

*start*

The number of rows to skip before starting to return rows. For details see [LIMIT Clause](#) in the [SELECT](#) documentation.

## Notes

VALUES lists with very large numbers of rows should be avoided, as you might encounter out-of-memory failures or poor performance. VALUES appearing within INSERT is a special case (because the desired column types are known from the INSERT's target table, and need not be inferred by scanning the VALUES list), so it can handle larger lists than are practical in other contexts.

## Examples

A bare VALUES command:

```
VALUES (1, 'one'), (2, 'two'), (3, 'three');
```

This will return a table of two columns and three rows. It's effectively equivalent to:

```
SELECT 1 AS column1, 'one' AS column2
UNION ALL
SELECT 2, 'two'
UNION ALL
SELECT 3, 'three';
```

More usually, VALUES is used within a larger SQL command. The most common use is in INSERT:

```
INSERT INTO films (code, title, did, date_prod, kind)
VALUES ('T_601', 'Yojimbo', 106, '1961-06-16', 'Drama');
```

In the context of INSERT, entries of a VALUES list can be DEFAULT to indicate that the column default should be used here instead of specifying a value:

```
INSERT INTO films VALUES
('UA502', 'Bananas', 105, DEFAULT, 'Comedy', '82 minutes'),
('T_601', 'Yojimbo', 106, DEFAULT, 'Drama', DEFAULT);
```

VALUES can also be used where a sub-SELECT might be written, for example in a FROM clause:

```
SELECT f.*
FROM films f, (VALUES('MGM', 'Horror'), ('UA', 'Sci-Fi')) AS t (studio, kind)
WHERE f.studio = t.studio AND f.kind = t.kind;
```

```
UPDATE employees SET salary = salary * v.increase
FROM (VALUES(1, 200000, 1.2), (2, 400000, 1.4)) AS v (deпно, target, increase)
WHERE employees.deпно = v.deпно AND employees.sales >= v.target;
```

Note that an AS clause is required when VALUES is used in a FROM clause, just as is true for SELECT. It is not required that the AS clause specify names for all the columns, but it's good practice to do so. (The default column names for VALUES are column1, column2, etc in Postgres Pro, but these names might be different in other database systems.)

When VALUES is used in INSERT, the values are all automatically coerced to the data type of the corresponding destination column. When it's used in other contexts, it might be necessary to specify the correct data type. If the entries are all quoted literal constants, coercing the first is sufficient to determine the assumed type for all:

```
SELECT * FROM machines
WHERE ip_address IN (VALUES('192.168.0.1'::inet), ('192.168.0.10'), ('192.168.1.43'));
```

### Tip

For simple IN tests, it's better to rely on the [list-of-scalars](#) form of IN than to write a VALUES query as shown above. The list of scalars method requires less writing and is often more efficient.

## Compatibility

VALUES conforms to the SQL standard. LIMIT and OFFSET are Postgres Pro extensions; see also under [SELECT](#).

[INSERT](#), [SELECT](#)

---

# WAITLSN

WAITLSN — wait for the target LSN to be replayed

## Synopsis

```
WAITLSN 'LSN' [ INFINITELY ]
WAITLSN 'LSN' TIMEOUT wait_time
WAITLSN 'LSN' NOWAIT
```

## Description

WAITLSN provides a simple interprocess communication mechanism to wait for the target log sequence number (LSN) on standby in Postgres Pro databases with master-standby asynchronous replication. When run with the *LSN* option, the WAITLSN command waits for the specified LSN to be replayed. By default, wait time is unlimited. Waiting can be interrupted using `Ctrl+C`, or by shutting down the `postgres` server. You can also limit the wait time using the `TIMEOUT` option, or check the target LSN status immediately using the `NOWAIT` option.

### Important

The WAITLSN command is deprecated.

## Parameters

*LSN*

Specify the target log sequence number to wait for.

INFINITELY

Wait until the target LSN is replayed on standby. This is an optional parameter reinforcing the default behavior.

TIMEOUT *wait\_time*

Limit the time to wait for the LSN to be replayed. The specified *wait\_time* must be an integer and is measured in milliseconds.

NOWAIT

Report whether the target LSN has been replayed already, without any waiting.

## Examples

Run WAITLSN from `psql`, limiting wait time to 10000 milliseconds:

```
WAITLSN '0/3F07A6B1' TIMEOUT 10000;
NOTICE: LSN is not reached. Try to increase wait time.
LSN reached
-----
 f
(1 row)
```

Wait until the specified LSN is replayed:

```
WAITLSN '0/3F07A611';
LSN reached
-----
```

```
t  
(1 row)
```

Limit LSN wait time to 500000 milliseconds, and then cancel the command:

```
WAITLSN '0/3F0FF791' TIMEOUT 500000;  
^Ccancel request sent  
NOTICE: LSN is not reached. Try to increase wait time.  
ERROR: canceling statement due to user request  
LSN reached  
-----  
f  
(1 row)
```

## Compatibility

There is no `WAITLSN` statement in the SQL standard.

---

# Postgres Pro Client Applications

This part contains reference information for Postgres Pro client applications and utilities. Not all of these commands are of general utility; some might require special privileges. The common feature of these applications is that they can be run on any host, independent of where the database server resides.

When specified on the command line, user and database names have their case preserved — the presence of spaces or special characters might require quoting. Table names and other identifiers do not have their case preserved, except where documented, and might require quoting.

---

# clusterdb

clusterdb — cluster a Postgres Pro database

## Synopsis

```
clusterdb [connection-option...] [ --verbose | -v ] [ --table | -t table ] ... [dbname]
```

```
clusterdb [connection-option...] [ --verbose | -v ] --all | -a
```

## Description

clusterdb is a utility for recluster tables in a Postgres Pro database. It finds tables that have previously been clustered, and clusters them again on the same index that was last used. Tables that have never been clustered are not affected.

clusterdb is a wrapper around the SQL command [CLUSTER](#). There is no effective difference between clustering databases via this utility and via other methods for accessing the server.

## Options

clusterdb accepts the following command-line arguments:

```
-a  
--all
```

Cluster all databases.

```
[-d] dbname  
[--dbname=] dbname
```

Specifies the name of the database to be clustered, when `-a/--all` is not used. If this is not specified, the database name is read from the environment variable `PGDATABASE`. If that is not set, the user name specified for the connection is used. The *dbname* can be a [connection string](#). If so, connection string parameters will override any conflicting command line options.

```
-e  
--echo
```

Echo the commands that clusterdb generates and sends to the server.

```
-q  
--quiet
```

Do not display progress messages.

```
-t table  
--table=table
```

Cluster *table* only. Multiple tables can be clustered by writing multiple `-t` switches.

```
-v  
--verbose
```

Print detailed information during processing.

```
-V  
--version
```

Print the clusterdb version and exit.

-?  
--help

Show help about clusterdb command line arguments, and exit.

clusterdb also accepts the following command-line arguments for connection parameters:

-h *host*  
--host=*host*

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

-p *port*  
--port=*port*

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

-U *username*  
--username=*username*

User name to connect as.

-w  
--no-password

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

-W  
--password

Force clusterdb to prompt for a password before connecting to a database.

This option is never essential, since clusterdb will automatically prompt for a password if the server demands password authentication. However, clusterdb will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-w` to avoid the extra connection attempt.

--maintenance-db=*dbname*

Specifies the name of the database to connect to to discover which databases should be clustered, when `-a/--all` is used. If not specified, the `postgres` database will be used, or if that does not exist, `template1` will be used. This can be a [connection string](#). If so, connection string parameters will override any conflicting command line options. Also, connection string parameters other than the database name itself will be re-used when connecting to other databases.

## Environment

PGDATABASE  
PGHOST  
PGPORT  
PGUSER

Default connection parameters

PG\_COLOR

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by libpq (see [Section 31.14](#)).

## Diagnostics

In case of difficulty, see [CLUSTER](#) and [psql](#) for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

## Examples

To cluster the database `test`:

```
$ clusterdb test
```

To cluster a single table `foo` in a database named `xyzyz`:

```
$ clusterdb --table=foo xyzyz
```

## See Also

[CLUSTER](#)

---

# createdb

createdb — create a new Postgres Pro database

## Synopsis

```
createdb [connection-option...] [option...] [dbname [description]]
```

## Description

createdb creates a new Postgres Pro database.

Normally, the database user who executes this command becomes the owner of the new database. However, a different owner can be specified via the `-o` option, if the executing user has appropriate privileges.

createdb is a wrapper around the SQL command [CREATE DATABASE](#). There is no effective difference between creating databases via this utility and via other methods for accessing the server.

## Options

createdb accepts the following command-line arguments:

*dbname*

Specifies the name of the database to be created. The name must be unique among all Postgres Pro databases in this cluster. The default is to create a database with the same name as the current system user.

*description*

Specifies a comment to be associated with the newly created database.

`-D tablespace`

`--tablespace=tablespace`

Specifies the default tablespace for the database. (This name is processed as a double-quoted identifier.)

`-e`

`--echo`

Echo the commands that createdb generates and sends to the server.

`-E encoding`

`--encoding=encoding`

Specifies the character encoding scheme to be used in this database. The character sets supported by the Postgres Pro server are described in [Section 22.3.1](#).

`-l locale[@provider]`

`--locale=locale[@provider]`

Specifies the locale to be used in this database. This is equivalent to specifying both `--lc-collate` and `--lc-ctype`.

Optionally, you can specify the provider of the default collation after the `@` symbol. Supported values are `icu` and `libc`. For details, see [Section 22.2.2](#).

`--lc-collate=locale[@provider]`

Specifies the LC\_COLLATE setting to be used in this database.

Optionally, you can specify the provider of the default collation after the @ symbol. Supported values are `icu` and `libc`. For details, see [Section 22.2.2](#).

`--lc-ctype=locale`

Specifies the `LC_CTYPE` setting to be used in this database.

`-O owner`

`--owner=owner`

Specifies the database user who will own the new database. (This name is processed as a double-quoted identifier.)

`-T template`

`--template=template`

Specifies the template database from which to build this database. (This name is processed as a double-quoted identifier.)

`-V`

`--version`

Print the `createdb` version and exit.

`-?`

`--help`

Show help about `createdb` command line arguments, and exit.

The options `-D`, `-l`, `-E`, `-O`, and `-T` correspond to options of the underlying SQL command [CREATE DATABASE](#); see there for more information about them.

`createdb` also accepts the following command-line arguments for connection parameters:

`-h host`

`--host=host`

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

`-p port`

`--port=port`

Specifies the TCP port or the local Unix domain socket file extension on which the server is listening for connections.

`-U username`

`--username=username`

User name to connect as.

`-w`

`--no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`

`--password`

Force `createdb` to prompt for a password before connecting to a database.

This option is never essential, since `createdb` will automatically prompt for a password if the server demands password authentication. However, `createdb` will waste a connection attempt finding out

that the server wants a password. In some cases it is worth typing `-w` to avoid the extra connection attempt.

```
--maintenance-db=dbname
```

Specifies the name of the database to connect to when creating the new database. If not specified, the `postgres` database will be used; if that does not exist (or if it is the name of the new database being created), `template1` will be used. This can be a [connection string](#). If so, connection string parameters will override any conflicting command line options.

## Environment

`PGDATABASE`

If set, the name of the database to create, unless overridden on the command line.

`PGHOST`

`PGPORT`

`PGUSER`

Default connection parameters. `PGUSER` also determines the name of the database to create, if it is not specified on the command line or by `PGDATABASE`.

`PG_COLOR`

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by `libpq` (see [Section 31.14](#)).

## Diagnostics

In case of difficulty, see [CREATE DATABASE](#) and [psql](#) for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the `libpq` front-end library will apply.

## Examples

To create the database `demo` using the default database server:

```
$ createdb demo
```

To create the database `demo` using the server on host `eden`, port 5000, using the `template0` template database, here is the command-line command and the underlying SQL command:

```
$ createdb -p 5000 -h eden -T template0 -e demo  
CREATE DATABASE demo TEMPLATE template0;
```

[dropdb](#), [CREATE DATABASE](#)

---

# createuser

createuser — define a new Postgres Pro user account

## Synopsis

```
createuser [connection-option...] [option...] [username]
```

## Description

createuser creates a new Postgres Pro user (or more precisely, a role). Only superusers and users with `CREATEROLE` privilege can create new users, so createuser must be invoked by someone who can connect as a superuser or a user with `CREATEROLE` privilege.

If you wish to create a new superuser, you must connect as a superuser, not merely with `CREATEROLE` privilege. Being a superuser implies the ability to bypass all access permission checks within the database, so superuser access should not be granted lightly.

createuser is a wrapper around the SQL command `CREATE ROLE`. There is no effective difference between creating users via this utility and via other methods for accessing the server.

## Options

createuser accepts the following command-line arguments:

*username*

Specifies the name of the Postgres Pro user to be created. This name must be different from all existing roles in this Postgres Pro installation.

`-c` *number*

`--connection-limit=number`

Set a maximum number of connections for the new user. The default is to set no limit.

`-d`

`--createdb`

The new user will be allowed to create databases.

`-D`

`--no-createdb`

The new user will not be allowed to create databases. This is the default.

`-e`

`--echo`

Echo the commands that createuser generates and sends to the server.

`-E`

`--encrypted`

This option is obsolete but still accepted for backward compatibility.

`-g` *role*

`--role=role`

Indicates role to which this role will be added immediately as a new member. Multiple roles to which this role will be added as a member can be specified by writing multiple `-g` switches.

`-i`  
`--inherit`  
The new role will automatically inherit privileges of roles it is a member of. This is the default.

`-I`  
`--no-inherit`  
The new role will not automatically inherit privileges of roles it is a member of.

`--interactive`  
Prompt for the user name if none is specified on the command line, and also prompt for whichever of the options `-d/-D`, `-r/-R`, `-s/-S` is not specified on the command line. (This was the default behavior up to PostgreSQL 9.1.)

`-l`  
`--login`  
The new user will be allowed to log in (that is, the user name can be used as the initial session user identifier). This is the default.

`-L`  
`--no-login`  
The new user will not be allowed to log in. (A role without login privilege is still useful as a means of managing database permissions.)

`-P`  
`--pwprompt`  
If given, createuser will issue a prompt for the password of the new user. This is not necessary if you do not plan on using password authentication.

`-r`  
`--createrole`  
The new user will be allowed to create new roles (that is, this user will have `CREATEROLE` privilege).

`-R`  
`--no-createrole`  
The new user will not be allowed to create new roles. This is the default.

`-s`  
`--superuser`  
The new user will be a superuser.

`-S`  
`--no-superuser`  
The new user will not be a superuser. This is the default.

`-V`  
`--version`  
Print the createuser version and exit.

`--replication`  
The new user will have the `REPLICATION` privilege, which is described more fully in the documentation for [CREATE ROLE](#).

`--no-replication`  
The new user will not have the `REPLICATION` privilege, which is described more fully in the documentation for [CREATE ROLE](#).

-?  
--help

Show help about createuser command line arguments, and exit.

createuser also accepts the following command-line arguments for connection parameters:

-h *host*  
--host=*host*

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

-p *port*  
--port=*port*

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

-U *username*  
--username=*username*

User name to connect as (not the user name to create).

-w  
--no-password

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

-W  
--password

Force createuser to prompt for a password (for connecting to the server, not for the password of the new user).

This option is never essential, since createuser will automatically prompt for a password if the server demands password authentication. However, createuser will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-w` to avoid the extra connection attempt.

## Environment

PGHOST  
PGPORT  
PGUSER

Default connection parameters

PG\_COLOR

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by libpq (see [Section 31.14](#)).

## Diagnostics

In case of difficulty, see [CREATE ROLE](#) and [psql](#) for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

## Examples

To create a user `joe` on the default database server:

```
$ createuser joe
```

To create a user `joe` on the default database server with prompting for some additional attributes:

```
$ createuser --interactive joe
```

```
Shall the new role be a superuser? (y/n) n
```

```
Shall the new role be allowed to create databases? (y/n) n
```

```
Shall the new role be allowed to create more new roles? (y/n) n
```

To create the same user `joe` using the server on host `eden`, port `5000`, with attributes explicitly specified, taking a look at the underlying command:

```
$ createuser -h eden -p 5000 -S -D -R -e joe
```

```
CREATE ROLE joe NOSUPERUSER NOCREATEDB NOCREATEROLE INHERIT LOGIN;
```

To create the user `joe` as a superuser, and assign a password immediately:

```
$ createuser -P -s -e joe
```

```
Enter password for new role: xyzyy
```

```
Enter it again: xyzyy
```

```
CREATE ROLE joe PASSWORD 'md5b5f5ba1a423792b526f799ae4eb3d59e' SUPERUSER CREATEDB  
CREATEROLE INHERIT LOGIN;
```

In the above example, the new password isn't actually echoed when typed, but we show what was typed for clarity. As you see, the password is encrypted before it is sent to the client.

# dropdb

dropdb — remove a Postgres Pro database

## Synopsis

```
dropdb [connection-option...] [option...] dbname
```

## Description

dropdb destroys an existing Postgres Pro database. The user who executes this command must be a database superuser or the owner of the database.

dropdb is a wrapper around the SQL command [DROP DATABASE](#). There is no effective difference between dropping databases via this utility and via other methods for accessing the server.

## Options

dropdb accepts the following command-line arguments:

*dbname*

Specifies the name of the database to be removed.

-e

--echo

Echo the commands that dropdb generates and sends to the server.

-f

--force

Attempt to terminate all existing connections to the target database before dropping it. See [DROP DATABASE](#) for more information on this option.

-i

--interactive

Issues a verification prompt before doing anything destructive.

-V

--version

Print the dropdb version and exit.

--if-exists

Do not throw an error if the database does not exist. A notice is issued in this case.

-?

--help

Show help about dropdb command line arguments, and exit.

dropdb also accepts the following command-line arguments for connection parameters:

-h *host*

--host=*host*

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

`-p port`  
`--port=port`

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

`-U username`  
`--username=username`

User name to connect as.

`-w`  
`--no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`  
`--password`

Force dropdb to prompt for a password before connecting to a database.

This option is never essential, since dropdb will automatically prompt for a password if the server demands password authentication. However, dropdb will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-w` to avoid the extra connection attempt.

`--maintenance-db=dbname`

Specifies the name of the database to connect to in order to drop the target database. If not specified, the `postgres` database will be used; if that does not exist (or is the database being dropped), `template1` will be used. This can be a [connection string](#). If so, connection string parameters will override any conflicting command line options.

## Environment

`PGHOST`  
`PGPORT`  
`PGUSER`

Default connection parameters

`PG_COLOR`

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by libpq (see [Section 31.14](#)).

## Diagnostics

In case of difficulty, see [DROP DATABASE](#) and [psql](#) for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

## Examples

To destroy the database `demo` on the default database server:

```
$ dropdb demo
```

To destroy the database `demo` using the server on host `eden`, port 5000, with verification and a peek at the underlying command:

```
$ dropdb -p 5000 -h eden -i -e demo
Database "demo" will be permanently deleted.
Are you sure? (y/n) y
DROP DATABASE demo;
```

## See Also

[createdb](#), [DROP DATABASE](#)

---

# dropuser

dropuser — remove a Postgres Pro user account

## Synopsis

```
dropuser [connection-option...] [option...] [username]
```

## Description

dropuser removes an existing Postgres Pro user. Only superusers and users with the `CREATEROLE` privilege can remove Postgres Pro users. (To remove a superuser, you must yourself be a superuser.)

dropuser is a wrapper around the SQL command `DROP ROLE`. There is no effective difference between dropping users via this utility and via other methods for accessing the server.

## Options

dropuser accepts the following command-line arguments:

*username*

Specifies the name of the Postgres Pro user to be removed. You will be prompted for a name if none is specified on the command line and the `-i/--interactive` option is used.

`-e`  
`--echo`

Echo the commands that dropuser generates and sends to the server.

`-i`  
`--interactive`

Prompt for confirmation before actually removing the user, and prompt for the user name if none is specified on the command line.

`-V`  
`--version`

Print the dropuser version and exit.

`--if-exists`

Do not throw an error if the user does not exist. A notice is issued in this case.

`-?`  
`--help`

Show help about dropuser command line arguments, and exit.

dropuser also accepts the following command-line arguments for connection parameters:

`-h host`  
`--host=host`

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

`-p port`  
`--port=port`

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

```
-U username
--username=username
```

User name to connect as (not the user name to drop).

```
-w
--no-password
```

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

```
-W
--password
```

Force dropuser to prompt for a password before connecting to a database.

This option is never essential, since dropuser will automatically prompt for a password if the server demands password authentication. However, dropuser will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-w` to avoid the extra connection attempt.

## Environment

```
PGHOST
PGPORT
PGUSER
```

Default connection parameters

```
PG_COLOR
```

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by libpq (see [Section 31.14](#)).

## Diagnostics

In case of difficulty, see [DROP ROLE](#) and [psql](#) for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

## Examples

To remove user `joe` from the default database server:

```
$ dropuser joe
```

To remove user `joe` using the server on host `eden`, port 5000, with verification and a peek at the underlying command:

```
$ dropuser -p 5000 -h eden -i -e joe
Role "joe" will be permanently removed.
Are you sure? (y/n) y
DROP ROLE joe;
```

## See Also

[createuser](#), [DROP ROLE](#)

---

# eCPg

eCPg — embedded SQL C preprocessor

## Synopsis

```
eCPg [option...] file...
```

## Description

eCPg is the embedded SQL preprocessor for C programs. It converts C programs with embedded SQL statements to normal C code by replacing the SQL invocations with special function calls. The output files can then be processed with any C compiler tool chain.

eCPg will convert each input file given on the command line to the corresponding C output file. If an input file name does not have any extension, .pgc is assumed. The file's extension will be replaced by .c to construct the output file name. But the output file name can be overridden using the -o option.

If an input file name is just -, eCPg reads the program from standard input (and writes to standard output, unless that is overridden with -o).

This reference page does not describe the embedded SQL language. See [Chapter 33](#) for more information on that topic.

## Options

eCPg accepts the following command-line arguments:

- c  
Automatically generate certain C code from SQL code. Currently, this works for EXEC SQL TYPE.
- C *mode*  
Set a compatibility mode. *mode* can be INFORMIX, INFORMIX\_SE, or ORACLE.
- D *symbol*  
Define a C preprocessor symbol.
- h  
Process header files. When this option is specified, the output file extension becomes .h not .c, and the default input file extension is .pgh not .pgc. Also, the -c option is forced on.
- i  
Parse system include files as well.
- I *directory*  
Specify an additional include path, used to find files included via EXEC SQL INCLUDE. Defaults are . (current directory), /usr/local/include, the Postgres Pro include directory which is defined at compile time (default: /usr/local/pgsql/include), and /usr/include, in that order.
- o *filename*  
Specifies that eCPg should write all its output to the given *filename*. Write -o - to send all output to standard output.
- r *option*  
Selects run-time behavior. *option* can be one of the following:

`no_indicator`

Do not use indicators but instead use special values to represent null values. Historically there have been databases using this approach.

`prepare`

Prepare all statements before using them. Libecpg will keep a cache of prepared statements and reuse a statement if it gets executed again. If the cache runs full, libecpg will free the least used statement.

`questionmarks`

Allow question mark as placeholder for compatibility reasons. This used to be the default long ago.

`-t`

Turn on autocommit of transactions. In this mode, each SQL command is automatically committed unless it is inside an explicit transaction block. In the default mode, commands are committed only when `EXEC SQL COMMIT` is issued.

`-v`

Print additional information including the version and the "include" path.

`--version`

Print the ecpg version and exit.

`-?`

`--help`

Show help about ecpg command line arguments, and exit.

## Notes

When compiling the preprocessed C code files, the compiler needs to be able to find the ECPG header files in the Postgres Pro include directory. Therefore, you might have to use the `-I` option when invoking the compiler (e.g., `-I/usr/local/pgsql/include`).

Programs using C code with embedded SQL have to be linked against the `libecpg` library, for example using the linker options `-L/usr/local/pgsql/lib -lecpg`.

The value of either of these directories that is appropriate for the installation can be found out using [pg\\_config](#).

## Examples

If you have an embedded SQL C source file named `prog1.pgc`, you can create an executable program using the following sequence of commands:

```
ecpg prog1.pgc
cc -I/usr/local/pgsql/include -c prog1.c
cc -o prog1 prog1.o -L/usr/local/pgsql/lib -lecpg
```

---

# pg\_basebackup

pg\_basebackup — take a base backup of a Postgres Pro cluster

## Synopsis

```
pg_basebackup [option...]
```

## Description

pg\_basebackup is used to take a base backup of a running Postgres Pro database cluster. The backup is taken without affecting other clients of the database, and can be used both for point-in-time recovery (see [Section 24.3](#)) and as the starting point for a log-shipping or streaming-replication standby server (see [Section 25.2](#)).

pg\_basebackup makes an exact copy of the database cluster's files, while making sure the server is put into and out of backup mode automatically. Backups are always taken of the entire database cluster; it is not possible to back up individual databases or database objects. For selective backups, another tool such as [pg\\_dump](#) must be used.

The backup is made over a regular Postgres Pro connection that uses the replication protocol. The connection must be made with a user ID that has `REPLICATION` permissions (see [Section 20.2](#)) or is a superuser, and `pg_hba.conf` must permit the replication connection. The server must also be configured with `max_wal_senders` set high enough to provide at least one walsender for the backup plus one for WAL streaming (if used).

There can be multiple `pg_basebackups` running at the same time, but it is usually better from a performance point of view to take only one backup, and copy the result.

pg\_basebackup can make a base backup from not only a primary server but also a standby. To take a backup from a standby, set up the standby so that it can accept replication connections (that is, set `max_wal_senders` and [hot standby](#), and configure its `pg_hba.conf` appropriately). You will also need to enable [full\\_page\\_writes](#) on the primary.

Note that there are some limitations in taking a backup from a standby:

- The backup history file is not created in the database cluster backed up.
- pg\_basebackup cannot force the standby to switch to a new WAL file at the end of backup. When you are using `-X none`, if write activity on the primary is low, pg\_basebackup may need to wait a long time for the last WAL file required for the backup to be switched and archived. In this case, it may be useful to run `pg_switch_wal` on the primary in order to trigger an immediate WAL file switch.
- If the standby is promoted to be primary during backup, the backup fails.
- All WAL records required for the backup must contain sufficient full-page writes, which requires you to enable `full_page_writes` on the primary and not to use a tool like `pg_compresslog` as `archive_command` to remove full-page writes from WAL files.

Whenever pg\_basebackup is taking a base backup, the server's `pg_stat_progress_basebackup` view will report the progress of the backup. See [Section 26.4.5](#) for details.

## Options

The following command-line options control the location and format of the output:

```
-D directory  
--pgdata=directory
```

Sets the target directory to write the output to. pg\_basebackup will create this directory (and any missing parent directories) if it does not exist. If it already exists, it must be empty.

When the backup is in tar format, the target directory may be specified as - (dash), causing the tar file to be written to `stdout`.

This option is required.

`-F format`

`--format=format`

Selects the format for the output. *format* can be one of the following:

p

plain

Write the output as plain files, with the same layout as the source server's data directory and tablespaces. When the cluster has no additional tablespaces, the whole database will be placed in the target directory. If the cluster contains additional tablespaces, the main data directory will be placed in the target directory, but all other tablespaces will be placed in the same absolute path as they have on the source server. (See `--tablespace-mapping` to change that.)

This is the default format.

t

tar

Write the output as tar files in the target directory. The main data directory's contents will be written to a file named `base.tar`, and each other tablespace will be written to a separate tar file named after that tablespace's OID.

If the target directory is specified as - (dash), the tar contents will be written to standard output, suitable for piping to (for example) `gzip`. This is only allowed if the cluster has no additional tablespaces and WAL streaming is not used.

`-R`

`--write-recovery-conf`

Creates a `standby.signal` file and appends connection settings to the `postgresql.auto.conf` file in the target directory (or within the base archive file when using tar format). This eases setting up a standby server using the results of the backup.

The `postgresql.auto.conf` file will record the connection settings and, if specified, the replication slot that `pg_basebackup` is using, so that streaming replication will use the same settings later on.

`-T olddir=newdir`

`--tablespace-mapping=olddir=newdir`

Relocates the tablespace in directory *olddir* to *newdir* during the backup. To be effective, *olddir* must exactly match the path specification of the tablespace as it is defined on the source server. (But it is not an error if there is no tablespace in *olddir* on the source server.) Meanwhile *newdir* is a directory in the receiving host's filesystem. As with the main target directory, *newdir* need not exist already, but if it does exist it must be empty. Both *olddir* and *newdir* must be absolute paths. If either path needs to contain an equal sign (=), precede that with a backslash. This option can be specified multiple times for multiple tablespaces.

If a tablespace is relocated in this way, the symbolic links inside the main data directory are updated to point to the new location. So the new data directory is ready to be used for a new server instance with all tablespaces in the updated locations.

Currently, this option only works with plain output format; it is ignored if tar format is selected.

`--waldir=waldir`

Sets the directory to write WAL (write-ahead log) files to. By default WAL files will be placed in the `pg_wal` subdirectory of the target directory, but this option can be used to place them elsewhere.

*waldir* must be an absolute path. As with the main target directory, *waldir* need not exist already, but if it does exist it must be empty. This option can only be specified when the backup is in plain format.

`-X method`

`--wal-method=method`

Includes the required WAL (write-ahead log) files in the backup. This will include all write-ahead logs generated during the backup. Unless the method `none` is specified, it is possible to start a postmaster in the target directory without the need to consult the log archive, thus making the output a completely standalone backup.

The following *methods* for collecting the write-ahead logs are supported:

`n`

`none`

Don't include write-ahead logs in the backup.

`f`

`fetch`

The write-ahead log files are collected at the end of the backup. Therefore, it is necessary for the source server's `wal_keep_size` parameter to be set high enough that the required log data is not removed before the end of the backup. If the required log data has been recycled before it's time to transfer it, the backup will fail and be unusable.

When tar format is used, the write-ahead log files will be included in the `base.tar` file.

`s`

`stream`

Stream write-ahead log data while the backup is being taken. This method will open a second connection to the server and start streaming the write-ahead log in parallel while running the backup. Therefore, it will require two replication connections not just one. As long as the client can keep up with the write-ahead log data, using this method requires no extra write-ahead logs to be saved on the source server.

When tar format is used, the write-ahead log files will be written to a separate file named `pg_wal.tar` (if the server is a version earlier than 10, the file will be named `pg_xlog.tar`).

This value is the default.

`-z`

`--gzip`

Enables gzip compression of tar file output, with the default compression level. Compression is only available when using the tar format, and the suffix `.gz` will automatically be added to all tar filenames.

`-Z level`

`--compress=level`

Enables gzip compression of tar file output, and specifies the compression level (0 through 9, 0 being no compression and 9 being best compression). Compression is only available when using the tar format, and the suffix `.gz` will automatically be added to all tar filenames.

The following command-line options control the generation of the backup and the invocation of the program:

`-c fast/spread`

`--checkpoint=fast/spread`

Sets checkpoint mode to fast (immediate) or spread (the default) (see [Section 24.3.3](#)).

-C  
--create-slot

Specifies that the replication slot named by the `--slot` option should be created before starting the backup. An error is raised if the slot already exists.

-l *label*  
--label=*label*

Sets the label for the backup. If none is specified, a default value of “`pg_basebackup base backup`” will be used.

-n  
--no-clean

By default, when `pg_basebackup` aborts with an error, it removes any directories it might have created before discovering that it cannot finish the job (for example, the target directory and write-ahead log directory). This option inhibits tidying-up and is thus useful for debugging.

Note that tablespace directories are not cleaned up either way.

-N  
--no-sync

By default, `pg_basebackup` will wait for all files to be written safely to disk. This option causes `pg_basebackup` to return without waiting, which is faster, but means that a subsequent operating system crash can leave the base backup corrupt. Generally, this option is useful for testing but should not be used when creating a production installation.

-P  
--progress

Enables progress reporting. Turning this on will deliver an approximate progress report during the backup. Since the database may change during the backup, this is only an approximation and may not end at exactly 100%. In particular, when WAL log is included in the backup, the total amount of data cannot be estimated in advance, and in this case the estimated target size will increase once it passes the total estimate without WAL.

-r *rate*  
--max-rate=*rate*

Sets the maximum transfer rate at which data is collected from the source server. This can be useful to limit the impact of `pg_basebackup` on the server. Values are in kilobytes per second. Use a suffix of `M` to indicate megabytes per second. A suffix of `k` is also accepted, and has no effect. Valid values are between 32 kilobytes per second and 1024 megabytes per second.

This option always affects transfer of the data directory. Transfer of WAL files is only affected if the collection method is `fetch`.

-S *slotname*  
--slot=*slotname*

This option can only be used together with `-X stream`. It causes WAL streaming to use the specified replication slot. If the base backup is intended to be used as a streaming-replication standby using a replication slot, the standby should then use the same replication slot name as [primary\\_slot\\_name](#). This ensures that the primary server does not remove any necessary WAL data in the time between the end of the base backup and the start of streaming replication on the new standby.

The specified replication slot has to exist unless the option `-C` is also used.

If this option is not specified and the server supports temporary replication slots (version 10 and later), then a temporary replication slot is automatically used for WAL streaming.

- `-v`  
`--verbose`
- Enables verbose mode. Will output some extra steps during startup and shutdown, as well as show the exact file name that is currently being processed if progress reporting is also enabled.
- `--manifest-checksums=algorithm`
- Specifies the checksum algorithm that should be applied to each file included in the backup manifest. Currently, the available algorithms are `NONE`, `CRC32C`, `SHA224`, `SHA256`, `SHA384`, and `SHA512`. The default is `CRC32C`.
- If `NONE` is selected, the backup manifest will not contain any checksums. Otherwise, it will contain a checksum of each file in the backup using the specified algorithm. In addition, the manifest will always contain a `SHA256` checksum of its own contents. The `SHA` algorithms are significantly more CPU-intensive than `CRC32C`, so selecting one of them may increase the time required to complete the backup.
- Using a `SHA` hash function provides a cryptographically secure digest of each file for users who wish to verify that the backup has not been tampered with, while the `CRC32C` algorithm provides a checksum that is much faster to calculate; it is good at catching errors due to accidental changes but is not resistant to malicious modifications. Note that, to be useful against an adversary who has access to the backup, the backup manifest would need to be stored securely elsewhere or otherwise verified not to have been modified since the backup was taken.
- [pg\\_verifybackup](#) can be used to check the integrity of a backup against the backup manifest.
- `--manifest-force-encode`
- Forces all filenames in the backup manifest to be hex-encoded. If this option is not specified, only non-UTF8 filenames are hex-encoded. This option is mostly intended to test that tools which read a backup manifest file properly handle this case.
- `--no-estimate-size`
- Prevents the server from estimating the total amount of backup data that will be streamed, resulting in the `backup_total` column in the `pg_stat_progress_basebackup` view always being `NULL`.
- Without this option, the backup will start by enumerating the size of the entire database, and then go back and send the actual contents. This may make the backup take slightly longer, and in particular it will take longer before the first data is sent. This option is useful to avoid such estimation time if it's too long.
- This option is not allowed when using `--progress`.
- `--no-manifest`
- Disables generation of a backup manifest. If this option is not specified, the server will generate and send a backup manifest which can be verified using [pg\\_verifybackup](#). The manifest is a list of every file present in the backup with the exception of any WAL files that may be included. It also stores the size, last modification time, and an optional checksum for each file.
- `--no-slot`
- Prevents the creation of a temporary replication slot for the backup.
- By default, if log streaming is selected but no slot name is given with the `-s` option, then a temporary replication slot is created (if supported by the source server).
- The main purpose of this option is to allow taking a base backup when the server has no free replication slots. Using a replication slot is almost always preferred, because it prevents needed WAL from being removed by the server during the backup.

`--no-verify-checksums`

Disables verification of checksums, if they are enabled on the server the base backup is taken from.

By default, checksums are verified and checksum failures will result in a non-zero exit status. However, the base backup will not be removed in such a case, as if the `--no-clean` option had been used. Checksum verification failures will also be reported in the `pg_stat_database` view.

The following command-line options control the connection to the source server:

`-d connstr`

`--dbname=connstr`

Specifies parameters used to connect to the server, as a [connection string](#); these will override any conflicting command line options.

The option is called `--dbname` for consistency with other client applications, but because `pg_basebackup` doesn't connect to any particular database in the cluster, any database name in the connection string will be ignored.

`-h host`

`--host=host`

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for a Unix domain socket. The default is taken from the `PGHOST` environment variable, if set, else a Unix domain socket connection is attempted.

`-p port`

`--port=port`

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections. Defaults to the `PGPORT` environment variable, if set, or a compiled-in default.

`-s interval`

`--status-interval=interval`

Specifies the number of seconds between status packets sent back to the source server. Smaller values allow more accurate monitoring of backup progress from the server. A value of zero disables periodic status updates completely, although an update will still be sent when requested by the server, to avoid timeout-based disconnects. The default value is 10 seconds.

`-U username`

`--username=username`

Specifies the user name to connect as.

`-w`

`--no-password`

Prevents issuing a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`

`--password`

Forces `pg_basebackup` to prompt for a password before connecting to the source server.

This option is never essential, since `pg_basebackup` will automatically prompt for a password if the server demands password authentication. However, `pg_basebackup` will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-w` to avoid the extra connection attempt.

Other options are also available:

-V  
--version

Prints the pg\_basebackup version and exits.

-?  
--help

Shows help about pg\_basebackup command line arguments, and exits.

## Environment

This utility, like most other Postgres Pro utilities, uses the environment variables supported by libpq (see [Section 31.14](#)).

The environment variable `PG_COLOR` specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

## Notes

At the beginning of the backup, a checkpoint needs to be performed on the source server. This can take some time (especially if the option `--checkpoint=fast` is not used), during which `pg_basebackup` will appear to be idle.

The backup will include all files in the data directory and tablespaces, including the configuration files and any additional files placed in the directory by third parties, except certain temporary files managed by Postgres Pro. But only regular files and directories are copied, except that symbolic links used for tablespaces are preserved. Symbolic links pointing to certain directories known to Postgres Pro are copied as empty directories. Other symbolic links and special device files are skipped. See [Section 50.4](#) for the precise details.

In plain format, tablespaces will be backed up to the same path they have on the source server, unless the option `--tablespace-mapping` is used. Without this option, running a plain format base backup on the same host as the server will not work if tablespaces are in use, because the backup would have to be written to the same directory locations as the original tablespaces.

When tar format is used, it is the user's responsibility to unpack each tar file before starting a Postgres Pro server that uses the data. If there are additional tablespaces, the tar files for them need to be unpacked in the correct locations. In this case the symbolic links for those tablespaces will be created by the server according to the contents of the `tablespace_map` file that is included in the `base.tar` file.

`pg_basebackup` works with servers of the same or an older major version, down to 9.1. However, WAL streaming mode (`-X stream`) only works with server version 9.3 and later, and tar format (`--format=tar`) only works with server version 9.5 and later.

`pg_basebackup` will preserve group permissions for data files if group permissions are enabled on the source cluster.

## Examples

To create a base backup of the server at `mydbserver` and store it in the local directory `/usr/local/pgsql/data`:

```
$ pg_basebackup -h mydbserver -D /usr/local/pgsql/data
```

To create a backup of the local server with one compressed tar file for each tablespace, and store it in the directory `backup`, showing a progress report while running:

```
$ pg_basebackup -D backup -Ft -z -P
```

To create a backup of a single-tablespace local database and compress this with `bzip2`:

```
$ pg_basebackup -D - -Ft -X fetch | bzip2 > backup.tar.bz2
```

(This command will fail if there are multiple tablespaces in the database.)

To create a backup of a local database where the tablespace in `/opt/ts` is relocated to `./backup/ts`:

```
$ pg_basebackup -D backup/data -T /opt/ts=$(pwd)/backup/ts
```

# pgbench

pgbench — run a benchmark test on Postgres Pro

## Synopsis

```
pgbench -i [option...] [dbname]
```

```
pgbench [option...] [dbname]
```

## Description

pgbench is a simple program for running benchmark tests on Postgres Pro. It runs the same sequence of SQL commands over and over, possibly in multiple concurrent database sessions, and then calculates the average transaction rate (transactions per second). By default, pgbench tests a scenario that is loosely based on TPC-B, involving five `SELECT`, `UPDATE`, and `INSERT` commands per transaction. However, it is easy to test other cases by writing your own transaction script files.

Typical output from pgbench looks like:

```
transaction type: <builtin: TPC-B (sort of)>
scaling factor: 10
query mode: simple
number of clients: 10
number of threads: 1
number of transactions per client: 1000
number of transactions actually processed: 10000/10000
tps = 85.184871 (including connections establishing)
tps = 85.296346 (excluding connections establishing)
```

The first six lines report some of the most important parameter settings. The next line reports the number of transactions completed and intended (the latter being just the product of number of clients and number of transactions per client); these will be equal unless the run failed before completion. (In `-T` mode, only the actual number of transactions is printed.) The last two lines report the number of transactions per second, figured with and without counting the time to start database sessions.

The default TPC-B-like transaction test requires specific tables to be set up beforehand. pgbench should be invoked with the `-i` (initialize) option to create and populate these tables. (When you are testing a custom script, you don't need this step, but will instead need to do whatever setup your test needs.) Initialization looks like:

```
pgbench -i [ other-options ] dbname
```

where *dbname* is the name of the already-created database to test in. (You may also need `-h`, `-p`, and/or `-U` options to specify how to connect to the database server.)

### Caution

pgbench `-i` creates four tables `pgbench_accounts`, `pgbench_branches`, `pgbench_history`, and `pgbench_tellers`, destroying any existing tables of these names. Be very careful to use another database if you have tables having these names!

At the default “scale factor” of 1, the tables initially contain this many rows:

table	# of rows
pgbench_branches	1
pgbench_tellers	10

```
pgbench_accounts      100000
pgbench_history        0
```

You can (and, for most purposes, probably should) increase the number of rows by using the `-s` (scale factor) option. The `-F` (fillfactor) option might also be used at this point.

Once you have done the necessary setup, you can run your benchmark with a command that doesn't include `-i`, that is

```
pgbench [ options ] dbname
```

In nearly all cases, you'll need some options to make a useful test. The most important options are `-c` (number of clients), `-t` (number of transactions), `-T` (time limit), and `-f` (specify a custom script file). See below for a full list.

## Options

The following is divided into three subsections. Different options are used during database initialization and while running benchmarks, but some options are useful in both cases.

### Initialization Options

pgbench accepts the following command-line initialization arguments:

*dbname*

Specifies the name of the database to test in. If this is not specified, the environment variable `PGDATABASE` is used. If that is not set, the user name specified for the connection is used.

`-i`  
`--initialize`

Required to invoke initialization mode.

`-I init_steps`  
`--init-steps=init_steps`

Perform just a selected set of the normal initialization steps. *init\_steps* specifies the initialization steps to be performed, using one character per step. Each step is invoked in the specified order. The default is `dtgvp`. The available steps are:

**d (Drop)**

Drop any existing pgbench tables.

**t (create Tables)**

Create the tables used by the standard pgbench scenario, namely `pgbench_accounts`, `pgbench_branches`, `pgbench_history`, and `pgbench_tellers`.

**g or G (Generate data, client-side or server-side)**

Generate data and load it into the standard tables, replacing any data already present.

With `g` (client-side data generation), data is generated in `pgbench` client and then sent to the server. This uses the client/server bandwidth extensively through a `COPY`. Using `g` causes logging to print one message every 100,000 rows while generating data for the `pgbench_accounts` table.

With `G` (server-side data generation), only small queries are sent from the `pgbench` client and then data is actually generated in the server. No significant bandwidth is required for this variant, but the server will do more work. Using `G` causes logging not to print any progress message while generating data.

The default initialization behavior uses client-side data generation (equivalent to `g`).

**v** (Vacuum)

Invoke `VACUUM` on the standard tables.

**p** (create Primary keys)

Create primary key indexes on the standard tables.

**f** (create Foreign keys)

Create foreign key constraints between the standard tables. (Note that this step is not performed by default.)

`-F fillfactor`

`--fillfactor=fillfactor`

Create the `pgbench_accounts`, `pgbench_tellers` and `pgbench_branches` tables with the given fillfactor. Default is 100.

`-n`

`--no-vacuum`

Perform no vacuuming during initialization. (This option suppresses the `v` initialization step, even if it was specified in `-I`.)

`-q`

`--quiet`

Switch logging to quiet mode, producing only one progress message per 5 seconds. The default logging prints one message each 100,000 rows, which often outputs many lines per second (especially on good hardware).

This setting has no effect if `G` is specified in `-I`.

`-s scale_factor`

`--scale=scale_factor`

Multiply the number of rows generated by the scale factor. For example, `-s 100` will create 10,000,000 rows in the `pgbench_accounts` table. Default is 1. When the scale is 20,000 or larger, the columns used to hold account identifiers (`aid` columns) will switch to using larger integers (`bigint`), in order to be big enough to hold the range of account identifiers.

`--foreign-keys`

Create foreign key constraints between the standard tables. (This option adds the `f` step to the initialization step sequence, if it is not already present.)

`--index-tablespace=index_tablespace`

Create indexes in the specified tablespace, rather than the default tablespace.

`--partition-method=NAME`

Create a partitioned `pgbench_accounts` table with `NAME` method. Expected values are `range` or `hash`. This option requires that `--partitions` is set to non-zero. If unspecified, default is `range`.

`--partitions=NUM`

Create a partitioned `pgbench_accounts` table with `NUM` partitions of nearly equal size for the scaled number of accounts. Default is 0, meaning no partitioning.

`--tablespace=tablespace`

Create tables in the specified tablespace, rather than the default tablespace.

`--unlogged-tables`

Create all tables as unlogged tables, rather than permanent tables.

## Benchmarking Options

pgbench accepts the following command-line benchmarking arguments:

`-b scriptname[@weight]`

`--builtin=scriptname[@weight]`

Add the specified built-in script to the list of scripts to be executed. Available built-in scripts are: `tpcb-like`, `simple-update` and `select-only`. Unambiguous prefixes of built-in names are accepted. With the special name `list`, show the list of built-in scripts and exit immediately.

Optionally, write an integer weight after `@` to adjust the probability of selecting this script versus other ones. The default weight is 1. See below for details.

`-c clients`

`--client=clients`

Number of clients simulated, that is, number of concurrent database sessions. Default is 1.

`-C`

`--connect`

Establish a new connection for each transaction, rather than doing it just once per client session. This is useful to measure the connection overhead.

`-d`

`--debug`

Print debugging output.

`-D varname=value`

`--define=varname=value`

Define a variable for use by a custom script (see below). Multiple `-D` options are allowed.

`-f filename[@weight]`

`--file=filename[@weight]`

Add a transaction script read from `filename` to the list of scripts to be executed.

Optionally, write an integer weight after `@` to adjust the probability of selecting this script versus other ones. The default weight is 1. (To use a script file name that includes an `@` character, append a weight so that there is no ambiguity, for example `filen@me@1`.) See below for details.

`-j threads`

`--jobs=threads`

Number of worker threads within pgbench. Using more than one thread can be helpful on multi-CPU machines. Clients are distributed as evenly as possible among available threads. Default is 1.

`-l`

`--log`

Write information about each transaction to a log file. See below for details.

`-L limit`

`--latency-limit=limit`

Transactions that last more than `limit` milliseconds are counted and reported separately, as *late*.

When throttling is used (`--rate=...`), transactions that lag behind schedule by more than *limit* ms, and thus have no hope of meeting the latency limit, are not sent to the server at all. They are counted and reported separately as *skipped*.

`-M querymode`  
`--protocol=querymode`

Protocol to use for submitting queries to the server:

- `simple`: use simple query protocol.
- `extended`: use extended query protocol.
- `prepared`: use extended query protocol with prepared statements.

In the `prepared` mode, `pgbench` reuses the parse analysis result starting from the second query iteration, so `pgbench` runs faster than in other modes.

The default is simple query protocol. (See [Chapter 50](#) for more information.)

`-n`  
`--no-vacuum`

Perform no vacuuming before running the test. This option is *necessary* if you are running a custom test scenario that does not include the standard tables `pgbench_accounts`, `pgbench_branches`, `pgbench_history`, and `pgbench_tellers`.

`-N`  
`--skip-some-updates`

Run built-in simple-update script. Shorthand for `-b simple-update`.

`-P sec`  
`--progress=sec`

Show progress report every *sec* seconds. The report includes the time since the beginning of the run, the TPS since the last report, and the transaction latency average and standard deviation since the last report. Under throttling (`-R`), the latency is computed with respect to the transaction scheduled start time, not the actual transaction beginning time, thus it also includes the average schedule lag time.

`-r`  
`--report-latencies`

Report the average per-statement latency (execution time from the perspective of the client) of each command after the benchmark finishes. See below for details.

`-R rate`  
`--rate=rate`

Execute transactions targeting the specified rate instead of running as fast as possible (the default). The rate is given in transactions per second. If the targeted rate is above the maximum possible rate, the rate limit won't impact the results.

The rate is targeted by starting transactions along a Poisson-distributed schedule time line. The expected start time schedule moves forward based on when the client first started, not when the previous transaction ended. That approach means that when transactions go past their original scheduled end time, it is possible for later ones to catch up again.

When throttling is active, the transaction latency reported at the end of the run is calculated from the scheduled start times, so it includes the time each transaction had to wait for the previous transaction to finish. The wait time is called the schedule lag time, and its average and maximum are also reported separately. The transaction latency with respect to the actual transaction start time, i.e., the time

spent executing the transaction in the database, can be computed by subtracting the schedule lag time from the reported latency.

If `--latency-limit` is used together with `--rate`, a transaction can lag behind so much that it is already over the latency limit when the previous transaction ends, because the latency is calculated from the scheduled start time. Such transactions are not sent to the server, but are skipped altogether and counted separately.

A high schedule lag time is an indication that the system cannot process transactions at the specified rate, with the chosen number of clients and threads. When the average transaction execution time is longer than the scheduled interval between each transaction, each successive transaction will fall further behind, and the schedule lag time will keep increasing the longer the test run is. When that happens, you will have to reduce the specified transaction rate.

`-s scale_factor`  
`--scale=scale_factor`

Report the specified scale factor in `pgbench`'s output. With the built-in tests, this is not necessary; the correct scale factor will be detected by counting the number of rows in the `pgbench_branches` table. However, when testing only custom benchmarks (`-f` option), the scale factor will be reported as 1 unless this option is used.

`-S`  
`--select-only`

Run built-in select-only script. Shorthand for `-b select-only`.

`-t transactions`  
`--transactions=transactions`

Number of transactions each client runs. Default is 10.

`-T seconds`  
`--time=seconds`

Run the test for this many seconds, rather than a fixed number of transactions per client. `-t` and `-T` are mutually exclusive.

`-v`  
`--vacuum-all`

Vacuum all four standard tables before running the test. With neither `-n` nor `-v`, `pgbench` will vacuum the `pgbench_tellers` and `pgbench_branches` tables, and will truncate `pgbench_history`.

`--aggregate-interval=seconds`

Length of aggregation interval (in seconds). May be used only with `-l` option. With this option, the log contains per-interval summary data, as described below.

`--log-prefix=prefix`

Set the filename prefix for the log files created by `--log`. The default is `pgbench_log`.

`--progress-timestamp`

When showing progress (option `-P`), use a timestamp (Unix epoch) instead of the number of seconds since the beginning of the run. The unit is in seconds, with millisecond precision after the dot. This helps compare logs generated by various tools.

`--random-seed=seed`

Set random generator seed. Seeds the system random number generator, which then produces a sequence of initial generator states, one for each thread. Values for `seed` may be: `time` (the

default, the seed is based on the current time), `rand` (use a strong random source, failing if none is available), or an unsigned decimal integer value. The random generator is invoked explicitly from a `pgbench` script (`random...` functions) or implicitly (for instance option `--rate` uses it to schedule transactions). When explicitly set, the value used for seeding is shown on the terminal. Any value allowed for `seed` may also be provided through the environment variable `PGBENCH_RANDOM_SEED`. To ensure that the provided seed impacts all possible uses, put this option first or use the environment variable.

Setting the seed explicitly allows to reproduce a `pgbench` run exactly, as far as random numbers are concerned. As the random state is managed per thread, this means the exact same `pgbench` run for an identical invocation if there is one client per thread and there are no external or data dependencies. From a statistical viewpoint reproducing runs exactly is a bad idea because it can hide the performance variability or improve performance unduly, e.g., by hitting the same pages as a previous run. However, it may also be of great help for debugging, for instance re-running a tricky case which leads to an error. Use wisely.

`--sampling-rate=rate`

Sampling rate, used when writing data into the log, to reduce the amount of log generated. If this option is given, only the specified fraction of transactions are logged. 1.0 means all transactions will be logged, 0.05 means only 5% of the transactions will be logged.

Remember to take the sampling rate into account when processing the log file. For example, when computing TPS values, you need to multiply the numbers accordingly (e.g., with 0.01 sample rate, you'll only get 1/100 of the actual TPS).

`--show-script=scriptname`

Show the actual code of builtin script `scriptname` on stderr, and exit immediately.

## Common Options

`pgbench` also accepts the following common command-line arguments for connection parameters:

`-h hostname`

`--host=hostname`

The database server's host name

`-p port`

`--port=port`

The database server's port number

`-U login`

`--username=login`

The user name to connect as

`-V`

`--version`

Print the `pgbench` version and exit.

`-?`

`--help`

Show help about `pgbench` command line arguments, and exit.

## Exit Status

A successful run will exit with status 0. Exit status 1 indicates static problems such as invalid command-line options. Errors during the run such as database errors or problems in the script will result in exit status 2. In the latter case, `pgbench` will print partial results.

## Environment

```
PGDATABASE
PGHOST
PGPORT
PGUSER
```

Default connection parameters.

This utility, like most other Postgres Pro utilities, uses the environment variables supported by libpq (see [Section 31.14](#)).

The environment variable `PG_COLOR` specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

## Notes

### What Is the “Transaction” Actually Performed in pgbench?

pgbench executes test scripts chosen randomly from a specified list. The scripts may include built-in scripts specified with `-b` and user-provided scripts specified with `-f`. Each script may be given a relative weight specified after an `@` so as to change its selection probability. The default weight is 1. Scripts with a weight of 0 are ignored.

The default built-in transaction script (also invoked with `-b tpcb-like`) issues seven commands per transaction over randomly chosen `aid`, `tid`, `bid` and `delta`. The scenario is inspired by the TPC-B benchmark, but is not actually TPC-B, hence the name.

1. `BEGIN;`
2. `UPDATE pgbench_accounts SET abalance = abalance + :delta WHERE aid = :aid;`
3. `SELECT abalance FROM pgbench_accounts WHERE aid = :aid;`
4. `UPDATE pgbench_tellers SET tbalance = tbalance + :delta WHERE tid = :tid;`
5. `UPDATE pgbench_branches SET bbalance = bbalance + :delta WHERE bid = :bid;`
6. `INSERT INTO pgbench_history (tid, bid, aid, delta, mtime) VALUES (:tid, :bid, :aid, :delta, CURRENT_TIMESTAMP);`
7. `END;`

If you select the `simple-update` built-in (also `-N`), steps 4 and 5 aren't included in the transaction. This will avoid update contention on these tables, but it makes the test case even less like TPC-B.

If you select the `select-only` built-in (also `-S`), only the `SELECT` is issued.

## Custom Scripts

pgbench has support for running custom benchmark scenarios by replacing the default transaction script (described above) with a transaction script read from a file (`-f` option). In this case a “transaction” counts as one execution of a script file.

A script file contains one or more SQL commands terminated by semicolons. Empty lines and lines beginning with `--` are ignored. Script files can also contain “meta commands”, which are interpreted by pgbench itself, as described below.

### Note

Before Postgres Pro 9.6, SQL commands in script files were terminated by newlines, and so they could not be continued across lines. Now a semicolon is *required* to separate consecutive SQL

commands (though a SQL command does not need one if it is followed by a meta command). If you need to create a script file that works with both old and new versions of pgbench, be sure to write each SQL command on a single line ending with a semicolon.

There is a simple variable-substitution facility for script files. Variable names must consist of letters (including non-Latin letters), digits, and underscores, with the first character not being a digit. Variables can be set by the command-line `-D` option, explained above, or by the meta commands explained below. In addition to any variables preset by `-D` command-line options, there are a few variables that are preset automatically, listed in [Table 274](#). A value specified for these variables using `-D` takes precedence over the automatic presets. Once set, a variable's value can be inserted into a SQL command by writing `:variablename`. When running more than one client session, each session has its own set of variables. pgbench supports up to 255 variable uses in one statement.

**Table 274. pgbench Automatic Variables**

Variable	Description
<code>client_id</code>	unique number identifying the client session (starts from zero)
<code>default_seed</code>	seed used in hash functions by default
<code>random_seed</code>	random generator seed (unless overwritten with <code>-D</code> )
<code>scale</code>	current scale factor

Script file meta commands begin with a backslash (`\`) and normally extend to the end of the line, although they can be continued to additional lines by writing backslash-return. Arguments to a meta command are separated by white space. These meta commands are supported:

```
\gset [prefix] \aset [prefix]
```

These commands may be used to end SQL queries, taking the place of the terminating semicolon (`;`).

When the `\gset` command is used, the preceding SQL query is expected to return one row, the columns of which are stored into variables named after column names, and prefixed with `prefix` if provided.

When the `\aset` command is used, all combined SQL queries (separated by `\;`) have their columns stored into variables named after column names, and prefixed with `prefix` if provided. If a query returns no row, no assignment is made and the variable can be tested for existence to detect this. If a query returns more than one row, the last value is kept.

The following example puts the final account balance from the first query into variable `abalance`, and fills variables `p_two` and `p_three` with integers from the third query. The result of the second query is discarded. The result of the two last combined queries are stored in variables `four` and `five`.

```
UPDATE pgbench_accounts
  SET abalance = abalance + :delta
  WHERE aid = :aid
  RETURNING abalance \gset
-- compound of two queries
SELECT 1 \;
SELECT 2 AS two, 3 AS three \gset p_
SELECT 4 AS four \; SELECT 5 AS five \aset
```

```
\if expression
\elif expression
\else
\endif
```

This group of commands implements nestable conditional blocks, similarly to `psql`'s `\if expression`. Conditional expressions are identical to those with `\set`, with non-zero values interpreted as true.

```
\set varname expression
```

Sets variable *varname* to a value calculated from *expression*. The expression may contain the NULL constant, Boolean constants TRUE and FALSE, integer constants such as 5432, double constants such as 3.14159, references to variables *:variablename*, operators with their usual SQL precedence and associativity, function calls, SQL CASE generic conditional expressions and parentheses.

Functions and most operators return NULL on NULL input.

For conditional purposes, non zero numerical values are TRUE, zero numerical values and NULL are FALSE.

Too large or small integer and double constants, as well as integer arithmetic operators (+, -, \* and /) raise errors on overflows.

When no final ELSE clause is provided to a CASE, the default value is NULL.

Examples:

```
\set ntellers 10 * :scale
\set aid (1021 * random(1, 100000 * :scale)) % \
        (100000 * :scale) + 1
\set divx CASE WHEN :x <> 0 THEN :y/:x ELSE NULL END
```

```
\sleep number [ us | ms | s ]
```

Causes script execution to sleep for the specified duration in microseconds (*us*), milliseconds (*ms*) or seconds (*s*). If the unit is omitted then seconds are the default. *number* can be either an integer constant or a *:variablename* reference to a variable having an integer value.

Example:

```
\sleep 10 ms
```

```
\setshell varname command [ argument ... ]
```

Sets variable *varname* to the result of the shell command *command* with the given *argument(s)*. The command must return an integer value through its standard output.

*command* and each *argument* can be either a text constant or a *:variablename* reference to a variable. If you want to use an *argument* starting with a colon, write an additional colon at the beginning of *argument*.

Example:

```
\setshell variable_to_be_assigned command
        literal_argument :variable ::literal_starting_with_colon
```

```
\shell command [ argument ... ]
```

Same as `\setshell`, but the result of the command is discarded.

Example:

```
\shell command literal_argument :variable ::literal_starting_with_colon
```

## Built-in Operators

The arithmetic, bitwise, comparison and logical operators listed in [Table 275](#) are built into pgbench and may be used in expressions appearing in `\set`. The operators are listed in increasing precedence order. Except as noted, operators taking two numeric inputs will produce a double value if either input is double, otherwise they produce an integer result.

**Table 275. pgbench Operators**

<b>Operator</b>	<b>Description</b>	<b>Example(s)</b>
	<i>boolean</i> OR <i>boolean</i> → <i>boolean</i>	Logical OR 5 or 0 → TRUE
	<i>boolean</i> AND <i>boolean</i> → <i>boolean</i>	Logical AND 3 and 0 → FALSE
	NOT <i>boolean</i> → <i>boolean</i>	Logical NOT not false → TRUE
	<i>boolean</i> IS [NOT] (NULL TRUE FALSE) → <i>boolean</i>	Boolean value tests 1 is null → FALSE
	<i>value</i> ISNULL NOTNULL → <i>boolean</i>	Nullness tests 1 notnull → TRUE
	<i>number</i> = <i>number</i> → <i>boolean</i>	Equal 5 = 4 → FALSE
	<i>number</i> <> <i>number</i> → <i>boolean</i>	Not equal 5 <> 4 → TRUE
	<i>number</i> != <i>number</i> → <i>boolean</i>	Not equal 5 != 5 → FALSE
	<i>number</i> < <i>number</i> → <i>boolean</i>	Less than 5 < 4 → FALSE
	<i>number</i> <= <i>number</i> → <i>boolean</i>	Less than or equal to 5 <= 4 → FALSE
	<i>number</i> > <i>number</i> → <i>boolean</i>	Greater than 5 > 4 → TRUE
	<i>number</i> >= <i>number</i> → <i>boolean</i>	Greater than or equal to 5 >= 4 → TRUE
	<i>integer</i>   <i>integer</i> → <i>integer</i>	Bitwise OR 1   2 → 3
	<i>integer</i> # <i>integer</i> → <i>integer</i>	Bitwise XOR

<b>Operator</b>	<b>Description</b>	<b>Example(s)</b>
		$1 \# 3 \rightarrow 2$
	<i>integer</i> & <i>integer</i> → <i>integer</i> Bitwise AND	$1 \& 3 \rightarrow 1$
	$\sim$ <i>integer</i> → <i>integer</i> Bitwise NOT	$\sim 1 \rightarrow -2$
	<i>integer</i> << <i>integer</i> → <i>integer</i> Bitwise shift left	$1 \ll 2 \rightarrow 4$
	<i>integer</i> >> <i>integer</i> → <i>integer</i> Bitwise shift right	$8 \gg 2 \rightarrow 2$
	<i>number</i> + <i>number</i> → <i>number</i> Addition	$5 + 4 \rightarrow 9$
	<i>number</i> - <i>number</i> → <i>number</i> Subtraction	$3 - 2.0 \rightarrow 1.0$
	<i>number</i> * <i>number</i> → <i>number</i> Multiplication	$5 * 4 \rightarrow 20$
	<i>number</i> / <i>number</i> → <i>number</i> Division (truncates the result towards zero if both inputs are integers)	$5 / 3 \rightarrow 1$
	<i>integer</i> % <i>integer</i> → <i>integer</i> Modulo (remainder)	$3 \% 2 \rightarrow 1$
	- <i>number</i> → <i>number</i> Negation	$- 2.0 \rightarrow -2.0$

## Built-In Functions

The functions listed in [Table 276](#) are built into pgbench and may be used in expressions appearing in `\set`.

**Table 276. pgbench Functions**

<b>Function</b>	<b>Description</b>	<b>Example(s)</b>
<code>abs ( <i>number</i> )</code>	→ same type as input Absolute value	<code>abs (-17) → 17</code>

<b>Function</b>	<b>Description</b>	<b>Example(s)</b>
<code>debug ( number )</code>	→ same type as input Prints the argument to stderr, and returns the argument.	<code>debug (5432.1) → 5432.1</code>
<code>double ( number )</code>	→ double Casts to double.	<code>double (5432) → 5432.0</code>
<code>exp ( number )</code>	→ double Exponential (e raised to the given power)	<code>exp (1.0) → 2.718281828459045</code>
<code>greatest ( number [, ... ] )</code>	→ double if any argument is double, else integer Selects the largest value among the arguments.	<code>greatest (5, 4, 3, 2) → 5</code>
<code>hash ( value [, seed ] )</code>	→ integer This is an alias for <code>hash_murmur2</code> .	<code>hash (10, 5432) → -5817877081768721676</code>
<code>hash_fnv1a ( value [, seed ] )</code>	→ integer Computes <i>FNv-1a hash</i> .	<code>hash_fnv1a (10, 5432) → -7793829335365542153</code>
<code>hash_murmur2 ( value [, seed ] )</code>	→ integer Computes <i>MurmurHash2 hash</i> .	<code>hash_murmur2 (10, 5432) → -5817877081768721676</code>
<code>int ( number )</code>	→ integer Casts to integer.	<code>int (5.4 + 3.8) → 9</code>
<code>least ( number [, ... ] )</code>	→ double if any argument is double, else integer Selects the smallest value among the arguments.	<code>least (5, 4, 3, 2.1) → 2.1</code>
<code>ln ( number )</code>	→ double Natural logarithm	<code>ln (2.718281828459045) → 1.0</code>
<code>mod ( integer, integer )</code>	→ integer Modulo (remainder)	<code>mod (54, 32) → 22</code>
<code>pi ()</code>	→ double Approximate value of $\pi$	<code>pi () → 3.14159265358979323846</code>
<code>pow ( x, y )</code> <code>power ( x, y )</code>	→ double → double $x$ raised to the power of $y$	<code>pow (2.0, 10) → 1024.0</code>
<code>random ( lb, ub )</code>	→ integer Computes a uniformly-distributed random integer in <code>[lb, ub]</code> .	

<b>Function</b>	<b>Description</b>	<b>Example(s)</b>
<code>random(1, 10)</code>	→ an integer between 1 and 10	
<code>random_exponential ( lb, ub, parameter )</code>	→ integer Computes an exponentially-distributed random integer in [lb, ub] , see below.	<code>random_exponential(1, 10, 3.0)</code> → an integer between 1 and 10
<code>random_gaussian ( lb, ub, parameter )</code>	→ integer Computes a Gaussian-distributed random integer in [lb, ub] , see below.	<code>random_gaussian(1, 10, 2.5)</code> → an integer between 1 and 10
<code>random_zipfian ( lb, ub, parameter )</code>	→ integer Computes a Zipfian-distributed random integer in [lb, ub] , see below.	<code>random_zipfian(1, 10, 1.5)</code> → an integer between 1 and 10
<code>sqrt ( number )</code>	→ double Square root	<code>sqrt(2.0)</code> → 1.414213562

The `random` function generates values using a uniform distribution, that is all the values are drawn within the specified range with equal probability. The `random_exponential`, `random_gaussian` and `random_zipfian` functions require an additional double parameter which determines the precise shape of the distribution.

- For an exponential distribution, `parameter` controls the distribution by truncating a quickly-decreasing exponential distribution at `parameter`, and then projecting onto integers between the bounds. To be precise, with

$$f(x) = \exp(-\text{parameter} * (x - \text{min}) / (\text{max} - \text{min} + 1)) / (1 - \exp(-\text{parameter}))$$

Then value `i` between `min` and `max` inclusive is drawn with probability:  $f(i) - f(i + 1)$ .

Intuitively, the larger the `parameter`, the more frequently values close to `min` are accessed, and the less frequently values close to `max` are accessed. The closer to 0 `parameter` is, the flatter (more uniform) the access distribution. A crude approximation of the distribution is that the most frequent 1% values in the range, close to `min`, are drawn `parameter%` of the time. The `parameter` value must be strictly positive.

- For a Gaussian distribution, the interval is mapped onto a standard normal distribution (the classical bell-shaped Gaussian curve) truncated at `-parameter` on the left and `+parameter` on the right. Values in the middle of the interval are more likely to be drawn. To be precise, if  $\text{PHI}(x)$  is the cumulative distribution function of the standard normal distribution, with mean `mu` defined as  $(\text{max} + \text{min}) / 2.0$ , with

$$f(x) = \text{PHI}(2.0 * \text{parameter} * (x - \text{mu}) / (\text{max} - \text{min} + 1)) / (2.0 * \text{PHI}(\text{parameter}) - 1)$$

then value `i` between `min` and `max` inclusive is drawn with probability:  $f(i + 0.5) - f(i - 0.5)$ . Intuitively, the larger the `parameter`, the more frequently values close to the middle of the interval are drawn, and the less frequently values close to the `min` and `max` bounds. About 67% of values are drawn from the middle  $1.0 / \text{parameter}$ , that is a relative  $0.5 / \text{parameter}$  around the mean, and 95% in the middle  $2.0 / \text{parameter}$ , that is a relative  $1.0 / \text{parameter}$  around the mean; for instance, if `parameter` is 4.0, 67% of values are drawn from the middle quarter ( $1.0 / 4.0$ ) of the interval (i.e., from  $3.0 / 8.0$  to  $5.0 / 8.0$ ) and 95% from the middle half ( $2.0 / 4.0$ ) of the interval (second and third quartiles). The minimum allowed `parameter` value is 2.0.

- `random_zipfian` generates a bounded Zipfian distribution. `parameter` defines how skewed the distribution is. The larger the `parameter`, the more frequently values closer to the beginning of the interval are drawn. The distribution is such that, assuming the range starts from 1, the

ratio of the probability of drawing  $k$  versus drawing  $k+1$  is  $((k+1)/k)**parameter$ . For example, `random_zipfian(1, ..., 2.5)` produces the value 1 about  $(2/1)**2.5 = 5.66$  times more frequently than 2, which itself is produced  $(3/2)**2.5 = 2.76$  times more frequently than 3, and so on.

pgbench's implementation is based on "Non-Uniform Random Variate Generation", Luc Devroye, p. 550-551, Springer 1986. Due to limitations of that algorithm, the *parameter* value is restricted to the range [1.001, 1000].

Hash functions `hash`, `hash_murmur2` and `hash_fnv1a` accept an input value and an optional seed parameter. In case the seed isn't provided the value of `:default_seed` is used, which is initialized randomly unless set by the command-line `-D` option. Hash functions can be used to scatter the distribution of random functions such as `random_zipfian` or `random_exponential`. For instance, the following pgbench script simulates possible real world workload typical for social media and blogging platforms where few accounts generate excessive load:

```
\set r random_zipfian(0, 100000000, 1.07)
\set k abs(hash(:r)) % 1000000
```

In some cases several distinct distributions are needed which don't correlate with each other and this is when implicit seed parameter comes in handy:

```
\set k1 abs(hash(:r, :default_seed + 123)) % 1000000
\set k2 abs(hash(:r, :default_seed + 321)) % 1000000
```

As an example, the full definition of the built-in TPC-B-like transaction is:

```
\set aid random(1, 100000 * :scale)
\set bid random(1, 1 * :scale)
\set tid random(1, 10 * :scale)
\set delta random(-5000, 5000)
BEGIN;
UPDATE pgbench_accounts SET abalance = abalance + :delta WHERE aid = :aid;
SELECT abalance FROM pgbench_accounts WHERE aid = :aid;
UPDATE pgbench_tellers SET tbalance = tbalance + :delta WHERE tid = :tid;
UPDATE pgbench_branches SET bbalance = bbalance + :delta WHERE bid = :bid;
INSERT INTO pgbench_history (tid, bid, aid, delta, mtime) VALUES
(:tid, :bid, :aid, :delta, CURRENT_TIMESTAMP);
END;
```

This script allows each iteration of the transaction to reference different, randomly-chosen rows. (This example also shows why it's important for each client session to have its own variables — otherwise they'd not be independently touching different rows.)

## Per-Transaction Logging

With the `-l` option (but without the `--aggregate-interval` option), pgbench writes information about each transaction to a log file. The log file will be named `prefix.nnn`, where `prefix` defaults to `pgbench_log`, and `nnn` is the PID of the pgbench process. The prefix can be changed by using the `--log-prefix` option. If the `-j` option is 2 or higher, so that there are multiple worker threads, each will have its own log file. The first worker will use the same name for its log file as in the standard single worker case. The additional log files for the other workers will be named `prefix.nnn.mmm`, where `mmm` is a sequential number for each worker starting with 1.

The format of the log is:

```
client_id transaction_no time script_no time_epoch time_us [ schedule_lag ]
```

where `client_id` indicates which client session ran the transaction, `transaction_no` counts how many transactions have been run by that session, `time` is the total elapsed transaction time in microseconds, `script_no` identifies which script file was used (useful when multiple scripts were specified with `-f` or `-b`), and `time_epoch/time_us` are a Unix-epoch time stamp and an offset in microseconds (suitable for creating an ISO 8601 time stamp with fractional seconds) showing when the transaction completed.

The *schedule\_lag* field is the difference between the transaction's scheduled start time, and the time it actually started, in microseconds. It is only present when the `--rate` option is used. When both `--rate` and `--latency-limit` are used, the *time* for a skipped transaction will be reported as `skipped`.

Here is a snippet of a log file generated in a single-client run:

```
0 199 2241 0 1175850568 995598
0 200 2465 0 1175850568 998079
0 201 2513 0 1175850569 608
0 202 2038 0 1175850569 2663
```

Another example with `--rate=100` and `--latency-limit=5` (note the additional *schedule\_lag* column):

```
0 81 4621 0 1412881037 912698 3005
0 82 6173 0 1412881037 914578 4304
0 83 skipped 0 1412881037 914578 5217
0 83 skipped 0 1412881037 914578 5099
0 83 4722 0 1412881037 916203 3108
0 84 4142 0 1412881037 918023 2333
0 85 2465 0 1412881037 919759 740
```

In this example, transaction 82 was late, because its latency (6.173 ms) was over the 5 ms limit. The next two transactions were skipped, because they were already late before they were even started.

When running a long test on hardware that can handle a lot of transactions, the log files can become very large. The `--sampling-rate` option can be used to log only a random sample of transactions.

## Aggregated Logging

With the `--aggregate-interval` option, a different format is used for the log files:

```
interval_start num_transactions sum_latency sum_latency_2 min_latency max_latency
[ sum_lag sum_lag_2 min_lag max_lag [ skipped ] ]
```

where *interval\_start* is the start of the interval (as a Unix epoch time stamp), *num\_transactions* is the number of transactions within the interval, *sum\_latency* is the sum of the transaction latencies within the interval, *sum\_latency\_2* is the sum of squares of the transaction latencies within the interval, *min\_latency* is the minimum latency within the interval, and *max\_latency* is the maximum latency within the interval. The next fields, *sum\_lag*, *sum\_lag\_2*, *min\_lag*, and *max\_lag*, are only present if the `--rate` option is used. They provide statistics about the time each transaction had to wait for the previous one to finish, i.e., the difference between each transaction's scheduled start time and the time it actually started. The very last field, *skipped*, is only present if the `--latency-limit` option is used, too. It counts the number of transactions skipped because they would have started too late. Each transaction is counted in the interval when it was committed.

Here is some example output:

```
1345828501 5601 1542744 483552416 61 2573
1345828503 7884 1979812 565806736 60 1479
1345828505 7208 1979422 567277552 59 1391
1345828507 7685 1980268 569784714 60 1398
1345828509 7073 1979779 573489941 236 1411
```

Notice that while the plain (unaggregated) log file shows which script was used for each transaction, the aggregated log does not. Therefore if you need per-script data, you need to aggregate the data on your own.

## Per-Statement Latencies

With the `-r` option, `pgbench` collects the elapsed transaction time of each statement executed by every client. It then reports an average of those values, referred to as the latency for each statement, after the benchmark has finished.

For the default script, the output will look similar to this:

```
starting vacuum...end.
transaction type: <builtin: TPC-B (sort of)>
scaling factor: 1
query mode: simple
number of clients: 10
number of threads: 1
number of transactions per client: 1000
number of transactions actually processed: 10000/10000
latency average = 15.844 ms
latency stddev = 2.715 ms
tps = 618.764555 (including connections establishing)
tps = 622.977698 (excluding connections establishing)
statement latencies in milliseconds:
    0.002  \set aid random(1, 100000 * :scale)
    0.005  \set bid random(1, 1 * :scale)
    0.002  \set tid random(1, 10 * :scale)
    0.001  \set delta random(-5000, 5000)
    0.326  BEGIN;
    0.603  UPDATE pgbench_accounts SET abalance = abalance + :delta WHERE aid
= :aid;
    0.454  SELECT abalance FROM pgbench_accounts WHERE aid = :aid;
    5.528  UPDATE pgbench_tellers SET tbalance = tbalance + :delta WHERE tid
= :tid;
    7.335  UPDATE pgbench_branches SET bbalance = bbalance + :delta WHERE bid
= :bid;
    0.371  INSERT INTO pgbench_history (tid, bid, aid, delta, mtime) VALUES
(:tid, :bid, :aid, :delta, CURRENT_TIMESTAMP);
    1.212  END;
```

If multiple script files are specified, the averages are reported separately for each script file.

Note that collecting the additional timing information needed for per-statement latency computation adds some overhead. This will slow average execution speed and lower the computed TPS. The amount of slowdown varies significantly depending on platform and hardware. Comparing average TPS values with and without latency reporting enabled is a good way to measure if the timing overhead is significant.

## Good Practices

It is very easy to use pgbench to produce completely meaningless numbers. Here are some guidelines to help you get useful results.

In the first place, *never* believe any test that runs for only a few seconds. Use the `-t` or `-T` option to make the run last at least a few minutes, so as to average out noise. In some cases you could need hours to get numbers that are reproducible. It's a good idea to try the test run a few times, to find out if your numbers are reproducible or not.

For the default TPC-B-like test scenario, the initialization scale factor (`-s`) should be at least as large as the largest number of clients you intend to test (`-c`); else you'll mostly be measuring update contention. There are only `-s` rows in the `pgbench_branches` table, and every transaction wants to update one of them, so `-c` values in excess of `-s` will undoubtedly result in lots of transactions blocked waiting for other transactions.

The default test scenario is also quite sensitive to how long it's been since the tables were initialized: accumulation of dead rows and dead space in the tables changes the results. To understand the results you must keep track of the total number of updates and when vacuuming happens. If autovacuum is enabled it can result in unpredictable changes in measured performance.

A limitation of pgbench is that it can itself become the bottleneck when trying to test a large number of client sessions. This can be alleviated by running pgbench on a different machine from the database

server, although low network latency will be essential. It might even be useful to run several pgbench instances concurrently, on several client machines, against the same database server.

## Security

If untrusted users have access to a database that has not adopted a [secure schema usage pattern](#), do not run pgbench in that database. pgbench uses unqualified names and does not manipulate the search path.

---

## pg\_config

pg\_config — retrieve information about the installed version of Postgres Pro

### Synopsis

```
pg_config [option...]
```

### Description

The `pg_config` utility prints configuration parameters of the currently installed version of Postgres Pro. It is intended, for example, to be used by software packages that want to interface to Postgres Pro to facilitate finding the required header files and libraries.

### Options

To use `pg_config`, supply one or more of the following options:

`--bindir`

Print the location of user executables. Use this, for example, to find the `psql` program. This is normally also the location where the `pg_config` program resides.

`--docdir`

Print the location of documentation files.

`--htmldir`

Print the location of HTML documentation files.

`--includedir`

Print the location of C header files of the client interfaces.

`--pkgincludedir`

Print the location of other C header files.

`--includedir-server`

Print the location of C header files for server programming.

`--libdir`

Print the location of object code libraries.

`--pkglibdir`

Print the location of dynamically loadable modules, or where the server would search for them. (Other architecture-dependent data files might also be installed in this directory.)

`--localedir`

Print the location of locale support files. (This will be an empty string if locale support was not configured when Postgres Pro was built.)

`--mandir`

Print the location of manual pages.

`--sharedir`

Print the location of architecture-independent support files.

`--sysconfdir`

Print the location of system-wide configuration files.

`--pgxs`

Print the location of extension makefiles.

`--configure`

Print the options that were given to the `configure` script when Postgres Pro was configured for building. This can be used to reproduce the identical configuration, or to find out with what options a binary package was built. (Note however that binary packages often contain vendor-specific custom patches.) See also the examples below.

`--cc`

Print the value of the `CC` variable that was used for building Postgres Pro. This shows the C compiler used.

`--cppflags`

Print the value of the `CPPFLAGS` variable that was used for building Postgres Pro. This shows C compiler switches needed at preprocessing time (typically, `-I` switches).

`--cflags`

Print the value of the `CFLAGS` variable that was used for building Postgres Pro. This shows C compiler switches.

`--cflags_sl`

Print the value of the `CFLAGS_SL` variable that was used for building Postgres Pro. This shows extra C compiler switches used for building shared libraries.

`--ldflags`

Print the value of the `LDFLAGS` variable that was used for building Postgres Pro. This shows linker switches.

`--ldflags_ex`

Print the value of the `LDFLAGS_EX` variable that was used for building Postgres Pro. This shows linker switches used for building executables only.

`--ldflags_sl`

Print the value of the `LDFLAGS_SL` variable that was used for building Postgres Pro. This shows linker switches used for building shared libraries only.

`--libs`

Print the value of the `LIBS` variable that was used for building Postgres Pro. This normally contains `-l` switches for external libraries linked into Postgres Pro.

`--version`

Print the PostgreSQL version on which Postgres Pro is based.

`--pgpro-version`

Print the version of Postgres Pro.

`--pgpro-edition`

Print the edition of Postgres Pro.

-?  
--help

Show help about pg\_config command line arguments, and exit.

If more than one option is given, the information is printed in that order, one item per line. If no options are given, all available information is printed, with labels.

## Notes

The options `--docdir`, `--pkgincludedir`, `--localedir`, `--mandir`, `--sharedir`, `--sysconfdir`, `--cc`, `--cppflags`, `--cflags`, `--cflags_sl`, `--ldflags`, `--ldflags_sl`, and `--libs` were added in PostgreSQL 8.1. The option `--htmldir` was added in PostgreSQL 8.4. The option `--ldflags_ex` was added in PostgreSQL 9.0.

## Example

To reproduce the build configuration of the current Postgres Pro installation, run the following command:

```
eval `./configure `pg_config --configure`
```

The output of `pg_config --configure` contains shell quotation marks so arguments with spaces are represented correctly. Therefore, using `eval` is required for proper results.

---

# pg\_dump

`pg_dump` — extract a Postgres Pro database into a script file or other archive file

## Synopsis

```
pg_dump [connection-option...] [option...] [dbname]
```

## Description

`pg_dump` is a utility for backing up a Postgres Pro database. It makes consistent backups even if the database is being used concurrently. `pg_dump` does not block other users accessing the database (readers or writers).

`pg_dump` only dumps a single database. To back up an entire cluster, or to back up global objects that are common to all databases in a cluster (such as roles and tablespaces), use [pg\\_dumpall](#).

Dumps can be output in script or archive file formats. Script dumps are plain-text files containing the SQL commands required to reconstruct the database to the state it was in at the time it was saved. To restore from such a script, feed it to [psql](#). Script files can be used to reconstruct the database even on other machines and other architectures; with some modifications, even on other SQL database products.

The alternative archive file formats must be used with [pg\\_restore](#) to rebuild the database. They allow `pg_restore` to be selective about what is restored, or even to reorder the items prior to being restored. The archive file formats are designed to be portable across architectures.

When used with one of the archive file formats and combined with `pg_restore`, `pg_dump` provides a flexible archival and transfer mechanism. `pg_dump` can be used to backup an entire database, then `pg_restore` can be used to examine the archive and/or select which parts of the database are to be restored. The most flexible output file formats are the “custom” format (`-Fc`) and the “directory” format (`-Fd`). They allow for selection and reordering of all archived items, support parallel restoration, and are compressed by default. The “directory” format is the only format that supports parallel dumps.

While running `pg_dump`, one should examine the output for any warnings (printed on standard error), especially in light of the limitations listed below.

## Options

The following command-line options control the content and format of the output.

*dbname*

Specifies the name of the database to be dumped. If this is not specified, the environment variable `PGDATABASE` is used. If that is not set, the user name specified for the connection is used.

`-a`

`--data-only`

Dump only the data, not the schema (data definitions). Table data, large objects, and sequence values are dumped.

This option is similar to, but for historical reasons not identical to, specifying `--section=data`.

`-b`

`--blobs`

Include large objects in the dump. This is the default behavior except when `--schema`, `--table`, or `--schema-only` is specified. The `-b` switch is therefore only useful to add large objects to dumps where

a specific schema or table has been requested. Note that blobs are considered data and therefore will be included when `--data-only` is used, but not when `--schema-only` is.

`-B`  
`--no-blobs`

Exclude large objects in the dump.

When both `-b` and `-B` are given, the behavior is to output large objects, when data is being dumped, see the `-b` documentation.

`-c`  
`--clean`

Output commands to clean (drop) database objects prior to outputting the commands for creating them. (Unless `--if-exists` is also specified, restore might generate some harmless error messages, if any objects were not present in the destination database.)

This option is ignored when emitting an archive (non-text) output file. For the archive formats, you can specify the option when you call `pg_restore`.

`-C`  
`--create`

Begin the output with a command to create the database itself and reconnect to the created database. (With a script of this form, it doesn't matter which database in the destination installation you connect to before running the script.) If `--clean` is also specified, the script drops and recreates the target database before reconnecting to it.

With `--create`, the output also includes the database's comment if any, and any configuration variable settings that are specific to this database, that is, any `ALTER DATABASE ... SET ...` and `ALTER ROLE ... IN DATABASE ... SET ...` commands that mention this database. Access privileges for the database itself are also dumped, unless `--no-acl` is specified.

This option is ignored when emitting an archive (non-text) output file. For the archive formats, you can specify the option when you call `pg_restore`.

`-E encoding`  
`--encoding=encoding`

Create the dump in the specified character set encoding. By default, the dump is created in the database encoding. (Another way to get the same result is to set the `PGCLIENTENCODING` environment variable to the desired dump encoding.)

`-f file`  
`--file=file`

Send output to the specified file. This parameter can be omitted for file based output formats, in which case the standard output is used. It must be given for the directory output format however, where it specifies the target directory instead of a file. In this case the directory is created by `pg_dump` and must not exist before.

`-F format`  
`--format=format`

Selects the format of the output. *format* can be one of the following:

`p`  
`plain`

Output a plain-text SQL script file (the default).

c  
custom

Output a custom-format archive suitable for input into `pg_restore`. Together with the directory output format, this is the most flexible output format in that it allows manual selection and reordering of archived items during restore. This format is also compressed by default.

d  
directory

Output a directory-format archive suitable for input into `pg_restore`. This will create a directory with one file for each table and blob being dumped, plus a so-called Table of Contents file describing the dumped objects in a machine-readable format that `pg_restore` can read. A directory format archive can be manipulated with standard Unix tools; for example, files in an uncompressed archive can be compressed with the `gzip` tool. This format is compressed by default and also supports parallel dumps.

t  
tar

Output a `tar`-format archive suitable for input into `pg_restore`. The `tar` format is compatible with the directory format: extracting a `tar`-format archive produces a valid directory-format archive. However, the `tar` format does not support compression. Also, when using `tar` format the relative order of table data items cannot be changed during restore.

`-j njobs`  
`--jobs=njobs`

Run the dump in parallel by dumping `njobs` tables simultaneously. This option may reduce the time needed to perform the dump but it also increases the load on the database server. You can only use this option with the directory output format because this is the only output format where multiple processes can write their data at the same time.

`pg_dump` will open `njobs + 1` connections to the database, so make sure your [max\\_connections](#) setting is high enough to accommodate all connections.

Requesting exclusive locks on database objects while running a parallel dump could cause the dump to fail. The reason is that the `pg_dump` master process requests shared locks on the objects that the worker processes are going to dump later in order to make sure that nobody deletes them and makes them go away while the dump is running. If another client then requests an exclusive lock on a table, that lock will not be granted but will be queued waiting for the shared lock of the master process to be released. Consequently any other access to the table will not be granted either and will queue after the exclusive lock request. This includes the worker process trying to dump the table. Without any precautions this would be a classic deadlock situation. To detect this conflict, the `pg_dump` worker process requests another shared lock using the `NOWAIT` option. If the worker process is not granted this shared lock, somebody else must have requested an exclusive lock in the meantime and there is no way to continue with the dump, so `pg_dump` has no choice but to abort the dump.

For a consistent backup, the database server needs to support synchronized snapshots, a feature that was introduced in PostgreSQL 9.2 for primary servers and 10 for standbys. With this feature, database clients can ensure they see the same data set even though they use different connections. `pg_dump -j` uses multiple database connections; it connects to the database once with the master process and once again for each worker job. Without the synchronized snapshot feature, the different worker jobs wouldn't be guaranteed to see the same data in each connection, which could lead to an inconsistent backup.

If you want to run a parallel dump of a pre-9.2 server, you need to make sure that the database content doesn't change from between the time the master connects to the database until the last worker job has connected to the database. The easiest way to do this is to halt any data modifying processes (DDL and DML) accessing the database before starting the backup. You also need to specify the `--no-synchronized-snapshots` parameter when running `pg_dump -j` against a pre-9.2 PostgreSQL server.

`-n pattern`  
`--schema=pattern`

Dump only schemas matching *pattern*; this selects both the schema itself, and all its contained objects. When this option is not specified, all non-system schemas in the target database will be dumped. Multiple schemas can be selected by writing multiple `-n` switches. The *pattern* parameter is interpreted as a pattern according to the same rules used by `psql`'s `\d` commands (see [Patterns](#) below), so multiple schemas can also be selected by writing wildcard characters in the pattern. When using wildcards, be careful to quote the pattern if needed to prevent the shell from expanding the wildcards; see [Examples](#) below.

### Note

When `-n` is specified, `pg_dump` makes no attempt to dump any other database objects that the selected schema(s) might depend upon. Therefore, there is no guarantee that the results of a specific-schema dump can be successfully restored by themselves into a clean database.

### Note

Non-schema objects such as blobs are not dumped when `-n` is specified. You can add blobs back to the dump with the `--blobs` switch.

`-N pattern`  
`--exclude-schema=pattern`

Do not dump any schemas matching *pattern*. The pattern is interpreted according to the same rules as for `-n`. `-N` can be given more than once to exclude schemas matching any of several patterns.

When both `-n` and `-N` are given, the behavior is to dump just the schemas that match at least one `-n` switch but no `-N` switches. If `-N` appears without `-n`, then schemas matching `-N` are excluded from what is otherwise a normal dump.

`-O`  
`--no-owner`

Do not output commands to set ownership of objects to match the original database. By default, `pg_dump` issues `ALTER OWNER` or `SET SESSION AUTHORIZATION` statements to set ownership of created database objects. These statements will fail when the script is run unless it is started by a superuser (or the same user that owns all of the objects in the script). To make a script that can be restored by any user, but will give that user ownership of all the objects, specify `-O`.

This option is ignored when emitting an archive (non-text) output file. For the archive formats, you can specify the option when you call `pg_restore`.

`-R`  
`--no-reconnect`

This option is obsolete but still accepted for backwards compatibility.

`-s`  
`--schema-only`

Dump only the object definitions (schema), not data.

This option is the inverse of `--data-only`. It is similar to, but for historical reasons not identical to, specifying `--section=pre-data --section=post-data`.

(Do not confuse this with the `--schema` option, which uses the word “schema” in a different meaning.)

To exclude table data for only a subset of tables in the database, see `--exclude-table-data`.

`-S username`  
`--superuser=username`

Specify the superuser user name to use when disabling triggers. This is relevant only if `--disable-triggers` is used. (Usually, it's better to leave this out, and instead start the resulting script as superuser.)

`-t pattern`  
`--table=pattern`

Dump only tables with names matching *pattern*. Multiple tables can be selected by writing multiple `-t` switches. The *pattern* parameter is interpreted as a pattern according to the same rules used by `psql`'s `\d` commands (see [Patterns](#) below), so multiple tables can also be selected by writing wildcard characters in the pattern. When using wildcards, be careful to quote the pattern if needed to prevent the shell from expanding the wildcards; see [Examples](#) below.

As well as tables, this option can be used to dump the definition of matching views, materialized views, foreign tables, and sequences. It will not dump the contents of views or materialized views, and the contents of foreign tables will only be dumped if the corresponding foreign server is specified with `--include-foreign-data`.

The `-n` and `-N` switches have no effect when `-t` is used, because tables selected by `-t` will be dumped regardless of those switches, and non-table objects will not be dumped.

### Note

When `-t` is specified, `pg_dump` makes no attempt to dump any other database objects that the selected table(s) might depend upon. Therefore, there is no guarantee that the results of a specific-table dump can be successfully restored by themselves into a clean database.

### Note

The behavior of the `-t` switch is not entirely upward compatible with pre-8.2 PostgreSQL versions. Formerly, writing `-t tab` would dump all tables named `tab`, but now it just dumps whichever one is visible in your default search path. To get the old behavior you can write `-t '*.tab'`. Also, you must write something like `-t sch.tab` to select a table in a particular schema, rather than the old locution of `-n sch -t tab`.

`-T pattern`  
`--exclude-table=pattern`

Do not dump any tables matching *pattern*. The pattern is interpreted according to the same rules as for `-t`. `-T` can be given more than once to exclude tables matching any of several patterns.

When both `-t` and `-T` are given, the behavior is to dump just the tables that match at least one `-t` switch but no `-T` switches. If `-T` appears without `-t`, then tables matching `-T` are excluded from what is otherwise a normal dump.

`-v`  
`--verbose`

Specifies verbose mode. This will cause `pg_dump` to output detailed object comments and start/stop times to the dump file, and progress messages to standard error.

`-V`  
`--version`

Print the `pg_dump` version and exit.

`-x`  
`--no-privileges`  
`--no-acl`

Prevent dumping of access privileges (grant/revoke commands).

`-Z 0..9`  
`--compress=0..9`

Specify the compression level to use. Zero means no compression. For the custom and directory archive formats, this specifies compression of individual table-data segments, and the default is to compress at a moderate level. For plain text output, setting a nonzero compression level causes the entire output file to be compressed, as though it had been fed through gzip; but the default is not to compress. The tar archive format currently does not support compression at all.

`--add-collprovider`

If the provider for the default collation of the database to be dumped is implicit, explicitly specifies this provider in the dump. This option is recommended if you are using `pg_dump` and `pg_restore` to upgrade from previous versions of Postgres Pro or any version of PostgreSQL. It allows to preserve the original provider of the default collation if the `template0` database in the new cluster uses different collation settings. Otherwise, check constraints that use the default collation may change and the `COPY` command may end with a failure. For binary upgrades, this option is used automatically.

`--binary-upgrade`

This option is for use by in-place upgrade utilities. Its use for other purposes is not recommended or supported. The behavior of the option may change in future releases without notice.

`--column-inserts`  
`--attribute-inserts`

Dump data as `INSERT` commands with explicit column names (`INSERT INTO table (column, ...) VALUES ...`). This will make restoration very slow; it is mainly useful for making dumps that can be loaded into non-Postgres Pro databases. Any error during reloading will cause only rows that are part of the problematic `INSERT` to be lost, rather than the entire table contents.

`--disable-dollar-quoting`

This option disables the use of dollar quoting for function bodies, and forces them to be quoted using SQL standard string syntax.

`--disable-triggers`

This option is relevant only when creating a data-only dump. It instructs `pg_dump` to include commands to temporarily disable triggers on the target tables while the data is reloaded. Use this if you have referential integrity checks or other triggers on the tables that you do not want to invoke during data reload.

Presently, the commands emitted for `--disable-triggers` must be done as superuser. So, you should also specify a superuser name with `-s`, or preferably be careful to start the resulting script as a superuser.

This option is ignored when emitting an archive (non-text) output file. For the archive formats, you can specify the option when you call `pg_restore`.

`--enable-row-security`

This option is relevant only when dumping the contents of a table which has row security. By default, `pg_dump` will set `row_security` to off, to ensure that all data is dumped from the table. If the user does not have sufficient privileges to bypass row security, then an error is thrown. This parameter instructs `pg_dump` to set `row_security` to on instead, allowing the user to dump the parts of the contents of the table that they have access to.

Note that if you use this option currently, you probably also want the dump be in `INSERT` format, as the `COPY FROM` during restore does not support row security.

`--exclude-table-data=pattern`

Do not dump data for any tables matching *pattern*. The pattern is interpreted according to the same rules as for `-t`. `--exclude-table-data` can be given more than once to exclude tables matching any of several patterns. This option is useful when you need the definition of a particular table even though you do not need the data in it.

To exclude data for all tables in the database, see `--schema-only`.

`--extra-float-digits=ndigits`

Use the specified value of `extra_float_digits` when dumping floating-point data, instead of the maximum available precision. Routine dumps made for backup purposes should not use this option.

`--if-exists`

Use conditional commands (i.e., add an `IF EXISTS` clause) when cleaning database objects. This option is not valid unless `--clean` is also specified.

`--include-foreign-data=foreignserver`

Dump the data for any foreign table with a foreign server matching *foreignserver* pattern. Multiple foreign servers can be selected by writing multiple `--include-foreign-data` switches. Also, the *foreignserver* parameter is interpreted as a pattern according to the same rules used by `psql`'s `\d` commands (see [Patterns](#) below), so multiple foreign servers can also be selected by writing wildcard characters in the pattern. When using wildcards, be careful to quote the pattern if needed to prevent the shell from expanding the wildcards; see [Examples](#) below. The only exception is that an empty pattern is disallowed.

### Note

When `--include-foreign-data` is specified, `pg_dump` does not check that the foreign table is writable. Therefore, there is no guarantee that the results of a foreign table dump can be successfully restored.

`--inserts`

Dump data as `INSERT` commands (rather than `COPY`). This will make restoration very slow; it is mainly useful for making dumps that can be loaded into non-Postgres Pro databases. Any error during reloading will cause only rows that are part of the problematic `INSERT` to be lost, rather than the entire table contents. Note that the restore might fail altogether if you have rearranged column order. The `--column-inserts` option is safe against column order changes, though even slower.

`--load-via-partition-root`

When dumping data for a table partition, make the `COPY` or `INSERT` statements target the root of the partitioning hierarchy that contains it, rather than the partition itself. This causes the appropriate partition to be re-determined for each row when the data is loaded. This may be useful when reloading data on a server where rows do not always fall into the same partitions as they did on the original server. That could happen, for example, if the partitioning column is of type `text` and the two systems have different definitions of the collation used to sort the partitioning column.

It is best not to use parallelism when restoring from an archive made with this option, because `pg_restore` will not know exactly which partition(s) a given archive data item will load data into. This could result in inefficiency due to lock conflicts between parallel jobs, or perhaps even reload failures due to foreign key constraints being set up before all the relevant data is loaded.

`--lock-wait-timeout=timeout`

Do not wait forever to acquire shared table locks at the beginning of the dump. Instead fail if unable to lock a table within the specified *timeout*. The timeout may be specified in any of the formats accepted by `SET statement_timeout`. (Allowed formats vary depending on the server version you are dumping from, but an integer number of milliseconds is accepted by all versions.)

`--no-comments`

Do not dump comments.

`--no-publications`

Do not dump publications.

`--no-security-labels`

Do not dump security labels.

`--no-subscriptions`

Do not dump subscriptions.

`--no-sync`

By default, `pg_dump` will wait for all files to be written safely to disk. This option causes `pg_dump` to return without waiting, which is faster, but means that a subsequent operating system crash can leave the dump corrupt. Generally, this option is useful for testing but should not be used when dumping data from production installation.

`--no-synchronized-snapshots`

This option allows running `pg_dump -j` against a pre-9.2 server, see the documentation of the `-j` parameter for more details.

`--no-tablespaces`

Do not output commands to select tablespaces. With this option, all objects will be created in whichever tablespace is the default during restore.

This option is ignored when emitting an archive (non-text) output file. For the archive formats, you can specify the option when you call `pg_restore`.

`--no-unlogged-table-data`

Do not dump the contents of unlogged tables. This option has no effect on whether or not the table definitions (schema) are dumped; it only suppresses dumping the table data. Data in unlogged tables is always excluded when dumping from a standby server.

`--on-conflict-do-nothing`

Add `ON CONFLICT DO NOTHING` to `INSERT` commands. This option is not valid unless `--inserts`, `--column-inserts` or `--rows-per-insert` is also specified.

`--quote-all-identifiers`

Force quoting of all identifiers. This option is recommended when dumping a database from a server whose PostgreSQL major version is different from `pg_dump`'s, or when the output is intended to be loaded into a server of a different major version. By default, `pg_dump` quotes only identifiers that are reserved words in its own major version. This sometimes results in compatibility issues when dealing with servers of other versions that may have slightly different sets of reserved words. Using `--quote-all-identifiers` prevents such issues, at the price of a harder-to-read dump script.

`--rows-per-insert=nrows`

Dump data as `INSERT` commands (rather than `COPY`). Controls the maximum number of rows per `INSERT` command. The value specified must be a number greater than zero. Any error during

reloading will cause only rows that are part of the problematic `INSERT` to be lost, rather than the entire table contents.

`--section=sectionname`

Only dump the named section. The section name can be `pre-data`, `data`, or `post-data`. This option can be specified more than once to select multiple sections. The default is to dump all sections.

The data section contains actual table data, large-object contents, and sequence values. Post-data items include definitions of indexes, triggers, rules, and constraints other than validated check constraints. Pre-data items include all other data definition items.

`--serializable-deferrable`

Use a `serializable` transaction for the dump, to ensure that the snapshot used is consistent with later database states; but do this by waiting for a point in the transaction stream at which no anomalies can be present, so that there isn't a risk of the dump failing or causing other transactions to roll back with a `serialization_failure`. See [Chapter 13](#) for more information about transaction isolation and concurrency control.

This option is not beneficial for a dump which is intended only for disaster recovery. It could be useful for a dump used to load a copy of the database for reporting or other read-only load sharing while the original database continues to be updated. Without it the dump may reflect a state which is not consistent with any serial execution of the transactions eventually committed. For example, if batch processing techniques are used, a batch may show as closed in the dump without all of the items which are in the batch appearing.

This option will make no difference if there are no read-write transactions active when `pg_dump` is started. If read-write transactions are active, the start of the dump may be delayed for an indeterminate length of time. Once running, performance with or without the switch is the same.

`--snapshot=snapshotname`

Use the specified synchronized snapshot when making a dump of the database (see [Table 9.88](#) for more details).

This option is useful when needing to synchronize the dump with a logical replication slot (see [Chapter 46](#)) or with a concurrent session.

In the case of a parallel dump, the snapshot name defined by this option is used rather than taking a new snapshot.

`--strict-names`

Require that each schema (`-n/--schema`) and table (`-t/--table`) qualifier match at least one schema/table in the database to be dumped. Note that if none of the schema/table qualifiers find matches, `pg_dump` will generate an error even without `--strict-names`.

This option has no effect on `-N/--exclude-schema`, `-T/--exclude-table`, or `--exclude-table-data`. An exclude pattern failing to match any objects is not considered an error.

`--use-set-session-authorization`

Output SQL-standard `SET SESSION AUTHORIZATION` commands instead of `ALTER OWNER` commands to determine object ownership. This makes the dump more standards-compatible, but depending on the history of the objects in the dump, might not restore properly. Also, a dump using `SET SESSION AUTHORIZATION` will certainly require superuser privileges to restore correctly, whereas `ALTER OWNER` requires lesser privileges.

`-?`

`--help`

Show help about `pg_dump` command line arguments, and exit.

The following command-line options control the database connection parameters.

`-d dbname`

`--dbname=dbname`

Specifies the name of the database to connect to. This is equivalent to specifying *dbname* as the first non-option argument on the command line. The *dbname* can be a [connection string](#). If so, connection string parameters will override any conflicting command line options.

`-h host`

`--host=host`

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket. The default is taken from the `PGHOST` environment variable, if set, else a Unix domain socket connection is attempted.

`-p port`

`--port=port`

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections. Defaults to the `PGPORT` environment variable, if set, or a compiled-in default.

`-U username`

`--username=username`

User name to connect as.

`-w`

`--no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`

`--password`

Force `pg_dump` to prompt for a password before connecting to a database.

This option is never essential, since `pg_dump` will automatically prompt for a password if the server demands password authentication. However, `pg_dump` will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-w` to avoid the extra connection attempt.

`--role=rolename`

Specifies a role name to be used to create the dump. This option causes `pg_dump` to issue a `SET ROLE rolename` command after connecting to the database. It is useful when the authenticated user (specified by `-U`) lacks privileges needed by `pg_dump`, but can switch to a role with the required rights. Some installations have a policy against logging in directly as a superuser, and use of this option allows dumps to be made without violating the policy.

## Environment

`PGDATABASE`

`PGHOST`

`PGOPTIONS`

`PGPORT`

`PGUSER`

Default connection parameters.

`PG_COLOR`

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by libpq (see [Section 31.14](#)).

## Diagnostics

`pg_dump` internally executes `SELECT` statements. If you have problems running `pg_dump`, make sure you are able to select information from the database using, for example, `psql`. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

The database activity of `pg_dump` is normally collected by the statistics collector. If this is undesirable, you can set parameter `track_counts` to `false` via `PGOPTIONS` or the `ALTER USER` command.

## Notes

If your database cluster has any local additions to the `template1` database, be careful to restore the output of `pg_dump` into a truly empty database; otherwise you are likely to get errors due to duplicate definitions of the added objects. To make an empty database without any local additions, copy from `template0` not `template1`, for example:

```
CREATE DATABASE foo WITH TEMPLATE template0;
```

When a data-only dump is chosen and the option `--disable-triggers` is used, `pg_dump` emits commands to disable triggers on user tables before inserting the data, and then commands to re-enable them after the data has been inserted. If the restore is stopped in the middle, the system catalogs might be left in the wrong state.

The dump file produced by `pg_dump` does not contain the statistics used by the optimizer to make query planning decisions. Therefore, it is wise to run `ANALYZE` after restoring from a dump file to ensure optimal performance; see [Section 23.1.3](#) and [Section 23.1.6](#) for more information.

Because `pg_dump` is used to transfer data to newer versions of Postgres Pro, the output of `pg_dump` can be expected to load into Postgres Pro server versions newer than `pg_dump`'s version. `pg_dump` can also dump from Postgres Pro servers older than its own version. (Currently, servers back to version 8.0 are supported.) However, `pg_dump` cannot dump from Postgres Pro servers newer than its own major version; it will refuse to even try, rather than risk making an invalid dump. Also, it is not guaranteed that `pg_dump`'s output can be loaded into a server of an older major version — not even if the dump was taken from a server of that version. Loading a dump file into an older server may require manual editing of the dump file to remove syntax not understood by the older server. Use of the `--quote-all-identifiers` option is recommended in cross-version cases, as it can prevent problems arising from varying reserved-word lists in different PostgreSQL versions.

When dumping logical replication subscriptions, `pg_dump` will generate `CREATE SUBSCRIPTION` commands that use the `connect = false` option, so that restoring the subscription does not make remote connections for creating a replication slot or for initial table copy. That way, the dump can be restored without requiring network access to the remote servers. It is then up to the user to reactivate the subscriptions in a suitable way. If the involved hosts have changed, the connection information might have to be changed. It might also be appropriate to truncate the target tables before initiating a new full table copy.

## Examples

To dump a database called `mydb` into a SQL-script file:

```
$ pg_dump mydb > db.sql
```

To reload such a script into a (freshly created) database named `newdb`:

```
$ psql -d newdb -f db.sql
```

To dump a database into a custom-format archive file:

```
$ pg_dump -Fc mydb > db.dump
```

To dump a database into a directory-format archive:

```
$ pg_dump -Fd mydb -f dumpdir
```

To dump a database into a directory-format archive in parallel with 5 worker jobs:

```
$ pg_dump -Fd mydb -j 5 -f dumpdir
```

To reload an archive file into a (freshly created) database named `newdb`:

```
$ pg_restore -d newdb db.dump
```

To reload an archive file into the same database it was dumped from, discarding the current contents of that database:

```
$ pg_restore -d postgres --clean --create db.dump
```

To dump a single table named `mytab`:

```
$ pg_dump -t mytab mydb > db.sql
```

To dump all tables whose names start with `emp` in the `detroit` schema, except for the table named `employee_log`:

```
$ pg_dump -t 'detroit.emp*' -T detroit.employee_log mydb > db.sql
```

To dump all schemas whose names start with `east` or `west` and end in `gsm`, excluding any schemas whose names contain the word `test`:

```
$ pg_dump -n 'east*gsm' -n 'west*gsm' -N '*test*' mydb > db.sql
```

The same, using regular expression notation to consolidate the switches:

```
$ pg_dump -n '(east|west)*gsm' -N '*test*' mydb > db.sql
```

To dump all database objects except for tables whose names begin with `ts_`:

```
$ pg_dump -T 'ts_*' mydb > db.sql
```

To specify an upper-case or mixed-case name in `-t` and related switches, you need to double-quote the name; else it will be folded to lower case (see [Patterns](#) below). But double quotes are special to the shell, so in turn they must be quoted. Thus, to dump a single table with a mixed-case name, you need something like

```
$ pg_dump -t "\"MixedCaseName\"" mydb > mytab.sql
```

# pg\_dumpall

`pg_dumpall` — extract a Postgres Pro database cluster into a script file

## Synopsis

```
pg_dumpall [connection-option...] [option...]
```

## Description

`pg_dumpall` is a utility for writing out (“dumping”) all Postgres Pro databases of a cluster into one script file. The script file contains SQL commands that can be used as input to `psql` to restore the databases. It does this by calling `pg_dump` for each database in the cluster. `pg_dumpall` also dumps global objects that are common to all databases, that is, database roles and tablespaces. (`pg_dump` does not save these objects.)

Since `pg_dumpall` reads tables from all databases you will most likely have to connect as a database superuser in order to produce a complete dump. Also you will need superuser privileges to execute the saved script in order to be allowed to add roles and create databases.

The SQL script will be written to the standard output. Use the `-f/--file` option or shell operators to redirect it into a file.

`pg_dumpall` needs to connect several times to the Postgres Pro server (once per database). If you use password authentication it will ask for a password each time. It is convenient to have a `~/.pgpass` file in such cases. See [Section 31.15](#) for more information.

## Options

The following command-line options control the content and format of the output.

- `-a`  
`--data-only`  
Dump only the data, not the schema (data definitions).
- `-c`  
`--clean`  
Include SQL commands to clean (drop) databases before recreating them. `DROP` commands for roles and tablespaces are added as well.
- `-E encoding`  
`--encoding=encoding`  
Create the dump in the specified character set encoding. By default, the dump is created in the database encoding. (Another way to get the same result is to set the `PGCLIENTENCODING` environment variable to the desired dump encoding.)
- `-f filename`  
`--file=filename`  
Send output to the specified file. If this is omitted, the standard output is used.
- `-g`  
`--globals-only`  
Dump only global objects (roles and tablespaces), no databases.
- `-O`  
`--no-owner`  
Do not output commands to set ownership of objects to match the original database. By default, `pg_dumpall` issues `ALTER OWNER` or `SET SESSION AUTHORIZATION` statements to set ownership of

created schema elements. These statements will fail when the script is run unless it is started by a superuser (or the same user that owns all of the objects in the script). To make a script that can be restored by any user, but will give that user ownership of all the objects, specify `-O`.

`-r`  
`--roles-only`  
Dump only roles, no databases or tablespaces.

`-s`  
`--schema-only`  
Dump only the object definitions (schema), not data.

`-S username`  
`--superuser=username`  
Specify the superuser user name to use when disabling triggers. This is relevant only if `--disable-triggers` is used. (Usually, it's better to leave this out, and instead start the resulting script as superuser.)

`-t`  
`--tablespaces-only`  
Dump only tablespaces, no databases or roles.

`-v`  
`--verbose`  
Specifies verbose mode. This will cause `pg_dumpall` to output start/stop times to the dump file, and progress messages to standard error. It will also enable verbose output in `pg_dump`.

`-V`  
`--version`  
Print the `pg_dumpall` version and exit.

`-x`  
`--no-privileges`  
`--no-acl`  
Prevent dumping of access privileges (grant/revoke commands).

`--add-collprovider`  
If the provider for the default collation of the database to be dumped is implicit, explicitly specifies this provider in the dump. This option is recommended if you are using `pg_dumpall` and `pg_restore` to upgrade from previous versions of Postgres Pro or any version of PostgreSQL. It allows to preserve the original provider of the default collation if the `template0` database in the new cluster uses different collation settings. Otherwise, check constraints that use the default collation may change and the `COPY` command may end with a failure. For binary upgrades, this option is used automatically.

`--binary-upgrade`  
This option is for use by in-place upgrade utilities. Its use for other purposes is not recommended or supported. The behavior of the option may change in future releases without notice.

`--column-inserts`  
`--attribute-inserts`  
Dump data as `INSERT` commands with explicit column names (`INSERT INTO table (column, ...) VALUES ...`). This will make restoration very slow; it is mainly useful for making dumps that can be loaded into non-Postgres Pro databases.

`--disable-dollar-quoting`

This option disables the use of dollar quoting for function bodies, and forces them to be quoted using SQL standard string syntax.

`--disable-triggers`

This option is relevant only when creating a data-only dump. It instructs `pg_dumpall` to include commands to temporarily disable triggers on the target tables while the data is reloaded. Use this if you have referential integrity checks or other triggers on the tables that you do not want to invoke during data reload.

Presently, the commands emitted for `--disable-triggers` must be done as superuser. So, you should also specify a superuser name with `-S`, or preferably be careful to start the resulting script as a superuser.

`--exclude-database=pattern`

Do not dump databases whose name matches *pattern*. Multiple patterns can be excluded by writing multiple `--exclude-database` switches. The *pattern* parameter is interpreted as a pattern according to the same rules used by `psql`'s `\d` commands (see [Patterns](#) below), so multiple databases can also be excluded by writing wildcard characters in the pattern. When using wildcards, be careful to quote the pattern if needed to prevent shell wildcard expansion.

`--extra-float-digits=ndigits`

Use the specified value of `extra_float_digits` when dumping floating-point data, instead of the maximum available precision. Routine dumps made for backup purposes should not use this option.

`--if-exists`

Use conditional commands (i.e., add an `IF EXISTS` clause) to drop databases and other objects. This option is not valid unless `--clean` is also specified.

`--inserts`

Dump data as `INSERT` commands (rather than `COPY`). This will make restoration very slow; it is mainly useful for making dumps that can be loaded into non-Postgres Pro databases. Note that the restore might fail altogether if you have rearranged column order. The `--column-inserts` option is safer, though even slower.

`--load-via-partition-root`

When dumping data for a table partition, make the `COPY` or `INSERT` statements target the root of the partitioning hierarchy that contains it, rather than the partition itself. This causes the appropriate partition to be re-determined for each row when the data is loaded. This may be useful when reloading data on a server where rows do not always fall into the same partitions as they did on the original server. That could happen, for example, if the partitioning column is of type `text` and the two systems have different definitions of the collation used to sort the partitioning column.

`--lock-wait-timeout=timeout`

Do not wait forever to acquire shared table locks at the beginning of the dump. Instead, fail if unable to lock a table within the specified *timeout*. The *timeout* may be specified in any of the formats accepted by `SET statement_timeout`. Allowed values vary depending on the server version you are dumping from, but an integer number of milliseconds is accepted by all versions since 7.3. This option is ignored when dumping from a pre-7.3 server.

`--no-comments`

Do not dump comments.

`--no-publications`

Do not dump publications.

`--no-role-passwords`

Do not dump passwords for roles. When restored, roles will have a null password, and password authentication will always fail until the password is set. Since password values aren't needed when this option is specified, the role information is read from the catalog view `pg_roles` instead of `pg_authid`. Therefore, this option also helps if access to `pg_authid` is restricted by some security policy.

`--no-security-labels`

Do not dump security labels.

`--no-subscriptions`

Do not dump subscriptions.

`--no-sync`

By default, `pg_dumpall` will wait for all files to be written safely to disk. This option causes `pg_dumpall` to return without waiting, which is faster, but means that a subsequent operating system crash can leave the dump corrupt. Generally, this option is useful for testing but should not be used when dumping data from production installation.

`--no-tablespaces`

Do not output commands to create tablespaces nor select tablespaces for objects. With this option, all objects will be created in whichever tablespace is the default during restore.

`--no-unlogged-table-data`

Do not dump the contents of unlogged tables. This option has no effect on whether or not the table definitions (schema) are dumped; it only suppresses dumping the table data.

`--on-conflict-do-nothing`

Add `ON CONFLICT DO NOTHING` to `INSERT` commands. This option is not valid unless `--inserts` or `--column-inserts` is also specified.

`--quote-all-identifiers`

Force quoting of all identifiers. This option is recommended when dumping a database from a server whose PostgreSQL major version is different from `pg_dumpall`'s, or when the output is intended to be loaded into a server of a different major version. By default, `pg_dumpall` quotes only identifiers that are reserved words in its own major version. This sometimes results in compatibility issues when dealing with servers of other versions that may have slightly different sets of reserved words. Using `--quote-all-identifiers` prevents such issues, at the price of a harder-to-read dump script.

`--rows-per-insert=nrows`

Dump data as `INSERT` commands (rather than `COPY`). Controls the maximum number of rows per `INSERT` command. The value specified must be a number greater than zero. Any error during reloading will cause only rows that are part of the problematic `INSERT` to be lost, rather than the entire table contents.

`--use-set-session-authorization`

Output SQL-standard `SET SESSION AUTHORIZATION` commands instead of `ALTER OWNER` commands to determine object ownership. This makes the dump more standards compatible, but depending on the history of the objects in the dump, might not restore properly.

`-?`

`--help`

Show help about `pg_dumpall` command line arguments, and exit.

The following command-line options control the database connection parameters.

`-d connstr`  
`--dbname=connstr`

Specifies parameters used to connect to the server, as a [connection string](#); these will override any conflicting command line options.

The option is called `--dbname` for consistency with other client applications, but because `pg_dumpall` needs to connect to many databases, the database name in the connection string will be ignored. Use the `-l` option to specify the name of the database used for the initial connection, which will dump global objects and discover what other databases should be dumped.

`-h host`  
`--host=host`

Specifies the host name of the machine on which the database server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket. The default is taken from the `PGHOST` environment variable, if set, else a Unix domain socket connection is attempted.

`-l dbname`  
`--database=dbname`

Specifies the name of the database to connect to for dumping global objects and discovering what other databases should be dumped. If not specified, the `postgres` database will be used, and if that does not exist, `template1` will be used.

`-p port`  
`--port=port`

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections. Defaults to the `PGPORT` environment variable, if set, or a compiled-in default.

`-U username`  
`--username=username`

User name to connect as.

`-w`  
`--no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`  
`--password`

Force `pg_dumpall` to prompt for a password before connecting to a database.

This option is never essential, since `pg_dumpall` will automatically prompt for a password if the server demands password authentication. However, `pg_dumpall` will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-w` to avoid the extra connection attempt.

Note that the password prompt will occur again for each database to be dumped. Usually, it's better to set up a `~/pgpass` file than to rely on manual password entry.

`--role=rolename`

Specifies a role name to be used to create the dump. This option causes `pg_dumpall` to issue a `SET ROLE rolename` command after connecting to the database. It is useful when the authenticated user (specified by `-U`) lacks privileges needed by `pg_dumpall`, but can switch to a role with the required

rights. Some installations have a policy against logging in directly as a superuser, and use of this option allows dumps to be made without violating the policy.

## Environment

PGHOST  
PGOPTIONS  
PGPORT  
PGUSER

Default connection parameters

PG\_COLOR

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by libpq (see [Section 31.14](#)).

## Notes

Since `pg_dumpall` calls `pg_dump` internally, some diagnostic messages will refer to `pg_dump`.

The `--clean` option can be useful even when your intention is to restore the dump script into a fresh cluster. Use of `--clean` authorizes the script to drop and re-create the built-in `postgres` and `template1` databases, ensuring that those databases will retain the same properties (for instance, locale and encoding) that they had in the source cluster. Without the option, those databases will retain their existing database-level properties, as well as any pre-existing contents.

Once restored, it is wise to run `ANALYZE` on each database so the optimizer has useful statistics. You can also run `vacuumdb -a -z` to analyze all databases.

The dump script should not be expected to run completely without errors. In particular, because the script will issue `CREATE ROLE` for every role existing in the source cluster, it is certain to get a “role already exists” error for the bootstrap superuser, unless the destination cluster was initialized with a different bootstrap superuser name. This error is harmless and should be ignored. Use of the `--clean` option is likely to produce additional harmless error messages about non-existent objects, although you can minimize those by adding `--if-exists`.

`pg_dumpall` requires all needed tablespace directories to exist before the restore; otherwise, database creation will fail for databases in non-default locations.

## Examples

To dump all databases:

```
$ pg_dumpall > db.out
```

To reload database(s) from this file, you can use:

```
$ psql -f db.out postgres
```

It is not important to which database you connect here since the script file created by `pg_dumpall` will contain the appropriate commands to create and connect to the saved databases. An exception is that if you specified `--clean`, you must connect to the `postgres` database initially; the script will attempt to drop other databases immediately, and that will fail for the database you are connected to.

## See Also

Check [pg\\_dump](#) for details on possible error conditions.

---

# pg\_isready

pg\_isready — check the connection status of a Postgres Pro server

## Synopsis

```
pg_isready [connection-option...] [option...]
```

## Description

pg\_isready is a utility for checking the connection status of a Postgres Pro database server. The exit status specifies the result of the connection check.

## Options

```
-d dbname  
--dbname=dbname
```

Specifies the name of the database to connect to. The *dbname* can be a [connection string](#). If so, connection string parameters will override any conflicting command line options.

```
-h hostname  
--host=hostname
```

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix-domain socket.

```
-p port  
--port=port
```

Specifies the TCP port or the local Unix-domain socket file extension on which the server is listening for connections. Defaults to the value of the `PGPORT` environment variable or, if not set, to the port specified at compile time, usually 5432.

```
-q  
--quiet
```

Do not display status message. This is useful when scripting.

```
-t seconds  
--timeout=seconds
```

The maximum number of seconds to wait when attempting connection before returning that the server is not responding. Setting to 0 disables. The default is 3 seconds.

```
-U username  
--username=username
```

Connect to the database as the user *username* instead of the default.

```
-V  
--version
```

Print the pg\_isready version and exit.

```
-?  
--help
```

Show help about pg\_isready command line arguments, and exit.

## Exit Status

`pg_isready` returns 0 to the shell if the server is accepting connections normally, 1 if the server is rejecting connections (for example during startup), 2 if there was no response to the connection attempt, and 3 if no attempt was made (for example due to invalid parameters).

## Environment

`pg_isready`, like most other Postgres Pro utilities, also uses the environment variables supported by `libpq` (see [Section 31.14](#)).

The environment variable `PG_COLOR` specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

## Notes

It is not necessary to supply correct user name, password, or database name values to obtain the server status; however, if incorrect values are provided, the server will log a failed connection attempt.

## Examples

Standard Usage:

```
$ pg_isready  
/tmp:5432 - accepting connections  
$ echo $?  
0
```

Running with connection parameters to a Postgres Pro cluster in startup:

```
$ pg_isready -h localhost -p 5433  
localhost:5433 - rejecting connections  
$ echo $?  
1
```

Running with connection parameters to a non-responsive Postgres Pro cluster:

```
$ pg_isready -h someremotehost  
someremotehost:5432 - no response  
$ echo $?  
2
```

---

# pg\_receivewal

pg\_receivewal — stream write-ahead logs from a Postgres Pro server

## Synopsis

```
pg_receivewal [option...]
```

## Description

pg\_receivewal is used to stream the write-ahead log from a running Postgres Pro cluster. The write-ahead log is streamed using the streaming replication protocol, and is written to a local directory of files. This directory can be used as the archive location for doing a restore using point-in-time recovery (see [Section 24.3](#)).

pg\_receivewal streams the write-ahead log in real time as it's being generated on the server, and does not wait for segments to complete like [archive\\_command](#) does. For this reason, it is not necessary to set [archive\\_timeout](#) when using pg\_receivewal.

Unlike the WAL receiver of a Postgres Pro standby server, pg\_receivewal by default flushes WAL data only when a WAL file is closed. The option `--synchronous` must be specified to flush WAL data in real time. Since pg\_receivewal does not apply WAL, you should not allow it to become a synchronous standby when [synchronous\\_commit](#) equals `remote_apply`. If it does, it will appear to be a standby that never catches up, and will cause transaction commits to block. To avoid this, you should either configure an appropriate value for [synchronous\\_standby\\_names](#), or specify `application_name` for pg\_receivewal that does not match it, or change the value of `synchronous_commit` to something other than `remote_apply`.

The write-ahead log is streamed over a regular Postgres Pro connection and uses the replication protocol. The connection must be made with a user having `REPLICATION` permissions (see [Section 20.2](#)) or a superuser, and `pg_hba.conf` must permit the replication connection. The server must also be configured with [max\\_wal\\_senders](#) set high enough to leave at least one session available for the stream.

The starting point of the write-ahead log streaming is calculated when pg\_receivewal starts:

1. First, scan the directory where the WAL segment files are written and find the newest completed segment file, using as the starting point the beginning of the next WAL segment file.
2. If a starting point cannot be calculated with the previous method, the latest WAL flush location is used as reported by the server from an `IDENTIFY_SYSTEM` command.

If the connection is lost, or if it cannot be initially established, with a non-fatal error, pg\_receivewal will retry the connection indefinitely, and reestablish streaming as soon as possible. To avoid this behavior, use the `-n` parameter.

In the absence of fatal errors, pg\_receivewal will run until terminated by the SIGINT signal (**Control+C**).

## Options

```
-D directory
```

```
--directory=directory
```

Directory to write the output to.

This parameter is required.

```
-E lsn
```

```
--endpos=lsn
```

Automatically stop replication and exit with normal exit status 0 when receiving reaches the specified LSN.

If there is a record with LSN exactly equal to *lsn*, the record will be processed.

`--if-not-exists`

Do not error out when `--create-slot` is specified and a slot with the specified name already exists.

`-n`

`--no-loop`

Don't loop on connection errors. Instead, exit right away with an error.

`--no-sync`

This option causes `pg_receivewal` to not force WAL data to be flushed to disk. This is faster, but means that a subsequent operating system crash can leave the WAL segments corrupt. Generally, this option is useful for testing but should not be used when doing WAL archiving on a production deployment.

This option is incompatible with `--synchronous`.

`-s interval`

`--status-interval=interval`

Specifies the number of seconds between status packets sent back to the server. This allows for easier monitoring of the progress from server. A value of zero disables the periodic status updates completely, although an update will still be sent when requested by the server, to avoid timeout disconnect. The default value is 10 seconds.

`-S slotname`

`--slot=slotname`

Require `pg_receivewal` to use an existing replication slot (see [Section 25.2.6](#)). When this option is used, `pg_receivewal` will report a flush position to the server, indicating when each segment has been synchronized to disk so that the server can remove that segment if it is not otherwise needed.

When the replication client of `pg_receivewal` is configured on the server as a synchronous standby, then using a replication slot will report the flush position to the server, but only when a WAL file is closed. Therefore, that configuration will cause transactions on the primary to wait for a long time and effectively not work satisfactorily. The option `--synchronous` (see below) must be specified in addition to make this work correctly.

`--synchronous`

Flush the WAL data to disk immediately after it has been received. Also send a status packet back to the server immediately after flushing, regardless of `--status-interval`.

This option should be specified if the replication client of `pg_receivewal` is configured on the server as a synchronous standby, to ensure that timely feedback is sent to the server.

`-v`

`--verbose`

Enables verbose mode.

`-Z level`

`--compress=level`

Enables gzip compression of write-ahead logs, and specifies the compression level (0 through 9, 0 being no compression and 9 being best compression). The suffix `.gz` will automatically be added to all filenames.

The following command-line options control the database connection parameters.

`-d connstr`  
`--dbname=connstr`

Specifies parameters used to connect to the server, as a [connection string](#); these will override any conflicting command line options.

The option is called `--dbname` for consistency with other client applications, but because `pg_receivewal` doesn't connect to any particular database in the cluster, database name in the connection string will be ignored.

`-h host`  
`--host=host`

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket. The default is taken from the `PGHOST` environment variable, if set, else a Unix domain socket connection is attempted.

`-p port`  
`--port=port`

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections. Defaults to the `PGPORT` environment variable, if set, or a compiled-in default.

`-U username`  
`--username=username`

User name to connect as.

`-w`  
`--no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`  
`--password`

Force `pg_receivewal` to prompt for a password before connecting to a database.

This option is never essential, since `pg_receivewal` will automatically prompt for a password if the server demands password authentication. However, `pg_receivewal` will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-w` to avoid the extra connection attempt.

`pg_receivewal` can perform one of the two following actions in order to control physical replication slots:

`--create-slot`

Create a new physical replication slot with the name specified in `--slot`, then exit.

`--drop-slot`

Drop the replication slot with the name specified in `--slot`, then exit.

Other options are also available:

`-V`  
`--version`

Print the `pg_receivewal` version and exit.

`-?`  
`--help`

Show help about `pg_receivewal` command line arguments, and exit.

## Exit Status

`pg_receivewal` will exit with status 0 when terminated by the SIGINT signal. (That is the normal way to end it. Hence it is not an error.) For fatal errors or other signals, the exit status will be nonzero.

## Environment

This utility, like most other Postgres Pro utilities, uses the environment variables supported by libpq (see [Section 31.14](#)).

The environment variable `PG_COLOR` specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

## Notes

When using `pg_receivewal` instead of [archive\\_command](#) as the main WAL backup method, it is strongly recommended to use replication slots. Otherwise, the server is free to recycle or remove write-ahead log files before they are backed up, because it does not have any information, either from [archive\\_command](#) or the replication slots, about how far the WAL stream has been archived. Note, however, that a replication slot will fill up the server's disk space if the receiver does not keep up with fetching the WAL data.

`pg_receivewal` will preserve group permissions on the received WAL files if group permissions are enabled on the source cluster.

## Examples

To stream the write-ahead log from the server at `mydbserver` and store it in the local directory `/usr/local/pgsql/archive`:

```
$ pg_receivewal -h mydbserver -D /usr/local/pgsql/archive
```

# pg\_recvlogical

pg\_recvlogical — control Postgres Pro logical decoding streams

## Synopsis

pg\_recvlogical [*option...*]

## Description

pg\_recvlogical controls logical decoding replication slots and streams data from such replication slots.

It creates a replication-mode connection, so it is subject to the same constraints as [pg\\_receivewal](#), plus those for logical replication (see [Chapter 46](#)).

pg\_recvlogical has no equivalent to the logical decoding SQL interface's peek and get modes. It sends replay confirmations for data lazily as it receives it and on clean exit. To examine pending data on a slot without consuming it, use [pg\\_logical\\_slot\\_peek\\_changes](#).

## Options

At least one of the following options must be specified to select an action:

`--create-slot`

Create a new logical replication slot with the name specified by `--slot`, using the output plugin specified by `--plugin`, for the database specified by `--dbname`.

`--drop-slot`

Drop the replication slot with the name specified by `--slot`, then exit.

`--start`

Begin streaming changes from the logical replication slot specified by `--slot`, continuing until terminated by a signal. If the server side change stream ends with a server shutdown or disconnect, retry in a loop unless `--no-loop` is specified.

The stream format is determined by the output plugin specified when the slot was created.

The connection must be to the same database used to create the slot.

`--create-slot` and `--start` can be specified together. `--drop-slot` cannot be combined with another action.

The following command-line options control the location and format of the output and other replication behavior:

`-E lsn`

`--endpos=lsn`

In `--start` mode, automatically stop replication and exit with normal exit status 0 when receiving reaches the specified LSN. If specified when not in `--start` mode, an error is raised.

If there's a record with LSN exactly equal to `lsn`, the record will be output.

The `--endpos` option is not aware of transaction boundaries and may truncate output partway through a transaction. Any partially output transaction will not be consumed and will be replayed again when the slot is next read from. Individual messages are never truncated.

`-f filename`

`--file=filename`

Write received and decoded transaction data into this file. Use `-` for stdout.

`-F interval_seconds`  
`--fsync-interval=interval_seconds`

Specifies how often `pg_recvlogical` should issue `fsync()` calls to ensure the output file is safely flushed to disk.

The server will occasionally request the client to perform a flush and report the flush position to the server. This setting is in addition to that, to perform flushes more frequently.

Specifying an interval of 0 disables issuing `fsync()` calls altogether, while still reporting progress to the server. In this case, data could be lost in the event of a crash.

`-I lsn`  
`--startpos=lsn`

In `--start` mode, start replication from the given LSN. For details on the effect of this, see the documentation in [Chapter 46](#) and [Section 50.4](#). Ignored in other modes.

`--if-not-exists`

Do not error out when `--create-slot` is specified and a slot with the specified name already exists.

`-n`  
`--no-loop`

When the connection to the server is lost, do not retry in a loop, just exit.

`-o name[=value]`  
`--option=name[=value]`

Pass the option `name` to the output plugin with, if specified, the option value `value`. Which options exist and their effects depends on the used output plugin.

`-P plugin`  
`--plugin=plugin`

When creating a slot, use the specified logical decoding output plugin. See [Chapter 46](#). This option has no effect if the slot already exists.

`-s interval_seconds`  
`--status-interval=interval_seconds`

This option has the same effect as the option of the same name in [pg\\_receivewal](#). See the description there.

`-S slot_name`  
`--slot=slot_name`

In `--start` mode, use the existing logical replication slot named `slot_name`. In `--create-slot` mode, create the slot with this name. In `--drop-slot` mode, delete the slot with this name.

`-v`  
`--verbose`

Enables verbose mode.

The following command-line options control the database connection parameters.

`-d dbname`  
`--dbname=dbname`

The database to connect to. See the description of the actions for what this means in detail. The `dbname` can be a [connection string](#). If so, connection string parameters will override any conflicting command line options. Defaults to the user name.

`-h hostname-or-ip`  
`--host=hostname-or-ip`

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket. The default is taken from the `PGHOST` environment variable, if set, else a Unix domain socket connection is attempted.

`-p port`  
`--port=port`

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections. Defaults to the `PGPORT` environment variable, if set, or a compiled-in default.

`-U user`  
`--username=user`

User name to connect as. Defaults to current operating system user name.

`-w`  
`--no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`  
`--password`

Force `pg_recvlogical` to prompt for a password before connecting to a database.

This option is never essential, since `pg_recvlogical` will automatically prompt for a password if the server demands password authentication. However, `pg_recvlogical` will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-w` to avoid the extra connection attempt.

The following additional options are available:

`-V`  
`--version`

Print the `pg_recvlogical` version and exit.

`-?`  
`--help`

Show help about `pg_recvlogical` command line arguments, and exit.

## Environment

This utility, like most other Postgres Pro utilities, uses the environment variables supported by `libpq` (see [Section 31.14](#)).

The environment variable `PG_COLOR` specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

## Notes

`pg_recvlogical` will preserve group permissions on the received WAL files if group permissions are enabled on the source cluster.

## Examples

See [Section 46.1](#) for an example.

## pg\_restore

`pg_restore` — restore a Postgres Pro database from an archive file created by `pg_dump`

### Synopsis

```
pg_restore [connection-option...] [option...] [filename]
```

### Description

`pg_restore` is a utility for restoring a Postgres Pro database from an archive created by `pg_dump` in one of the non-plain-text formats. It will issue the commands necessary to reconstruct the database to the state it was in at the time it was saved. The archive files also allow `pg_restore` to be selective about what is restored, or even to reorder the items prior to being restored. The archive files are designed to be portable across architectures.

`pg_restore` can operate in two modes. If a database name is specified, `pg_restore` connects to that database and restores archive contents directly into the database. Otherwise, a script containing the SQL commands necessary to rebuild the database is created and written to a file or standard output. This script output is equivalent to the plain text output format of `pg_dump`. Some of the options controlling the output are therefore analogous to `pg_dump` options.

Obviously, `pg_restore` cannot restore information that is not present in the archive file. For instance, if the archive was made using the “dump data as `INSERT` commands” option, `pg_restore` will not be able to load the data using `COPY` statements.

### Options

`pg_restore` accepts the following command line arguments.

*filename*

Specifies the location of the archive file (or directory, for a directory-format archive) to be restored. If not specified, the standard input is used.

`-a`

`--data-only`

Restore only the data, not the schema (data definitions). Table data, large objects, and sequence values are restored, if present in the archive.

This option is similar to, but for historical reasons not identical to, specifying `--section=data`.

`-c`

`--clean`

Clean (drop) database objects before recreating them. (Unless `--if-exists` is used, this might generate some harmless error messages, if any objects were not present in the destination database.)

`-C`

`--create`

Create the database before restoring into it. If `--clean` is also specified, drop and recreate the target database before connecting to it.

With `--create`, `pg_restore` also restores the database's comment if any, and any configuration variable settings that are specific to this database, that is, any `ALTER DATABASE ... SET ...` and `ALTER ROLE ... IN DATABASE ... SET ...` commands that mention this database. Access privileges for the database itself are also restored, unless `--no-acl` is specified.

When this option is used, the database named with `-d` is used only to issue the initial `DROP DATABASE` and `CREATE DATABASE` commands. All data is restored into the database name that appears in the archive.

`-d dbname`  
`--dbname=dbname`

Connect to database `dbname` and restore directly into the database. The `dbname` can be a [connection string](#). If so, connection string parameters will override any conflicting command line options.

`-e`  
`--exit-on-error`

Exit if an error is encountered while sending SQL commands to the database. The default is to continue and to display a count of errors at the end of the restoration.

`-f filename`  
`--file=filename`

Specify output file for generated script, or for the listing when used with `-l`. Use `-` for stdout.

`-F format`  
`--format=format`

Specify format of the archive. It is not necessary to specify the format, since `pg_restore` will determine the format automatically. If specified, it can be one of the following:

`c`  
custom

The archive is in the custom format of `pg_dump`.

`d`  
directory

The archive is a directory archive.

`t`  
tar

The archive is a `tar` archive.

`-I index`  
`--index=index`

Restore definition of named index only. Multiple indexes may be specified with multiple `-I` switches.

`-j number-of-jobs`  
`--jobs=number-of-jobs`

Run the most time-consuming steps of `pg_restore` — those that load data, create indexes, or create constraints — concurrently, using up to `number-of-jobs` concurrent sessions. This option can dramatically reduce the time to restore a large database to a server running on a multiprocessor machine. This option is ignored when emitting a script rather than connecting directly to a database server.

Each job is one process or one thread, depending on the operating system, and uses a separate connection to the server.

The optimal value for this option depends on the hardware setup of the server, of the client, and of the network. Factors include the number of CPU cores and the disk setup. A good place to start is the number of CPU cores on the server, but values larger than that can also lead to faster restore times in many cases. Of course, values that are too high will lead to decreased performance because of thrashing.

---

Only the custom and directory archive formats are supported with this option. The input must be a regular file or directory (not, for example, a pipe or standard input). Also, multiple jobs cannot be used together with the option `--single-transaction`.

`-l`  
`--list`

List the table of contents of the archive. The output of this operation can be used as input to the `-L` option. Note that if filtering switches such as `-n` or `-t` are used with `-l`, they will restrict the items listed.

`-L list-file`  
`--use-list=list-file`

Restore only those archive elements that are listed in *list-file*, and restore them in the order they appear in the file. Note that if filtering switches such as `-n` or `-t` are used with `-L`, they will further restrict the items restored.

*list-file* is normally created by editing the output of a previous `-l` operation. Lines can be moved or removed, and can also be commented out by placing a semicolon (;) at the start of the line. See below for examples.

`-n schema`  
`--schema=schema`

Restore only objects that are in the named schema. Multiple schemas may be specified with multiple `-n` switches. This can be combined with the `-t` option to restore just a specific table.

`-N schema`  
`--exclude-schema=schema`

Do not restore objects that are in the named schema. Multiple schemas to be excluded may be specified with multiple `-N` switches.

When both `-n` and `-N` are given for the same schema name, the `-N` switch wins and the schema is excluded.

`-O`  
`--no-owner`

Do not output commands to set ownership of objects to match the original database. By default, `pg_restore` issues `ALTER OWNER` or `SET SESSION AUTHORIZATION` statements to set ownership of created schema elements. These statements will fail unless the initial connection to the database is made by a superuser (or the same user that owns all of the objects in the script). With `-O`, any user name can be used for the initial connection, and this user will own all the created objects.

`-P function-name (argtype [, ...])`  
`--function=function-name (argtype [, ...])`

Restore the named function only. Be careful to spell the function name and arguments exactly as they appear in the dump file's table of contents. Multiple functions may be specified with multiple `-P` switches.

`-R`  
`--no-reconnect`

This option is obsolete but still accepted for backwards compatibility.

`-s`  
`--schema-only`

Restore only the schema (data definitions), not data, to the extent that schema entries are present in the archive.

This option is the inverse of `--data-only`. It is similar to, but for historical reasons not identical to, specifying `--section=pre-data --section=post-data`.

(Do not confuse this with the `--schema` option, which uses the word “schema” in a different meaning.)

`-S username`  
`--superuser=username`

Specify the superuser user name to use when disabling triggers. This is relevant only if `--disable-triggers` is used.

`-t table`  
`--table=table`

Restore definition and/or data of only the named table. For this purpose, “table” includes views, materialized views, sequences, and foreign tables. Multiple tables can be selected by writing multiple `-t` switches. This option can be combined with the `-n` option to specify table(s) in a particular schema.

### Note

When `-t` is specified, `pg_restore` makes no attempt to restore any other database objects that the selected table(s) might depend upon. Therefore, there is no guarantee that a specific-table restore into a clean database will succeed.

### Note

This flag does not behave identically to the `-t` flag of `pg_dump`. There is not currently any provision for wild-card matching in `pg_restore`, nor can you include a schema name within its `-t`. And, while `pg_dump`'s `-t` flag will also dump subsidiary objects (such as indexes) of the selected table(s), `pg_restore`'s `-t` flag does not include such subsidiary objects.

### Note

In versions prior to Postgres Pro 9.6, this flag matched only tables, not any other type of relation.

`-T trigger`  
`--trigger=trigger`

Restore named trigger only. Multiple triggers may be specified with multiple `-T` switches.

`-v`  
`--verbose`

Specifies verbose mode.

`-V`  
`--version`

Print the `pg_restore` version and exit.

`-x`  
`--no-privileges`  
`--no-acl`

Prevent restoration of access privileges (grant/revoke commands).

- 
- 1
- `--single-transaction`
- Execute the restore as a single transaction (that is, wrap the emitted commands in `BEGIN/COMMIT`). This ensures that either all the commands complete successfully, or no changes are applied. This option implies `--exit-on-error`.
- `--disable-triggers`
- This option is relevant only when performing a data-only restore. It instructs `pg_restore` to execute commands to temporarily disable triggers on the target tables while the data is reloaded. Use this if you have referential integrity checks or other triggers on the tables that you do not want to invoke during data reload.
- Presently, the commands emitted for `--disable-triggers` must be done as superuser. So you should also specify a superuser name with `-s` or, preferably, run `pg_restore` as a Postgres Pro superuser.
- `--enable-row-security`
- This option is relevant only when restoring the contents of a table which has row security. By default, `pg_restore` will set `row_security` to off, to ensure that all data is restored in to the table. If the user does not have sufficient privileges to bypass row security, then an error is thrown. This parameter instructs `pg_restore` to set `row_security` to on instead, allowing the user to attempt to restore the contents of the table with row security enabled. This might still fail if the user does not have the right to insert the rows from the dump into the table.
- Note that this option currently also requires the dump be in `INSERT` format, as `COPY FROM` does not support row security.
- `--if-exists`
- Use conditional commands (i.e., add an `IF EXISTS` clause) to drop database objects. This option is not valid unless `--clean` is also specified.
- `--no-comments`
- Do not output commands to restore comments, even if the archive contains them.
- `--no-data-for-failed-tables`
- By default, table data is restored even if the creation command for the table failed (e.g., because it already exists). With this option, data for such a table is skipped. This behavior is useful if the target database already contains the desired table contents. For example, auxiliary tables for Postgres Pro extensions such as PostGIS might already be loaded in the target database; specifying this option prevents duplicate or obsolete data from being loaded into them.
- This option is effective only when restoring directly into a database, not when producing SQL script output.
- `--no-publications`
- Do not output commands to restore publications, even if the archive contains them.
- `--no-security-labels`
- Do not output commands to restore security labels, even if the archive contains them.
- `--no-subscriptions`
- Do not output commands to restore subscriptions, even if the archive contains them.
- `--no-tablespaces`
- Do not output commands to select tablespaces. With this option, all objects will be created in whichever tablespace is the default during restore.
-

---

`--section=sectionname`

Only restore the named section. The section name can be `pre-data`, `data`, or `post-data`. This option can be specified more than once to select multiple sections. The default is to restore all sections.

The data section contains actual table data as well as large-object definitions. Post-data items consist of definitions of indexes, triggers, rules and constraints other than validated check constraints. Pre-data items consist of all other data definition items.

`--strict-names`

Require that each schema (`-n/--schema`) and table (`-t/--table`) qualifier match at least one schema/table in the backup file.

`--use-set-session-authorization`

Output SQL-standard `SET SESSION AUTHORIZATION` commands instead of `ALTER OWNER` commands to determine object ownership. This makes the dump more standards-compatible, but depending on the history of the objects in the dump, might not restore properly.

`-?`

`--help`

Show help about `pg_restore` command line arguments, and exit.

`pg_restore` also accepts the following command line arguments for connection parameters:

`-h host`

`--host=host`

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket. The default is taken from the `PGHOST` environment variable, if set, else a Unix domain socket connection is attempted.

`-p port`

`--port=port`

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections. Defaults to the `PGPORT` environment variable, if set, or a compiled-in default.

`-U username`

`--username=username`

User name to connect as.

`-w`

`--no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`

`--password`

Force `pg_restore` to prompt for a password before connecting to a database.

This option is never essential, since `pg_restore` will automatically prompt for a password if the server demands password authentication. However, `pg_restore` will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-w` to avoid the extra connection attempt.

`--role=rolename`

Specifies a role name to be used to perform the restore. This option causes `pg_restore` to issue a `SET ROLE rolename` command after connecting to the database. It is useful when the authenticated user

(specified by `-U`) lacks privileges needed by `pg_restore`, but can switch to a role with the required rights. Some installations have a policy against logging in directly as a superuser, and use of this option allows restores to be performed without violating the policy.

## Environment

PGHOST  
PGOPTIONS  
PGPORT  
PGUSER

Default connection parameters

PG\_COLOR

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by `libpq` (see [Section 31.14](#)). However, it does not read `PGDATABASE` when a database name is not supplied.

## Diagnostics

When a direct database connection is specified using the `-d` option, `pg_restore` internally executes SQL statements. If you have problems running `pg_restore`, make sure you are able to select information from the database using, for example, [psql](#). Also, any default connection settings and environment variables used by the `libpq` front-end library will apply.

## Notes

If your installation has any local additions to the `template1` database, be careful to load the output of `pg_restore` into a truly empty database; otherwise you are likely to get errors due to duplicate definitions of the added objects. To make an empty database without any local additions, copy from `template0` not `template1`, for example:

```
CREATE DATABASE foo WITH TEMPLATE template0;
```

The limitations of `pg_restore` are detailed below.

- When restoring data to a pre-existing table and the option `--disable-triggers` is used, `pg_restore` emits commands to disable triggers on user tables before inserting the data, then emits commands to re-enable them after the data has been inserted. If the restore is stopped in the middle, the system catalogs might be left in the wrong state.
- `pg_restore` cannot restore large objects selectively; for instance, only those for a specific table. If an archive contains large objects, then all large objects will be restored, or none of them if they are excluded via `-L`, `-t`, or other options.

See also the [pg\\_dump](#) documentation for details on limitations of `pg_dump`.

Once restored, it is wise to run `ANALYZE` on each restored table so the optimizer has useful statistics; see [Section 23.1.3](#) and [Section 23.1.6](#) for more information.

## Examples

Assume we have dumped a database called `mydb` into a custom-format dump file:

```
$ pg_dump -Fc mydb > db.dump
```

To drop the database and recreate it from the dump:

```
$ dropdb mydb  
$ pg_restore -C -d postgres db.dump
```

The database named in the `-d` switch can be any database existing in the cluster; `pg_restore` only uses it to issue the `CREATE DATABASE` command for `mydb`. With `-C`, data is always restored into the database name that appears in the dump file.

To reload the dump into a new database called `newdb`:

```
$ createdb -T template0 newdb
$ pg_restore -d newdb db.dump
```

Notice we don't use `-C`, and instead connect directly to the database to be restored into. Also note that we clone the new database from `template0` not `template1`, to ensure it is initially empty.

To reorder database items, it is first necessary to dump the table of contents of the archive:

```
$ pg_restore -l db.dump > db.list
```

The listing file consists of a header and one line for each item, e.g.:

```
;
; Archive created at Mon Sep 14 13:55:39 2009
;   dbname: DBDEMOS
;   TOC Entries: 81
;   Compression: 9
;   Dump Version: 1.10-0
;   Format: CUSTOM
;   Integer: 4 bytes
;   Offset: 8 bytes
;   Dumped from database version: 8.3.5
;   Dumped by pg_dump version: 8.3.8
;
;
; Selected TOC Entries:
;
3; 2615 2200 SCHEMA - public pasha
1861; 0 0 COMMENT - SCHEMA public pasha
1862; 0 0 ACL - public pasha
317; 1247 17715 TYPE public composite pasha
319; 1247 25899 DOMAIN public domain0 pasha
```

Semicolons start a comment, and the numbers at the start of lines refer to the internal archive ID assigned to each item.

Lines in the file can be commented out, deleted, and reordered. For example:

```
10; 145433 TABLE map_resolutions postgres
;2; 145344 TABLE species postgres
;4; 145359 TABLE nt_header postgres
6; 145402 TABLE species_records postgres
;8; 145416 TABLE ss_old postgres
```

could be used as input to `pg_restore` and would only restore items 10 and 6, in that order:

```
$ pg_restore -L db.list db.dump
```

# pg-wrapper

pg-wrapper — manage Postgres Pro symbolic links

## Synopsis

```
pg-wrapper links { update | remove }
```

## Description

pg-wrapper is a shell script provided in the Postgres Pro distribution to manage Postgres Pro symbolic links for the provided programs and adjust the handling of SQL man pages on Linux systems. Since Postgres Pro is installed into `/opt/pgpro/std-13`, this is required to make client and server programs available in the standard system `PATH` and find the new SQL man pages. This setup is not performed automatically at installation time to avoid possible conflicts with other PostgreSQL-based products you may have installed, unless you have opted for using the `postgrespro-std-13` quick-install package.

pg-wrapper is provided as part of the `postgrespro-std-13-client` package. Once this package is installed, you can find pg-wrapper in the `install-dir/bin` directory, where `install-dir` is `/opt/pgpro/std-13`.

pg-wrapper must be run as root.

## Options

pg-wrapper accepts the following command-line arguments:

```
links {update | remove}
```

Manage Postgres Pro symbolic links and SQL man pages:

- `update` — create or replace symbolic links for server and client programs provided with Postgres Pro, as well as add SQL man pages to the man page configuration file.
- `remove` — remove symbolic links and SQL man page support for the current Postgres Pro version.

## Notes

If you are installing Postgres Pro from the `postgrespro-std-13` package, pg-wrapper is invoked automatically.

If you are installing individual Postgres Pro packages, you can run this script manually to create symbolic links to the provided client and server programs, as well as add SQL man pages to the man page configuration file.

For parallel installations with other PostgreSQL-based products, pg-wrapper behavior depends on whether the `update-alternatives` utility is supported by your system and the already installed PostgreSQL-based product:

- If `update-alternatives` is supported, pg-wrapper adds symbolic links to Postgres Pro programs into the alternative system, in accordance with their priority, as well as adds SQL man pages to the man page configuration file. For details on how to change the alternatives system priorities, see the man page for `update-alternatives` on your system.

If SQL man pages are already installed from a different product, the pages unique for the new installation will be displayed, while the previous installation will keep its priority for all the coinciding man pages. For the new SQL documentation to be displayed for all pages, you have to modify the system configuration, for example, change the `MANPATH` value.

- If `update-alternatives` is not supported, pg-wrapper updates the system configuration only if there are no conflicts with any programs or man pages already installed. Otherwise, pg-wrapper does

not create or update any program links and skips SQL man page integration. In this case, you can either continue using the already available program versions and SQL man pages, or modify the `PATH` and `MANPATH` settings manually.

For details on binary installation specifics on Linux, see [Section 16.1](#).

# pg\_verifybackup

pg\_verifybackup — verify the integrity of a base backup of a PostgreSQL cluster

## Synopsis

```
pg_verifybackup [option...]
```

## Description

pg\_verifybackup is used to check the integrity of a database cluster backup taken using pg\_basebackup against a backup\_manifest generated by the server at the time of the backup. The backup must be stored in the "plain" format; a "tar" format backup can be checked after extracting it.

It is important to note that the validation which is performed by pg\_verifybackup does not and cannot include every check which will be performed by a running server when attempting to make use of the backup. Even if you use this tool, you should still perform test restores and verify that the resulting databases work as expected and that they appear to contain the correct data. However, pg\_verifybackup can detect many problems that commonly occur due to storage problems or user error.

Backup verification proceeds in four stages. First, pg\_verifybackup reads the backup\_manifest file. If that file does not exist, cannot be read, is malformed, or fails verification against its own internal checksum, pg\_verifybackup will terminate with a fatal error.

Second, pg\_verifybackup will attempt to verify that the data files currently stored on disk are exactly the same as the data files which the server intended to send, with some exceptions that are described below. Extra and missing files will be detected, with a few exceptions. This step will ignore the presence or absence of, or any modifications to, postgresql.auto.conf, standby.signal, and recovery.signal, because it is expected that these files may have been created or modified as part of the process of taking the backup. It also won't complain about a backup\_manifest file in the target directory or about anything inside pg\_wal, even though these files won't be listed in the backup manifest. Only files are checked; the presence or absence of directories is not verified, except indirectly: if a directory is missing, any files it should have contained will necessarily also be missing.

Next, pg\_verifybackup will checksum all the files, compare the checksums against the values in the manifest, and emit errors for any files for which the computed checksum does not match the checksum stored in the manifest. This step is not performed for any files which produced errors in the previous step, since they are already known to have problems. Files which were ignored in the previous step are also ignored in this step.

Finally, pg\_verifybackup will use the manifest to verify that the write-ahead log records which will be needed to recover the backup are present and that they can be read and parsed. The backup\_manifest contains information about which write-ahead log records will be needed, and pg\_verifybackup will use that information to invoke pg\_waldump to parse those write-ahead log records. The --quiet flag will be used, so that pg\_waldump will only report errors, without producing any other output. While this level of verification is sufficient to detect obvious problems such as a missing file or one whose internal checksums do not match, they aren't extensive enough to detect every possible problem that might occur when attempting to recover. For instance, a server bug that produces write-ahead log records that have the correct checksums but specify nonsensical actions can't be detected by this method.

Note that if extra WAL files which are not required to recover the backup are present, they will not be checked by this tool, although a separate invocation of pg\_waldump could be used for that purpose. Also note that WAL verification is version-specific: you must use the version of pg\_verifybackup, and thus of pg\_waldump, which pertains to the backup being checked. In contrast, the data file integrity checks should work with any version of the server that generates a backup\_manifest file.

## Options

pg\_verifybackup accepts the following command-line arguments:

`-e`  
`--exit-on-error`

Exit as soon as a problem with the backup is detected. If this option is not specified, `pg_verifybackup` will continue checking the backup even after a problem has been detected, and will report all problems detected as errors.

`-i path`  
`--ignore=path`

Ignore the specified file or directory, which should be expressed as a relative path name, when comparing the list of data files actually present in the backup to those listed in the `backup_manifest` file. If a directory is specified, this option affects the entire subtree rooted at that location. Complaints about extra files, missing files, file size differences, or checksum mismatches will be suppressed if the relative path name matches the specified path name. This option can be specified multiple times.

`-m path`  
`--manifest-path=path`

Use the manifest file at the specified path, rather than one located in the root of the backup directory.

`-n`  
`--no-parse-wal`

Don't attempt to parse write-ahead log data that will be needed to recover from this backup.

`-q`  
`--quiet`

Don't print anything when a backup is successfully verified.

`-s`  
`--skip-checksums`

Do not verify data file checksums. The presence or absence of files and the sizes of those files will still be checked. This is much faster, because the files themselves do not need to be read.

`-w path`  
`--wal-directory=path`

Try to parse WAL files stored in the specified directory, rather than in `pg_wal`. This may be useful if the backup is stored in a separate location from the WAL archive.

Other options are also available:

`-V`  
`--version`

Print the `pg_verifybackup` version and exit.

`-?`  
`--help`

Show help about `pg_verifybackup` command line arguments, and exit.

## Examples

To create a base backup of the server at `mydbserver` and verify the integrity of the backup:

```
$ pg_basebackup -h mydbserver -D /usr/local/pgsql/data
$ pg_verifybackup /usr/local/pgsql/data
```

To create a base backup of the server at `mydbserver`, move the manifest somewhere outside the backup directory, and verify the backup:

```
$ pg_basebackup -h mydbserver -D /usr/local/pgsql/backup1234
$ mv /usr/local/pgsql/backup1234/backup_manifest /my/secure/location/
backup_manifest.1234
$ pg_verifybackup -m /my/secure/location/backup_manifest.1234 /usr/local/pgsql/
backup1234
```

To verify a backup while ignoring a file that was added manually to the backup directory, and also skipping checksum verification:

```
$ pg_basebackup -h mydbserver -D /usr/local/pgsql/data
$ edit /usr/local/pgsql/data/note.to.self
$ pg_verifybackup --ignore=note.to.self --skip-checksums /usr/local/pgsql/data
```

# psql

psql — Postgres Pro interactive terminal

## Synopsis

```
psql [option...] [dbname [username]]
```

## Description

psql is a terminal-based front-end to Postgres Pro. It enables you to type in queries interactively, issue them to Postgres Pro, and see the query results. Alternatively, input can be from a file or from command line arguments. In addition, psql provides a number of meta-commands and various shell-like features to facilitate writing scripts and automating a wide variety of tasks.

## Options

`-a`  
`--echo-all`  
Print all nonempty input lines to standard output as they are read. (This does not apply to lines read interactively.) This is equivalent to setting the variable `ECHO` to `all`.

`-A`  
`--no-align`  
Switches to unaligned output mode. (The default output mode is aligned.) This is equivalent to `\pset format unaligned`.

`-b`  
`--echo-errors`  
Print failed SQL commands to standard error output. This is equivalent to setting the variable `ECHO` to `errors`.

`-c command`  
`--command=command`  
Specifies that psql is to execute the given command string, *command*. This option can be repeated and combined in any order with the `-f` option. When either `-c` or `-f` is specified, psql does not read commands from standard input; instead it terminates after processing all the `-c` and `-f` options in sequence.

*command* must be either a command string that is completely parsable by the server (i.e., it contains no psql-specific features), or a single backslash command. Thus you cannot mix SQL and psql meta-commands within a `-c` option. To achieve that, you could use repeated `-c` options or pipe the string into psql, for example:

```
psql -c '\x' -c 'SELECT * FROM foo;'
```

or

```
echo '\x \\ SELECT * FROM foo;' | psql
```

(`\\` is the separator meta-command.)

Each SQL command string passed to `-c` is sent to the server as a single request. Because of this, the server executes it as a single transaction even if the string contains multiple SQL commands, unless there are explicit `BEGIN/COMMIT` commands included in the string to divide it into multiple transactions. (See [Section 50.2.2.1](#) for more details about how the server handles multi-query strings.) Also, psql only prints the result of the last SQL command in the string. This is different from

the behavior when the same string is read from a file or fed to psql's standard input, because then psql sends each SQL command separately.

Because of this behavior, putting more than one SQL command in a single `-c` string often has unexpected results. It's better to use repeated `-c` commands or feed multiple commands to psql's standard input, either using echo as illustrated above, or via a shell here-document, for example:

```
psql <<EOF
\x
SELECT * FROM foo;
EOF
```

`--csv`

Switches to CSV (Comma-Separated Values) output mode. This is equivalent to `\pset format csv`.

`-d dbname`

`--dbname=dbname`

Specifies the name of the database to connect to. This is equivalent to specifying `dbname` as the first non-option argument on the command line. The `dbname` can be a [connection string](#). If so, connection string parameters will override any conflicting command line options.

`-e`

`--echo-queries`

Copy all SQL commands sent to the server to standard output as well. This is equivalent to setting the variable `ECHO` to `queries`.

`-E`

`--echo-hidden`

Echo the actual queries generated by `\d` and other backslash commands. You can use this to study psql's internal operations. This is equivalent to setting the variable `ECHO_HIDDEN` to `on`.

`-f filename`

`--file=filename`

Read commands from the file `filename`, rather than standard input. This option can be repeated and combined in any order with the `-c` option. When either `-c` or `-f` is specified, psql does not read commands from standard input; instead it terminates after processing all the `-c` and `-f` options in sequence. Except for that, this option is largely equivalent to the meta-command `\i`.

If `filename` is `-` (hyphen), then standard input is read until an EOF indication or `\q` meta-command. This can be used to intersperse interactive input with input from files. Note however that Readline is not used in this case (much as if `-n` had been specified).

Using this option is subtly different from writing `psql < filename`. In general, both will do what you expect, but using `-f` enables some nice features such as error messages with line numbers. There is also a slight chance that using this option will reduce the start-up overhead. On the other hand, the variant using the shell's input redirection is (in theory) guaranteed to yield exactly the same output you would have received had you entered everything by hand.

`-F separator`

`--field-separator=separator`

Use `separator` as the field separator for unaligned output. This is equivalent to `\pset fieldsep or \f`.

`-h hostname`

`--host=hostname`

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix-domain socket.

-H  
--html

Switches to HTML output mode. This is equivalent to `\pset format html` or the `\H` command.

-l  
--list

List all available databases, then exit. Other non-connection options are ignored. This is similar to the meta-command `\list`.

When this option is used, `psql` will connect to the database `postgres`, unless a different database is named on the command line (option `-d` or non-option argument, possibly via a service entry, but not via an environment variable).

-L *filename*  
--log-file=*filename*

Write all query output into file *filename*, in addition to the normal output destination.

-n  
--no-readline

Do not use Readline for line editing and do not use the command history. This can be useful to turn off tab expansion when cutting and pasting.

-o *filename*  
--output=*filename*

Put all query output into file *filename*. This is equivalent to the command `\o`.

-p *port*  
--port=*port*

Specifies the TCP port or the local Unix-domain socket file extension on which the server is listening for connections. Defaults to the value of the `PGPORT` environment variable or, if not set, to the port specified at compile time, usually 5432.

-P *assignment*  
--pset=*assignment*

Specifies printing options, in the style of `\pset`. Note that here you have to separate name and value with an equal sign instead of a space. For example, to set the output format to LaTeX, you could write `-P format=latex`.

-q  
--quiet

Specifies that `psql` should do its work quietly. By default, it prints welcome messages and various informational output. If this option is used, none of this happens. This is useful with the `-c` option. This is equivalent to setting the variable `QUIET` to `on`.

-R *separator*  
--record-separator=*separator*

Use *separator* as the record separator for unaligned output. This is equivalent to `\pset recordsep`.

-s  
--single-step

Run in single-step mode. That means the user is prompted before each command is sent to the server, with the option to cancel execution as well. Use this to debug scripts.

- `-S`  
`--single-line`  
Runs in single-line mode where a newline terminates an SQL command, as a semicolon does.
- Note**

This mode is provided for those who insist on it, but you are not necessarily encouraged to use it. In particular, if you mix SQL and meta-commands on a line the order of execution might not always be clear to the inexperienced user.
- `-t`  
`--tuples-only`  
Turn off printing of column names and result row count footers, etc. This is equivalent to `\t` or `\pset tuples_only`.
- `-T table_options`  
`--table-attr=table_options`  
Specifies options to be placed within the HTML `table` tag. See `\pset tableattr` for details.
- `-U username`  
`--username=username`  
Connect to the database as the user `username` instead of the default. (You must have permission to do so, of course.)
- `-v assignment`  
`--set=assignment`  
`--variable=assignment`  
Perform a variable assignment, like the `\set` meta-command. Note that you must separate name and value, if any, by an equal sign on the command line. To unset a variable, leave off the equal sign. To set a variable with an empty value, use the equal sign but leave off the value. These assignments are done during command line processing, so variables that reflect connection state will get overwritten later.
- `-V`  
`--version`  
Print the psql version and exit.
- `-w`  
`--no-password`  
Never issue a password prompt. If the server requires password authentication and a password is not available from other sources such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.
- Note that this option will remain set for the entire session, and so it affects uses of the meta-command `\connect` as well as the initial connection attempt.
- `-W`  
`--password`  
Force psql to prompt for a password before connecting to a database, even if the password will not be used.
- If the server requires password authentication and a password is not available from other sources such as a `.pgpass` file, psql will prompt for a password in any case. However, psql will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

Note that this option will remain set for the entire session, and so it affects uses of the meta-command `\connect` as well as the initial connection attempt.

- `-x`  
`--expanded`  
Turn on the expanded table formatting mode. This is equivalent to `\x` or `\pset expanded`.
- `-X,`  
`--no-psqlrc`  
Do not read the start-up file (neither the system-wide `psqlrc` file nor the user's `~/.psqlrc` file).
- `-z`  
`--field-separator-zero`  
Set the field separator for unaligned output to a zero byte. This is equivalent to `\pset fieldsep_zero`.
- `-0`  
`--record-separator-zero`  
Set the record separator for unaligned output to a zero byte. This is useful for interfacing, for example, with `xargs -0`. This is equivalent to `\pset recordsep_zero`.
- `-1`  
`--single-transaction`  
This option can only be used in combination with one or more `-c` and/or `-f` options. It causes `psql` to issue a `BEGIN` command before the first such option and a `COMMIT` command after the last one, thereby wrapping all the commands into a single transaction. This ensures that either all the commands complete successfully, or no changes are applied.  
  
If the commands themselves contain `BEGIN`, `COMMIT`, or `ROLLBACK`, this option will not have the desired effects. Also, if an individual command cannot be executed inside a transaction block, specifying this option will cause the whole transaction to fail.
- `-?`  
`--help[=topic]`  
Show help about `psql` and exit. The optional *topic* parameter (defaulting to `options`) selects which part of `psql` is explained: `commands` describes `psql`'s backslash commands; `options` describes the command-line options that can be passed to `psql`; and `variables` shows help about `psql` configuration variables.

## Exit Status

`psql` returns 0 to the shell if it finished normally, 1 if a fatal error of its own occurs (e.g., out of memory, file not found), 2 if the connection to the server went bad and the session was not interactive, and 3 if an error occurred in a script and the variable `ON_ERROR_STOP` was set.

## Usage

### Connecting to a Database

`psql` is a regular Postgres Pro client application. In order to connect to a database you need to know the name of your target database, the host name and port number of the server, and what user name you want to connect as. `psql` can be told about those parameters via command line options, namely `-d`, `-h`, `-p`, and `-U` respectively. If an argument is found that does not belong to any option it will be interpreted as the database name (or the user name, if the database name is already given). Not all of these options are required; there are useful defaults. If you omit the host name, `psql` will connect via a Unix-domain socket to a server on the local host, or via TCP/IP to `localhost` on machines that don't have Unix-domain sockets. The default port number is determined at compile time. Since the database server uses the same default, you will not have to specify the port in most cases. The default user name is your operating-

system user name, as is the default database name. Note that you cannot just connect to any database under any user name. Your database administrator should have informed you about your access rights.

When the defaults aren't quite right, you can save yourself some typing by setting the environment variables `PGDATABASE`, `PGHOST`, `PGPORT` and/or `PGUSER` to appropriate values. (For additional environment variables, see [Section 31.14](#).) It is also convenient to have a `~/.pgpass` file to avoid regularly having to type in passwords. See [Section 31.15](#) for more information.

An alternative way to specify connection parameters is in a *conninfo* string or a URI, which is used instead of a database name. This mechanism give you very wide control over the connection. For example:

```
$ psql "service=myservice sslmode=require"
$ psql postgresql://dbmaster:5433/mydb?sslmode=require
```

This way you can also use LDAP for connection parameter lookup as described in [Section 31.17](#). See [Section 31.1.2](#) for more information on all the available connection options.

If the connection could not be made for any reason (e.g., insufficient privileges, server is not running on the targeted host, etc.), psql will return an error and terminate.

If both standard input and standard output are a terminal, then psql sets the client encoding to “auto”, which will detect the appropriate client encoding from the locale settings (`LC_CTYPE` environment variable on Unix systems). If this doesn't work out as expected, the client encoding can be overridden using the environment variable `PGCLIENTENCODING`.

## Entering SQL Commands

In normal operation, psql provides a prompt with the name of the database to which psql is currently connected, followed by the string `=>`. For example:

```
$ psql testdb
psql (13.7.2)
Type "help" for help.

testdb=>
```

At the prompt, the user can type in SQL commands. Ordinarily, input lines are sent to the server when a command-terminating semicolon is reached. An end of line does not terminate a command. Thus commands can be spread over several lines for clarity. If the command was sent and executed without error, the results of the command are displayed on the screen.

If untrusted users have access to a database that has not adopted a [secure schema usage pattern](#), begin your session by removing publicly-writable schemas from `search_path`. One can add `options=-csearch_path=` to the connection string or issue `SELECT pg_catalog.set_config('search_path', '', false)` before other SQL commands. This consideration is not specific to psql; it applies to every interface for executing arbitrary SQL commands.

Whenever a command is executed, psql also polls for asynchronous notification events generated by [LISTEN](#) and [NOTIFY](#).

While C-style block comments are passed to the server for processing and removal, SQL-standard comments are removed by psql.

## Meta-Commands

Anything you enter in psql that begins with an unquoted backslash is a psql meta-command that is processed by psql itself. These commands make psql more useful for administration or scripting. Meta-commands are often called slash or backslash commands.

The format of a psql command is the backslash, followed immediately by a command verb, then any arguments. The arguments are separated from the command verb and each other by any number of whitespace characters.

To include whitespace in an argument you can quote it with single quotes. To include a single quote in an argument, write two single quotes within single-quoted text. Anything contained in single quotes is furthermore subject to C-like substitutions for `\n` (new line), `\t` (tab), `\b` (backspace), `\r` (carriage return), `\f` (form feed), `\digits` (octal), and `\xdigits` (hexadecimal). A backslash preceding any other character within single-quoted text quotes that single character, whatever it is.

If an unquoted colon (`:`) followed by a psql variable name appears within an argument, it is replaced by the variable's value, as described in [SQL Interpolation](#) below. The forms `:'variable_name'` and `:"variable_name"` described there work as well. The `:{?variable_name}` syntax allows testing whether a variable is defined. It is substituted by `TRUE` or `FALSE`. Escaping the colon with a backslash protects it from substitution.

Within an argument, text that is enclosed in backquotes (```) is taken as a command line that is passed to the shell. The output of the command (with any trailing newline removed) replaces the backquoted text. Within the text enclosed in backquotes, no special quoting or other processing occurs, except that appearances of `:variable_name` where `variable_name` is a psql variable name are replaced by the variable's value. Also, appearances of `:'variable_name'` are replaced by the variable's value suitably quoted to become a single shell command argument. (The latter form is almost always preferable, unless you are very sure of what is in the variable.) Because carriage return and line feed characters cannot be safely quoted on all platforms, the `:'variable_name'` form prints an error message and does not substitute the variable value when such characters appear in the value.

Some commands take an SQL identifier (such as a table name) as argument. These arguments follow the syntax rules of SQL: Unquoted letters are forced to lowercase, while double quotes (`"`) protect letters from case conversion and allow incorporation of whitespace into the identifier. Within double quotes, paired double quotes reduce to a single double quote in the resulting name. For example, `FOO"BAR"BAZ` is interpreted as `fooBARbaz`, and `"A weird" name"` becomes `A weird name`.

Parsing for arguments stops at the end of the line, or when another unquoted backslash is found. An unquoted backslash is taken as the beginning of a new meta-command. The special sequence `\\` (two backslashes) marks the end of arguments and continues parsing SQL commands, if any. That way SQL and psql commands can be freely mixed on a line. But in any case, the arguments of a meta-command cannot continue beyond the end of the line.

Many of the meta-commands act on the *current query buffer*. This is simply a buffer holding whatever SQL command text has been typed but not yet sent to the server for execution. This will include previous input lines as well as any text appearing before the meta-command on the same line.

The following meta-commands are defined:

`\a`

If the current table output format is unaligned, it is switched to aligned. If it is not unaligned, it is set to unaligned. This command is kept for backwards compatibility. See `\pset` for a more general solution.

`\c` or `\connect` [ `-reuse-previous=on/off` ] [ `dbname` [ `username` ] [ `host` ] [ `port` ] | `conninfo` ]

Establishes a new connection to a Postgres Pro server. The connection parameters to use can be specified either using a positional syntax (one or more of database name, user, host, and port), or using a `conninfo` connection string as detailed in [Section 31.1.1](#). If no arguments are given, a new connection is made using the same parameters as before.

Specifying any of `dbname`, `username`, `host` or `port` as `-` is equivalent to omitting that parameter.

The new connection can re-use connection parameters from the previous connection; not only database name, user, host, and port, but other settings such as `sslmode`. By default, parameters are re-used in the positional syntax, but not when a `conninfo` string is given. Passing a first argument of `-reuse-previous=on` or `-reuse-previous=off` overrides that default. If parameters are re-used, then any parameter not explicitly specified as a positional parameter or in the `conninfo` string is taken

from the existing connection's parameters. An exception is that if the *host* setting is changed from its previous value using the positional syntax, any *hostaddr* setting present in the existing connection's parameters is dropped. Also, any password used for the existing connection will be re-used only if the user, host, and port settings are not changed. When the command neither specifies nor reuses a particular parameter, the libpq default is used.

If the new connection is successfully made, the previous connection is closed. If the connection attempt fails (wrong user name, access denied, etc.), the previous connection will be kept if psql is in interactive mode. But when executing a non-interactive script, processing will immediately stop with an error. This distinction was chosen as a user convenience against typos on the one hand, and a safety mechanism that scripts are not accidentally acting on the wrong database on the other hand.

Examples:

```
=> \c mydb myuser host.dom 6432
=> \c service=foo
=> \c "host=localhost port=5432 dbname=mydb connect_timeout=10 sslmode=disable"
=> \c -reuse-previous=on sslmode=require -- changes only sslmode
=> \c postgresql://tom@localhost/mydb?application_name=myapp
```

`\C [ title ]`

Sets the title of any tables being printed as the result of a query or unset any such title. This command is equivalent to `\pset title title`. (The name of this command derives from “caption”, as it was previously only used to set the caption in an HTML table.)

`\cd [ directory ]`

Changes the current working directory to *directory*. Without argument, changes to the current user's home directory.

### Tip

To print your current working directory, use `\! pwd`.

`\conninfo`

Outputs information about the current database connection.

```
\copy { table [ ( column_list ) ] } from { 'filename' | program 'command' | stdin |
pstdin } [ [ with ] ( option [, ...] ) ] [ where condition ]
\copy { table [ ( column_list ) ] | ( query ) } to { 'filename' | program 'command' |
stdout | pstdout } [ [ with ] ( option [, ...] ) ]
```

Performs a frontend (client) copy. This is an operation that runs an SQL `COPY` command, but instead of the server reading or writing the specified file, psql reads or writes the file and routes the data between the server and the local file system. This means that file accessibility and privileges are those of the local user, not the server, and no SQL superuser privileges are required.

When *program* is specified, *command* is executed by psql and the data passed from or to *command* is routed between the server and the client. Again, the execution privileges are those of the local user, not the server, and no SQL superuser privileges are required.

For `\copy ... from stdin`, data rows are read from the same source that issued the command, continuing until `\.` is read or the stream reaches EOF. This option is useful for populating tables in-line within a SQL script file. For `\copy ... to stdout`, output is sent to the same place as psql command output, and the `COPY count` command status is not printed (since it might be confused with a data row). To read/write psql's standard input or output regardless of the current command source or `\o` option, write `from pstdin` or `to pstdout`.

The syntax of this command is similar to that of the SQL `COPY` command. All options other than the data source/destination are as specified for `COPY`. Because of this, special parsing rules apply to the

`\copy` meta-command. Unlike most other meta-commands, the entire remainder of the line is always taken to be the arguments of `\copy`, and neither variable interpolation nor backquote expansion are performed in the arguments.

### Tip

Another way to obtain the same result as `\copy ...` to is to use the SQL `COPY ... TO STDOUT` command and terminate it with `\g filename` or `\g |program`. Unlike `\copy`, this method allows the command to span multiple lines; also, variable interpolation and backquote expansion can be used.

### Tip

These operations are not as efficient as the SQL `COPY` command with a file or program data source or destination, because all data must pass through the client/server connection. For large amounts of data the SQL command might be preferable.

`\copyright`

Shows the copyright and distribution terms of Postgres Pro.

`\crosstabview [ colV [ colH [ colD [ sortcolH ] ] ] ]`

Executes the current query buffer (like `\g`) and shows the results in a crosstab grid. The query must return at least three columns. The output column identified by `colV` becomes a vertical header and the output column identified by `colH` becomes a horizontal header. `colD` identifies the output column to display within the grid. `sortcolH` identifies an optional sort column for the horizontal header.

Each column specification can be a column number (starting at 1) or a column name. The usual SQL case folding and quoting rules apply to column names. If omitted, `colV` is taken as column 1 and `colH` as column 2. `colH` must differ from `colV`. If `colD` is not specified, then there must be exactly three columns in the query result, and the column that is neither `colV` nor `colH` is taken to be `colD`.

The vertical header, displayed as the leftmost column, contains the values found in column `colV`, in the same order as in the query results, but with duplicates removed.

The horizontal header, displayed as the first row, contains the values found in column `colH`, with duplicates removed. By default, these appear in the same order as in the query results. But if the optional `sortcolH` argument is given, it identifies a column whose values must be integer numbers, and the values from `colH` will appear in the horizontal header sorted according to the corresponding `sortcolH` values.

Inside the crosstab grid, for each distinct value  $x$  of `colH` and each distinct value  $y$  of `colV`, the cell located at the intersection  $(x, y)$  contains the value of the `colD` column in the query result row for which the value of `colH` is  $x$  and the value of `colV` is  $y$ . If there is no such row, the cell is empty. If there are multiple such rows, an error is reported.

`\d[S+] [ pattern ]`

For each relation (table, view, materialized view, index, sequence, or foreign table) or composite type matching the `pattern`, show all columns, their types, the tablespace (if not the default) and any special attributes such as `NOT NULL` or defaults. Associated indexes, constraints, rules, and triggers are also shown. For foreign tables, the associated foreign server is shown as well. (“Matching the pattern” is defined in [Patterns](#) below.)

For some types of relation, `\d` shows additional information for each column: column values for sequences, indexed expressions for indexes, and foreign data wrapper options for foreign tables.

The command form `\d+` is identical, except that more information is displayed: any comments associated with the columns of the table are shown, as is the presence of OIDs in the table, the view definition if the relation is a view, a non-default [replica identity](#) setting.

By default, only user-created objects are shown; supply a `pattern` or the `s` modifier to include system objects.

### Note

If `\d` is used without a `pattern` argument, it is equivalent to `\dtvmsE` which will show a list of all visible tables, views, materialized views, sequences and foreign tables. This is purely a convenience measure.

`\da[S] [ pattern ]`

Lists aggregate functions, together with their return type and the data types they operate on. If `pattern` is specified, only aggregates whose names match the pattern are shown. By default, only user-created objects are shown; supply a `pattern` or the `s` modifier to include system objects.

`\dA[+] [ pattern ]`

Lists access methods. If `pattern` is specified, only access methods whose names match the pattern are shown. If `+` is appended to the command name, each access method is listed with its associated handler function and description.

`\dAc[+] [access-method-pattern [input-type-pattern]]`

Lists operator classes (see [Section 35.16.1](#)). If `access-method-pattern` is specified, only operator classes associated with access methods whose names match that pattern are listed. If `input-type-pattern` is specified, only operator classes associated with input types whose names match that pattern are listed. If `+` is appended to the command name, each operator class is listed with its associated operator family and owner.

`\dAf[+] [access-method-pattern [input-type-pattern]]`

Lists operator families (see [Section 35.16.5](#)). If `access-method-pattern` is specified, only operator families associated with access methods whose names match that pattern are listed. If `input-type-pattern` is specified, only operator families associated with input types whose names match that pattern are listed. If `+` is appended to the command name, each operator family is listed with its owner.

`\dAo[+] [access-method-pattern [operator-family-pattern]]`

Lists operators associated with operator families (see [Section 35.16.2](#)). If `access-method-pattern` is specified, only members of operator families associated with access methods whose names match that pattern are listed. If `operator-family-pattern` is specified, only members of operator families whose names match that pattern are listed. If `+` is appended to the command name, each operator is listed with its sort operator family (if it is an ordering operator).

`\dAp[+] [access-method-pattern [operator-family-pattern]]`

Lists support functions associated with operator families (see [Section 35.16.3](#)). If `access-method-pattern` is specified, only functions of operator families associated with access methods whose names match that pattern are listed. If `operator-family-pattern` is specified, only functions of operator families whose names match that pattern are listed. If `+` is appended to the command name, functions are displayed verbosely, with their actual parameter lists.

`\db[+] [ pattern ]`

Lists tablespaces. If `pattern` is specified, only tablespaces whose names match the pattern are shown. If `+` is appended to the command name, each tablespace is listed with its associated options, on-disk size, permissions and description.

`\dc[S+] [ pattern ]`

Lists conversions between character-set encodings. If *pattern* is specified, only conversions whose names match the pattern are listed. By default, only user-created objects are shown; supply a pattern or the *s* modifier to include system objects. If + is appended to the command name, each object is listed with its associated description.

`\dC[+] [ pattern ]`

Lists type casts. If *pattern* is specified, only casts whose source or target types match the pattern are listed. If + is appended to the command name, each object is listed with its associated description.

`\dd[S] [ pattern ]`

Shows the descriptions of objects of type `constraint`, `operator class`, `operator family`, `rule`, and `trigger`. All other comments may be viewed by the respective backslash commands for those object types.

`\dd` displays descriptions for objects matching the *pattern*, or of visible objects of the appropriate type if no argument is given. But in either case, only objects that have a description are listed. By default, only user-created objects are shown; supply a pattern or the *s* modifier to include system objects.

Descriptions for objects can be created with the [COMMENT SQL](#) command.

`\dD[S+] [ pattern ]`

Lists domains. If *pattern* is specified, only domains whose names match the pattern are shown. By default, only user-created objects are shown; supply a pattern or the *s* modifier to include system objects. If + is appended to the command name, each object is listed with its associated permissions and description.

`\ddp [ pattern ]`

Lists default access privilege settings. An entry is shown for each role (and schema, if applicable) for which the default privilege settings have been changed from the built-in defaults. If *pattern* is specified, only entries whose role name or schema name matches the pattern are listed.

The [ALTER DEFAULT PRIVILEGES](#) command is used to set default access privileges. The meaning of the privilege display is explained in [Section 5.7](#).

`\dE[S+] [ pattern ]`

`\di[S+] [ pattern ]`

`\dm[S+] [ pattern ]`

`\ds[S+] [ pattern ]`

`\dt[S+] [ pattern ]`

`\dv[S+] [ pattern ]`

In this group of commands, the letters *E*, *i*, *m*, *s*, *t*, and *v* stand for foreign table, index, materialized view, sequence, table, and view, respectively. You can specify any or all of these letters, in any order, to obtain a listing of objects of these types. For example, `\dti` lists tables and indexes. If + is appended to the command name, each object is listed with its persistence status (permanent, temporary, or unlogged), physical size on disk, and associated description if any. If *pattern* is specified, only objects whose names match the pattern are listed. By default, only user-created objects are shown; supply a pattern or the *s* modifier to include system objects.

`\des[+] [ pattern ]`

Lists foreign servers (mnemonic: “external servers”). If *pattern* is specified, only those servers whose name matches the pattern are listed. If the form `\des+` is used, a full description of each server is shown, including the server's access privileges, type, version, options, and description.

`\det[+] [ pattern ]`

Lists foreign tables (mnemonic: “external tables”). If *pattern* is specified, only entries whose table name or schema name matches the pattern are listed. If the form `\det+` is used, generic options and the foreign table description are also displayed.

`\deu[+] [ pattern ]`

Lists user mappings (mnemonic: “external users”). If *pattern* is specified, only those mappings whose user names match the pattern are listed. If the form `\deu+` is used, additional information about each mapping is shown.

### Caution

`\deu+` might also display the user name and password of the remote user, so care should be taken not to disclose them.

`\dew[+] [ pattern ]`

Lists foreign-data wrappers (mnemonic: “external wrappers”). If *pattern* is specified, only those foreign-data wrappers whose name matches the pattern are listed. If the form `\dew+` is used, the access privileges, options, and description of the foreign-data wrapper are also shown.

`\df[anptwS+] [ pattern ]`

Lists functions, together with their result data types, argument data types, and function types, which are classified as “agg” (aggregate), “normal”, “procedure”, “trigger”, or “window”. To display only functions of specific type(s), add the corresponding letters *a*, *n*, *p*, *t*, or *w* to the command. If *pattern* is specified, only functions whose names match the pattern are shown. By default, only user-created objects are shown; supply a pattern or the *s* modifier to include system objects. If the form `\df+` is used, additional information about each function is shown, including volatility, parallel safety, owner, security classification, access privileges, language, source code and description.

### Tip

To look up functions taking arguments or returning values of a specific data type, use your pager's search capability to scroll through the `\df` output.

`\dF[+] [ pattern ]`

Lists text search configurations. If *pattern* is specified, only configurations whose names match the pattern are shown. If the form `\dF+` is used, a full description of each configuration is shown, including the underlying text search parser and the dictionary list for each parser token type.

`\dFd[+] [ pattern ]`

Lists text search dictionaries. If *pattern* is specified, only dictionaries whose names match the pattern are shown. If the form `\dFd+` is used, additional information is shown about each selected dictionary, including the underlying text search template and the option values.

`\dFp[+] [ pattern ]`

Lists text search parsers. If *pattern* is specified, only parsers whose names match the pattern are shown. If the form `\dFp+` is used, a full description of each parser is shown, including the underlying functions and the list of recognized token types.

`\dFt[+] [ pattern ]`

Lists text search templates. If *pattern* is specified, only templates whose names match the pattern are shown. If the form `\dFt+` is used, additional information is shown about each template, including the underlying function names.

---

`\dg[S+] [ pattern ]`

Lists database roles. (Since the concepts of “users” and “groups” have been unified into “roles”, this command is now equivalent to `\du`.) By default, only user-created roles are shown; supply the *s* modifier to include system roles. If *pattern* is specified, only those roles whose names match the *pattern* are listed. If the form `\dg+` is used, additional information is shown about each role; currently this adds the comment for each role.

`\dl`

This is an alias for `\lo_list`, which shows a list of large objects.

`\dL[S+] [ pattern ]`

Lists procedural languages. If *pattern* is specified, only languages whose names match the *pattern* are listed. By default, only user-created languages are shown; supply the *s* modifier to include system objects. If *+* is appended to the command name, each language is listed with its call handler, validator, access privileges, and whether it is a system object.

`\dn[S+] [ pattern ]`

Lists schemas (namespaces). If *pattern* is specified, only schemas whose names match the *pattern* are listed. By default, only user-created objects are shown; supply a *pattern* or the *s* modifier to include system objects. If *+* is appended to the command name, each object is listed with its associated permissions and description, if any.

`\do[S+] [ pattern ]`

Lists operators with their operand and result types. If *pattern* is specified, only operators whose names match the *pattern* are listed. By default, only user-created objects are shown; supply a *pattern* or the *s* modifier to include system objects. If *+* is appended to the command name, additional information about each operator is shown, currently just the name of the underlying function.

`\dO[S+] [ pattern ]`

Lists collations. If *pattern* is specified, only collations whose names match the *pattern* are listed. By default, only user-created objects are shown; supply a *pattern* or the *s* modifier to include system objects. If *+* is appended to the command name, each collation is listed with its associated description, if any. Note that only collations usable with the current database's encoding are shown, so the results may vary in different databases of the same installation.

`\dp [ pattern ]`

Lists tables, views and sequences with their associated access privileges. If *pattern* is specified, only tables, views and sequences whose names match the *pattern* are listed.

The [GRANT](#) and [REVOKE](#) commands are used to set access privileges. The meaning of the privilege display is explained in [Section 5.7](#).

`\dP[itn+] [ pattern ]`

Lists partitioned relations. If *pattern* is specified, only entries whose name matches the *pattern* are listed. The modifiers *t* (tables) and *i* (indexes) can be appended to the command, filtering the kind of relations to list. By default, partitioned tables and indexes are listed.

If the modifier *n* (“nested”) is used, or a *pattern* is specified, then non-root partitioned relations are included, and a column is shown displaying the parent of each partitioned relation.

If *+* is appended to the command name, the sum of the sizes of each relation's partitions is also displayed, along with the relation's description. If *n* is combined with *+*, two sizes are shown: one including the total size of directly-attached leaf partitions, and another showing the total size of all partitions, including indirectly attached sub-partitions.

---

```
\drds [ role-pattern [ database-pattern ] ]
```

Lists defined configuration settings. These settings can be role-specific, database-specific, or both. *role-pattern* and *database-pattern* are used to select specific roles and databases to list, respectively. If omitted, or if \* is specified, all settings are listed, including those not role-specific or database-specific, respectively.

The [ALTER ROLE](#) and [ALTER DATABASE](#) commands are used to define per-role and per-database configuration settings.

```
\dRp[+] [ pattern ]
```

Lists replication publications. If *pattern* is specified, only those publications whose names match the *pattern* are listed. If + is appended to the command name, the tables associated with each publication are shown as well.

```
\dRs[+] [ pattern ]
```

Lists replication subscriptions. If *pattern* is specified, only those subscriptions whose names match the *pattern* are listed. If + is appended to the command name, additional properties of the subscriptions are shown.

```
\dT[S+] [ pattern ]
```

Lists data types. If *pattern* is specified, only types whose names match the *pattern* are listed. If + is appended to the command name, each type is listed with its internal name and size, its allowed values if it is an `enum` type, and its associated permissions. By default, only user-created objects are shown; supply a *pattern* or the `s` modifier to include system objects.

```
\du[S+] [ pattern ]
```

Lists database roles. (Since the concepts of “users” and “groups” have been unified into “roles”, this command is now equivalent to `\dg`.) By default, only user-created roles are shown; supply the `s` modifier to include system roles. If *pattern* is specified, only those roles whose names match the *pattern* are listed. If the form `\du+` is used, additional information is shown about each role; currently this adds the comment for each role.

```
\dx[+] [ pattern ]
```

Lists installed extensions. If *pattern* is specified, only those extensions whose names match the *pattern* are listed. If the form `\dx+` is used, all the objects belonging to each matching extension are listed.

```
\dy[+] [ pattern ]
```

Lists event triggers. If *pattern* is specified, only those event triggers whose names match the *pattern* are listed. If + is appended to the command name, each object is listed with its associated description.

```
\e or \edit [ filename ] [ line_number ]
```

If *filename* is specified, the file is edited; after the editor exits, the file's content is copied into the current query buffer. If no *filename* is given, the current query buffer is copied to a temporary file which is then edited in the same fashion. Or, if the current query buffer is empty, the most recently executed query is copied to a temporary file and edited in the same fashion.

The new contents of the query buffer are then re-parsed according to the normal rules of psql, treating the whole buffer as a single line. Any complete queries are immediately executed; that is, if the query buffer contains or ends with a semicolon, everything up to that point is executed and removed from the query buffer. Whatever remains in the query buffer is redisplayed. Type semicolon or `\g` to send it, or `\r` to cancel it by clearing the query buffer.

Treating the buffer as a single line primarily affects meta-commands: whatever is in the buffer after a meta-command will be taken as argument(s) to the meta-command, even if it spans multiple lines. (Thus you cannot make meta-command-using scripts this way. Use `\i` for that.)

If a line number is specified, psql will position the cursor on the specified line of the file or query buffer. Note that if a single all-digits argument is given, psql assumes it is a line number, not a file name.

### Tip

See [Environment](#), below, for how to configure and customize your editor.

`\echo text [ ... ]`

Prints the evaluated arguments to standard output, separated by spaces and followed by a newline. This can be useful to intersperse information in the output of scripts. For example:

```
=> \echo `date`
Tue Oct 26 21:40:57 CEST 1999
```

If the first argument is an unquoted `-n` the trailing newline is not written (nor is the first argument).

### Tip

If you use the `\o` command to redirect your query output you might wish to use `\qecho` instead of this command. See also `\warn`.

`\ef [ function_description [ line_number ] ]`

This command fetches and edits the definition of the named function or procedure, in the form of a `CREATE OR REPLACE FUNCTION` or `CREATE OR REPLACE PROCEDURE` command. Editing is done in the same way as for `\edit`. After the editor exits, the updated command is executed immediately if you added a semicolon to it. Otherwise it is redisplayed; type semicolon or `\g` to send it, or `\r` to cancel.

The target function can be specified by name alone, or by name and arguments, for example `foo(integer, text)`. The argument types must be given if there is more than one function of the same name.

If no function is specified, a blank `CREATE FUNCTION` template is presented for editing.

If a line number is specified, psql will position the cursor on the specified line of the function body. (Note that the function body typically does not begin on the first line of the file.)

Unlike most other meta-commands, the entire remainder of the line is always taken to be the argument(s) of `\ef`, and neither variable interpolation nor backquote expansion are performed in the arguments.

### Tip

See [Environment](#), below, for how to configure and customize your editor.

`\encoding [ encoding ]`

Sets the client character set encoding. Without an argument, this command shows the current encoding.

`\errverbose`

Repeats the most recent server error message at maximum verbosity, as though `VERBOSITY` were set to `verbose` and `SHOW_CONTEXT` were set to `always`.

```
\ev [ view_name [ line_number ] ]
```

This command fetches and edits the definition of the named view, in the form of a `CREATE OR REPLACE VIEW` command. Editing is done in the same way as for `\edit`. After the editor exits, the updated command is executed immediately if you added a semicolon to it. Otherwise it is redisplayed; type semicolon or `\g` to send it, or `\r` to cancel.

If no view is specified, a blank `CREATE VIEW` template is presented for editing.

If a line number is specified, `psql` will position the cursor on the specified line of the view definition.

Unlike most other meta-commands, the entire remainder of the line is always taken to be the argument(s) of `\ev`, and neither variable interpolation nor backquote expansion are performed in the arguments.

```
\f [ string ]
```

Sets the field separator for unaligned query output. The default is the vertical bar (`|`). It is equivalent to `\pset fieldsep`.

```
\g [ (option=value [...]) ] [ filename ]
```

```
\g [ (option=value [...]) ] [ |command ]
```

Sends the current query buffer to the server for execution.

If parentheses appear after `\g`, they surround a space-separated list of `option=value` formatting-option clauses, which are interpreted in the same way as `\pset option value` commands, but take effect only for the duration of this query. In this list, spaces are not allowed around `=` signs, but are required between option clauses. If `=value` is omitted, the named `option` is changed in the same way as for `\pset option` with no explicit `value`.

If a `filename` or `|command` argument is given, the query's output is written to the named file or piped to the given shell command, instead of displaying it as usual. The file or command is written to only if the query successfully returns zero or more tuples, not if the query fails or is a non-data-returning SQL command.

If the current query buffer is empty, the most recently sent query is re-executed instead. Except for that behavior, `\g` without any arguments is essentially equivalent to a semicolon. With arguments, `\g` provides a “one-shot” alternative to the `\o` command, and additionally allows one-shot adjustments of the output formatting options normally set by `\pset`.

When the last argument begins with `|`, the entire remainder of the line is taken to be the `command` to execute, and neither variable interpolation nor backquote expansion are performed in it. The rest of the line is simply passed literally to the shell.

```
\gdesc
```

Shows the description (that is, the column names and data types) of the result of the current query buffer. The query is not actually executed; however, if it contains some type of syntax error, that error will be reported in the normal way.

If the current query buffer is empty, the most recently sent query is described instead.

```
\gexec
```

Sends the current query buffer to the server, then treats each column of each row of the query's output (if any) as a SQL statement to be executed. For example, to create an index on each column of `my_table`:

```
=> SELECT format('create index on my_table(%I)', attname)
-> FROM pg_attribute
-> WHERE attrelid = 'my_table'::regclass AND attnum > 0
-> ORDER BY attnum
```

```
-> \gexec
CREATE INDEX
CREATE INDEX
CREATE INDEX
CREATE INDEX
```

The generated queries are executed in the order in which the rows are returned, and left-to-right within each row if there is more than one column. NULL fields are ignored. The generated queries are sent literally to the server for processing, so they cannot be psql meta-commands nor contain psql variable references. If any individual query fails, execution of the remaining queries continues unless `ON_ERROR_STOP` is set. Execution of each query is subject to `ECHO` processing. (Setting `ECHO` to `all` or `queries` is often advisable when using `\gexec`.) Query logging, single-step mode, timing, and other query execution features apply to each generated query as well.

If the current query buffer is empty, the most recently sent query is re-executed instead.

```
\gset [ prefix ]
```

Sends the current query buffer to the server and stores the query's output into psql variables (see [Variables](#) below). The query to be executed must return exactly one row. Each column of the row is stored into a separate variable, named the same as the column. For example:

```
=> SELECT 'hello' AS var1, 10 AS var2
-> \gset
=> \echo :var1 :var2
hello 10
```

If you specify a *prefix*, that string is prepended to the query's column names to create the variable names to use:

```
=> SELECT 'hello' AS var1, 10 AS var2
-> \gset result_
=> \echo :result_var1 :result_var2
hello 10
```

If a column result is NULL, the corresponding variable is unset rather than being set.

If the query fails or does not return one row, no variables are changed.

If the current query buffer is empty, the most recently sent query is re-executed instead.

```
\gx [ (option=value [...]) ] [ filename ]
\x [ (option=value [...]) ] [ |command ]
```

`\gx` is equivalent to `\g`, except that it forces expanded output mode for this query, as if `expanded=on` were included in the list of `\pset` options. See also `\x`.

```
\h or \help [ command ]
```

Gives syntax help on the specified SQL command. If *command* is not specified, then psql will list all the commands for which syntax help is available. If *command* is an asterisk (\*), then syntax help on all SQL commands is shown.

Unlike most other meta-commands, the entire remainder of the line is always taken to be the argument(s) of `\help`, and neither variable interpolation nor backquote expansion are performed in the arguments.

### Note

To simplify typing, commands that consists of several words do not have to be quoted. Thus it is fine to type `\help alter table`.

`\H` or `\html`

Turns on HTML query output format. If the HTML format is already on, it is switched back to the default aligned text format. This command is for compatibility and convenience, but see `\pset` about setting other output options.

`\i` or `\include filename`

Reads input from the file *filename* and executes it as though it had been typed on the keyboard.

If *filename* is `-` (hyphen), then standard input is read until an EOF indication or `\q` meta-command. This can be used to intersperse interactive input with input from files. Note that Readline behavior will be used only if it is active at the outermost level.

### Note

If you want to see the lines on the screen as they are read you must set the variable `ECHO` to `all`.

`\if expression`

`\elif expression`

`\else`

`\endif`

This group of commands implements nestable conditional blocks. A conditional block must begin with an `\if` and end with an `\endif`. In between there may be any number of `\elif` clauses, which may optionally be followed by a single `\else` clause. Ordinary queries and other types of backslash commands may (and usually do) appear between the commands forming a conditional block.

The `\if` and `\elif` commands read their argument(s) and evaluate them as a boolean expression. If the expression yields `true` then processing continues normally; otherwise, lines are skipped until a matching `\elif`, `\else`, or `\endif` is reached. Once an `\if` or `\elif` test has succeeded, the arguments of later `\elif` commands in the same block are not evaluated but are treated as `false`. Lines following an `\else` are processed only if no earlier matching `\if` or `\elif` succeeded.

The *expression* argument of an `\if` or `\elif` command is subject to variable interpolation and backquote expansion, just like any other backslash command argument. After that it is evaluated like the value of an on/off option variable. So a valid value is any unambiguous case-insensitive match for one of: `true`, `false`, `1`, `0`, `on`, `off`, `yes`, `no`. For example, `t`, `T`, and `tR` will all be considered to be `true`.

Expressions that do not properly evaluate to `true` or `false` will generate a warning and be treated as `false`.

Lines being skipped are parsed normally to identify queries and backslash commands, but queries are not sent to the server, and backslash commands other than conditionals (`\if`, `\elif`, `\else`, `\endif`) are ignored. Conditional commands are checked only for valid nesting. Variable references in skipped lines are not expanded, and backquote expansion is not performed either.

All the backslash commands of a given conditional block must appear in the same source file. If EOF is reached on the main input file or an `\include`-ed file before all local `\if`-blocks have been closed, then `psql` will raise an error.

Here is an example:

```
-- check for the existence of two separate records in the database and store
-- the results in separate psql variables
SELECT
    EXISTS(SELECT 1 FROM customer WHERE customer_id = 123) as is_customer,
    EXISTS(SELECT 1 FROM employee WHERE employee_id = 456) as is_employee
\gset
```

```

\if :is_customer
    SELECT * FROM customer WHERE customer_id = 123;
\elif :is_employee
    \echo 'is not a customer but is an employee'
    SELECT * FROM employee WHERE employee_id = 456;
\else
    \if yes
        \echo 'not a customer or employee'
    \else
        \echo 'this will never print'
    \endif
\endif

```

`\ir` or `\include_relative filename`

The `\ir` command is similar to `\i`, but resolves relative file names differently. When executing in interactive mode, the two commands behave identically. However, when invoked from a script, `\ir` interprets file names relative to the directory in which the script is located, rather than the current working directory.

`\l[+]` or `\list[+]` [ *pattern* ]

List the databases in the server and show their names, owners, character set encodings, and access privileges. If *pattern* is specified, only databases whose names match the pattern are listed. If `+` is appended to the command name, database sizes, default tablespaces, and descriptions are also displayed. (Size information is only available for databases that the current user can connect to.)

`\lo_export oid filename`

Reads the large object with OID *oid* from the database and writes it to *filename*. Note that this is subtly different from the server function `lo_export`, which acts with the permissions of the user that the database server runs as and on the server's file system.

### Tip

Use `\lo_list` to find out the large object's OID.

`\lo_import filename [ comment ]`

Stores the file into a Postgres Pro large object. Optionally, it associates the given comment with the object. Example:

```
foo=> \lo_import '/home/peter/pictures/photo.xcf' 'a picture of me'
lo_import 152801
```

The response indicates that the large object received object ID 152801, which can be used to access the newly-created large object in the future. For the sake of readability, it is recommended to always associate a human-readable comment with every object. Both OIDs and comments can be viewed with the `\lo_list` command.

Note that this command is subtly different from the server-side `lo_import` because it acts as the local user on the local file system, rather than the server's user and file system.

`\lo_list`

Shows a list of all Postgres Pro large objects currently stored in the database, along with any comments provided for them.

`\lo_unlink oid`

Deletes the large object with OID *oid* from the database.

**Tip**

Use `\lo_list` to find out the large object's OID.

```
\o or \out [ filename ]
\o or \out [ |command ]
```

Arranges to save future query results to the file *filename* or pipe future results to the shell command *command*. If no argument is specified, the query output is reset to the standard output.

If the argument begins with `|`, then the entire remainder of the line is taken to be the *command* to execute, and neither variable interpolation nor backquote expansion are performed in it. The rest of the line is simply passed literally to the shell.

“Query results” includes all tables, command responses, and notices obtained from the database server, as well as output of various backslash commands that query the database (such as `\d`); but not error messages.

**Tip**

To intersperse text output in between query results, use `\qecho`.

```
\p or \print
```

Print the current query buffer to the standard output. If the current query buffer is empty, the most recently executed query is printed instead.

```
\password [ username ]
```

Changes the password of the specified user (by default, the current user). This command prompts for the new password, encrypts it, and sends it to the server as an `ALTER ROLE` command. This makes sure that the new password does not appear in cleartext in the command history, the server log, or elsewhere.

```
\prompt [ text ] name
```

Prompts the user to supply text, which is assigned to the variable *name*. An optional prompt string, *text*, can be specified. (For multiword prompts, surround the text with single quotes.)

By default, `\prompt` uses the terminal for input and output. However, if the `-f` command line switch was used, `\prompt` uses standard input and standard output.

```
\pset [ option [ value ] ]
```

This command sets options affecting the output of query result tables. *option* indicates which option is to be set. The semantics of *value* vary depending on the selected option. For some options, omitting *value* causes the option to be toggled or unset, as described under the particular option. If no such behavior is mentioned, then omitting *value* just results in the current setting being displayed.

`\pset` without any arguments displays the current status of all printing options.

Adjustable printing options are:

```
border
```

The *value* must be a number. In general, the higher the number the more borders and lines the tables will have, but details depend on the particular format. In HTML format, this will translate directly into the `border=...` attribute. In most other formats only values 0 (no border), 1 (internal dividing lines), and 2 (table frame) make sense, and values above 2 will be treated the same

---

as `border = 2`. The `latex` and `latex-longtable` formats additionally allow a value of 3 to add dividing lines between data rows.

#### `columns`

Sets the target width for the `wrapped` format, and also the width limit for determining whether output is wide enough to require the pager or switch to the vertical display in expanded auto mode. Zero (the default) causes the target width to be controlled by the environment variable `COLUMNS`, or the detected screen width if `COLUMNS` is not set. In addition, if `columns` is zero then the `wrapped` format only affects screen output. If `columns` is nonzero then file and pipe output is wrapped to that width as well.

#### `csv_fieldsep`

Specifies the field separator to be used in CSV output format. If the separator character appears in a field's value, that field is output within double quotes, following standard CSV rules. The default is a comma.

#### `expanded (or x)`

If *value* is specified it must be either `on` or `off`, which will enable or disable expanded mode, or `auto`. If *value* is omitted the command toggles between the on and off settings. When expanded mode is enabled, query results are displayed in two columns, with the column name on the left and the data on the right. This mode is useful if the data wouldn't fit on the screen in the normal "horizontal" mode. In the auto setting, the expanded mode is used whenever the query output has more than one column and is wider than the screen; otherwise, the regular mode is used. The auto setting is only effective in the aligned and wrapped formats. In other formats, it always behaves as if the expanded mode is off.

#### `fieldsep`

Specifies the field separator to be used in unaligned output format. That way one can create, for example, tab-separated output, which other programs might prefer. To set a tab as field separator, type `\pset fieldsep '\t'`. The default field separator is `'|'` (a vertical bar).

#### `fieldsep_zero`

Sets the field separator to use in unaligned output format to a zero byte.

#### `footer`

If *value* is specified it must be either `on` or `off` which will enable or disable display of the table footer (the `(n rows)` count). If *value* is omitted the command toggles footer display on or off.

#### `format`

Sets the output format to one of `aligned`, `asciidoc`, `csv`, `html`, `latex`, `latex-longtable`, `troff-ms`, `unaligned`, or `wrapped`. Unique abbreviations are allowed.

`aligned` format is the standard, human-readable, nicely formatted text output; this is the default.

`unaligned` format writes all columns of a row on one line, separated by the currently active field separator. This is useful for creating output that might be intended to be read in by other programs, for example, tab-separated or comma-separated format. However, the field separator character is not treated specially if it appears in a column's value; so CSV format may be better suited for such purposes.

`csv` format writes column values separated by commas, applying the quoting rules described in [RFC 4180](#). This output is compatible with the CSV format of the server's `COPY` command. A header line with column names is generated unless the `tuples_only` parameter is `on`. Titles and footers are not printed. Each row is terminated by the system-dependent end-of-line character, which is typically a single newline (`\n`) for Unix-like systems or a carriage return and newline sequence

---

(`\r\n`) for Microsoft Windows. Field separator characters other than comma can be selected with `\pset csv_fieldsep`.

`wrapped` format is like `aligned` but wraps wide data values across lines to make the output fit in the target column width. The target width is determined as described under the `columns` option. Note that `psql` will not attempt to wrap column header titles; therefore, `wrapped` format behaves the same as `aligned` if the total width needed for column headers exceeds the target.

The `asciidoc`, `html`, `latex`, `latex-longtable`, and `troff-ms` formats put out tables that are intended to be included in documents using the respective mark-up language. They are not complete documents! This might not be necessary in HTML, but in LaTeX you must have a complete document wrapper. The `latex` format uses LaTeX's `tabular` environment. The `latex-longtable` format requires the LaTeX `longtable` and `booktabs` packages.

#### `linestyle`

Sets the border line drawing style to one of `ascii`, `old-ascii`, or `unicode`. Unique abbreviations are allowed. (That would mean one letter is enough.) The default setting is `ascii`. This option only affects the `aligned` and `wrapped` output formats.

`ascii` style uses plain ASCII characters. Newlines in data are shown using a `+` symbol in the right-hand margin. When the `wrapped` format wraps data from one line to the next without a newline character, a dot (`.`) is shown in the right-hand margin of the first line, and again in the left-hand margin of the following line.

`old-ascii` style uses plain ASCII characters, using the formatting style used in PostgreSQL 8.4 and earlier. Newlines in data are shown using a `:` symbol in place of the left-hand column separator. When the data is wrapped from one line to the next without a newline character, a `;` symbol is used in place of the left-hand column separator.

`unicode` style uses Unicode box-drawing characters. Newlines in data are shown using a carriage return symbol in the right-hand margin. When the data is wrapped from one line to the next without a newline character, an ellipsis symbol is shown in the right-hand margin of the first line, and again in the left-hand margin of the following line.

When the `border` setting is greater than zero, the `linestyle` option also determines the characters with which the border lines are drawn. Plain ASCII characters work everywhere, but Unicode characters look nicer on displays that recognize them.

#### `null`

Sets the string to be printed in place of a null value. The default is to print nothing, which can easily be mistaken for an empty string. For example, one might prefer `\pset null '(null)'`.

#### `numericlocale`

If `value` is specified it must be either `on` or `off` which will enable or disable display of a locale-specific character to separate groups of digits to the left of the decimal marker. If `value` is omitted the command toggles between regular and locale-specific numeric output.

#### `pager`

Controls use of a pager program for query and `psql` help output. If the environment variable `PSQL_PAGER` or `PAGER` is set, the output is piped to the specified program. Otherwise a platform-dependent default program (such as `more`) is used.

When the `pager` option is `off`, the pager program is not used. When the `pager` option is `on`, the pager is used when appropriate, i.e., when the output is to a terminal and will not fit on the screen. The `pager` option can also be set to `always`, which causes the pager to be used for all terminal output regardless of whether it fits on the screen. `\pset pager` without a `value` toggles pager use on and off.

`pager_min_lines`

If `pager_min_lines` is set to a number greater than the page height, the pager program will not be called unless there are at least this many lines of output to show. The default setting is 0.

`recordsep`

Specifies the record (line) separator to use in unaligned output format. The default is a newline character.

`recordsep_zero`

Sets the record separator to use in unaligned output format to a zero byte.

`tableattr` (or `T`)

In HTML format, this specifies attributes to be placed inside the `table` tag. This could for example be `cellpadding` or `bgcolor`. Note that you probably don't want to specify `border` here, as that is already taken care of by `\pset border`. If no *value* is given, the table attributes are unset.

In `latex-longtable` format, this controls the proportional width of each column containing a left-aligned data type. It is specified as a whitespace-separated list of values, e.g., `'0.2 0.2 0.6'`. Unspecified output columns use the last specified value.

`title` (or `C`)

Sets the table title for any subsequently printed tables. This can be used to give your output descriptive tags. If no *value* is given, the title is unset.

`tuples_only` (or `t`)

If *value* is specified it must be either `on` or `off` which will enable or disable tuples-only mode. If *value* is omitted the command toggles between regular and tuples-only output. Regular output includes extra information such as column headers, titles, and various footers. In tuples-only mode, only actual table data is shown.

`unicode_border_linestyle`

Sets the border drawing style for the `unicode` line style to one of `single` or `double`.

`unicode_column_linestyle`

Sets the column drawing style for the `unicode` line style to one of `single` or `double`.

`unicode_header_linestyle`

Sets the header drawing style for the `unicode` line style to one of `single` or `double`.

Illustrations of how these different formats look can be seen in [Examples](#), below.

### Tip

There are various shortcut commands for `\pset`. See `\a`, `\C`, `\f`, `\H`, `\t`, `\T`, and `\x`.

`\q` or `\quit`

Quits the `psql` program. In a script file, only execution of that script is terminated.

`\qecho text [ ... ]`

This command is identical to `\echo` except that the output will be written to the query output channel, as set by `\o`.

`\r` or `\reset`

Resets (clears) the query buffer.

`\s` [ *filename* ]

Print psql's command line history to *filename*. If *filename* is omitted, the history is written to the standard output (using the pager if appropriate). This command is not available if psql was built without Readline support.

`\set` [ *name* [ *value* [ ... ] ] ]

Sets the psql variable *name* to *value*, or if more than one value is given, to the concatenation of all of them. If only one argument is given, the variable is set to an empty-string value. To unset a variable, use the `\unset` command.

`\set` without any arguments displays the names and values of all currently-set psql variables.

Valid variable names can contain letters, digits, and underscores. See [Variables](#) below for details. Variable names are case-sensitive.

Certain variables are special, in that they control psql's behavior or are automatically set to reflect connection state. These variables are documented in [Variables](#), below.

### Note

This command is unrelated to the SQL command [SET](#).

`\setenv` *name* [ *value* ]

Sets the environment variable *name* to *value*, or if the *value* is not supplied, unsets the environment variable. Example:

```
testdb=> \setenv PAGER less
testdb=> \setenv LESS -imx4F
```

`\sf`[+] *function\_description*

This command fetches and shows the definition of the named function or procedure, in the form of a CREATE OR REPLACE FUNCTION or CREATE OR REPLACE PROCEDURE command. The definition is printed to the current query output channel, as set by `\o`.

The target function can be specified by name alone, or by name and arguments, for example `foo(integer, text)`. The argument types must be given if there is more than one function of the same name.

If `+` is appended to the command name, then the output lines are numbered, with the first line of the function body being line 1.

Unlike most other meta-commands, the entire remainder of the line is always taken to be the argument(s) of `\sf`, and neither variable interpolation nor backquote expansion are performed in the arguments.

`\sv`[+] *view\_name*

This command fetches and shows the definition of the named view, in the form of a CREATE OR REPLACE VIEW command. The definition is printed to the current query output channel, as set by `\o`.

If `+` is appended to the command name, then the output lines are numbered from 1.

Unlike most other meta-commands, the entire remainder of the line is always taken to be the argument(s) of `\sv`, and neither variable interpolation nor backquote expansion are performed in the arguments.

- 
- `\t`
- Toggles the display of output column name headings and row count footer. This command is equivalent to `\pset tuples_only` and is provided for convenience.
- `\T table_options`
- Specifies attributes to be placed within the `table` tag in HTML output format. This command is equivalent to `\pset tableattr table_options`.
- `\timing [ on | off ]`
- With a parameter, turns displaying of how long each SQL statement takes on or off. Without a parameter, toggles the display between on and off. The display is in milliseconds; intervals longer than 1 second are also shown in minutes:seconds format, with hours and days fields added if needed.
- `\unset name`
- Unsets (deletes) the psql variable *name*.
- Most variables that control psql's behavior cannot be unset; instead, an `\unset` command is interpreted as setting them to their default values. See [Variables](#) below.
- `\w` or `\write filename`  
`\w` or `\write |command`
- Writes the current query buffer to the file *filename* or pipes it to the shell command *command*. If the current query buffer is empty, the most recently executed query is written instead.
- If the argument begins with `|`, then the entire remainder of the line is taken to be the *command* to execute, and neither variable interpolation nor backquote expansion are performed in it. The rest of the line is simply passed literally to the shell.
- `\warn text [ ... ]`
- This command is identical to `\echo` except that the output will be written to psql's standard error channel, rather than standard output.
- `\watch [ seconds ]`
- Repeatedly execute the current query buffer (as `\g` does) until interrupted or the query fails. Wait the specified number of seconds (default 2) between executions. Each query result is displayed with a header that includes the `\pset title` string (if any), the time as of query start, and the delay interval.
- If the current query buffer is empty, the most recently sent query is re-executed instead.
- `\x [ on | off | auto ]`
- Sets or toggles expanded table formatting mode. As such it is equivalent to `\pset expanded`.
- `\z [ pattern ]`
- Lists tables, views and sequences with their associated access privileges. If a *pattern* is specified, only tables, views and sequences whose names match the pattern are listed.
- This is an alias for `\dp` ("display privileges").
- `\! [ command ]`
- With no argument, escapes to a sub-shell; psql resumes when the sub-shell exits. With an argument, executes the shell command *command*.
- Unlike most other meta-commands, the entire remainder of the line is always taken to be the argument(s) of `\!`, and neither variable interpolation nor backquote expansion are performed in the arguments. The rest of the line is simply passed literally to the shell.

`\? [ topic ]`

Shows help information. The optional *topic* parameter (defaulting to `commands`) selects which part of `psql` is explained: `commands` describes `psql`'s backslash commands; `options` describes the command-line options that can be passed to `psql`; and `variables` shows help about `psql` configuration variables.

`\;`

Backslash-semicolon is not a meta-command in the same way as the preceding commands; rather, it simply causes a semicolon to be added to the query buffer without any further processing.

Normally, `psql` will dispatch a SQL command to the server as soon as it reaches the command-ending semicolon, even if more input remains on the current line. Thus for example entering

```
select 1; select 2; select 3;
```

will result in the three SQL commands being individually sent to the server, with each one's results being displayed before continuing to the next command. However, a semicolon entered as `\;` will not trigger command processing, so that the command before it and the one after are effectively combined and sent to the server in one request. So for example

```
select 1\; select 2\; select 3;
```

results in sending the three SQL commands to the server in a single request, when the non-backslashed semicolon is reached. The server executes such a request as a single transaction, unless there are explicit `BEGIN/COMMIT` commands included in the string to divide it into multiple transactions. (See [Section 50.2.2.1](#) for more details about how the server handles multi-query strings.) `psql` prints only the last query result it receives for each request; in this example, although all three `SELECTS` are indeed executed, `psql` only prints the 3.

## Patterns

The various `\d` commands accept a *pattern* parameter to specify the object name(s) to be displayed. In the simplest case, a pattern is just the exact name of the object. The characters within a pattern are normally folded to lower case, just as in SQL names; for example, `\dt FOO` will display the table named `foo`. As in SQL names, placing double quotes around a pattern stops folding to lower case. Should you need to include an actual double quote character in a pattern, write it as a pair of double quotes within a double-quote sequence; again this is in accord with the rules for SQL quoted identifiers. For example, `\dt "FOO"BAR` will display the table named `FOO"BAR` (not `foo"bar`). Unlike the normal rules for SQL names, you can put double quotes around just part of a pattern, for instance `\dt FOO"FOO"BAR` will display the table named `fooFOObar`.

Whenever the *pattern* parameter is omitted completely, the `\d` commands display all objects that are visible in the current schema search path — this is equivalent to using `*` as the pattern. (An object is said to be *visible* if its containing schema is in the search path and no object of the same kind and name appears earlier in the search path. This is equivalent to the statement that the object can be referenced by name without explicit schema qualification.) To see all objects in the database regardless of visibility, use `*.*` as the pattern.

Within a pattern, `*` matches any sequence of characters (including no characters) and `?` matches any single character. (This notation is comparable to Unix shell file name patterns.) For example, `\dt int*` displays tables whose names begin with `int`. But within double quotes, `*` and `?` lose these special meanings and are just matched literally.

A pattern that contains a dot (`.`) is interpreted as a schema name pattern followed by an object name pattern. For example, `\dt foo*.bar*` displays all tables whose table name includes `bar` that are in schemas whose schema name starts with `foo`. When no dot appears, then the pattern matches only objects that are visible in the current schema search path. Again, a dot within double quotes loses its special meaning and is matched literally.

Advanced users can use regular-expression notations such as character classes, for example `[0-9]` to match any digit. All regular expression special characters work as specified in [Section 9.7.3](#), except for

. which is taken as a separator as mentioned above, \* which is translated to the regular-expression notation .\*, ? which is translated to ., and \$ which is matched literally. You can emulate these pattern characters at need by writing ? for ., (R+|) for R\*, or (R|) for R?. \$ is not needed as a regular-expression character since the pattern must match the whole name, unlike the usual interpretation of regular expressions (in other words, \$ is automatically appended to your pattern). Write \* at the beginning and/or end if you don't wish the pattern to be anchored. Note that within double quotes, all regular expression special characters lose their special meanings and are matched literally. Also, the regular expression special characters are matched literally in operator name patterns (i.e., the argument of \do).

## Advanced Features

### Variables

psql provides variable substitution features similar to common Unix command shells. Variables are simply name/value pairs, where the value can be any string of any length. The name must consist of letters (including non-Latin letters), digits, and underscores.

To set a variable, use the psql meta-command \set. For example,

```
testdb=> \set foo bar
```

sets the variable foo to the value bar. To retrieve the content of the variable, precede the name with a colon, for example:

```
testdb=> \echo :foo
bar
```

This works in both regular SQL commands and meta-commands; there is more detail in [SQL Interpolation](#), below.

If you call \set without a second argument, the variable is set to an empty-string value. To unset (i.e., delete) a variable, use the command \unset. To show the values of all variables, call \set without any argument.

### Note

The arguments of \set are subject to the same substitution rules as with other commands. Thus you can construct interesting references such as \set :foo 'something' and get “soft links” or “variable variables” of Perl or PHP fame, respectively. Unfortunately (or fortunately?), there is no way to do anything useful with these constructs. On the other hand, \set bar :foo is a perfectly valid way to copy a variable.

A number of these variables are treated specially by psql. They represent certain option settings that can be changed at run time by altering the value of the variable, or in some cases represent changeable state of psql. By convention, all specially treated variables' names consist of all upper-case ASCII letters (and possibly digits and underscores). To ensure maximum compatibility in the future, avoid using such variable names for your own purposes.

Variables that control psql's behavior generally cannot be unset or set to invalid values. An \unset command is allowed but is interpreted as setting the variable to its default value. A \set command without a second argument is interpreted as setting the variable to on, for control variables that accept that value, and is rejected for others. Also, control variables that accept the values on and off will also accept other common spellings of Boolean values, such as true and false.

The specially treated variables are:

AUTOCOMMIT

When on (the default), each SQL command is automatically committed upon successful completion. To postpone commit in this mode, you must enter a BEGIN or START TRANSACTION SQL command. When off or unset, SQL commands are not committed until you explicitly issue COMMIT or END. The

autocommit-off mode works by issuing an implicit `BEGIN` for you, just before any command that is not already in a transaction block and is not itself a `BEGIN` or other transaction-control command, nor a command that cannot be executed inside a transaction block (such as `VACUUM`).

### Note

In autocommit-off mode, you must explicitly abandon any failed transaction by entering `ABORT` or `ROLLBACK`. Also keep in mind that if you exit the session without committing, your work will be lost.

### Note

The autocommit-on mode is Postgres Pro's traditional behavior, but autocommit-off is closer to the SQL spec. If you prefer autocommit-off, you might wish to set it in the system-wide `psqlrc` file or your `~/.psqlrc` file.

#### COMP\_KEYWORD\_CASE

Determines which letter case to use when completing an SQL key word. If set to `lower` or `upper`, the completed word will be in lower or upper case, respectively. If set to `preserve-lower` or `preserve-upper` (the default), the completed word will be in the case of the word already entered, but words being completed without anything entered will be in lower or upper case, respectively.

#### DBNAME

The name of the database you are currently connected to. This is set every time you connect to a database (including program start-up), but can be changed or unset.

#### ECHO

If set to `all`, all nonempty input lines are printed to standard output as they are read. (This does not apply to lines read interactively.) To select this behavior on program start-up, use the switch `-a`. If set to `queries`, `psql` prints each query to standard output as it is sent to the server. The switch to select this behavior is `-e`. If set to `errors`, then only failed queries are displayed on standard error output. The switch for this behavior is `-b`. If set to `none` (the default), then no queries are displayed.

#### ECHO\_HIDDEN

When this variable is set to `on` and a backslash command queries the database, the query is first shown. This feature helps you to study Postgres Pro internals and provide similar functionality in your own programs. (To select this behavior on program start-up, use the switch `-E`.) If you set this variable to the value `noexec`, the queries are just shown but are not actually sent to the server and executed. The default value is `off`.

#### ENCODING

The current client character set encoding. This is set every time you connect to a database (including program start-up), and when you change the encoding with `\encoding`, but it can be changed or unset.

#### ERROR

`true` if the last SQL query failed, `false` if it succeeded. See also `SQLSTATE`.

#### FETCH\_COUNT

If this variable is set to an integer value greater than zero, the results of `SELECT` queries are fetched and displayed in groups of that many rows, rather than the default behavior of collecting the entire result set before display. Therefore only a limited amount of memory is used, regardless of the size of

the result set. Settings of 100 to 1000 are commonly used when enabling this feature. Keep in mind that when using this feature, a query might fail after having already displayed some rows.

### Tip

Although you can use any output format with this feature, the default `aligned` format tends to look bad because each group of `FETCH_COUNT` rows will be formatted separately, leading to varying column widths across the row groups. The other output formats work better.

#### HIDE\_TABLEAM

If this variable is set to `true`, a table's access method details are not displayed. This is mainly useful for regression tests.

#### HISTCONTROL

If this variable is set to `ignoreSpace`, lines which begin with a space are not entered into the history list. If set to a value of `ignoreDups`, lines matching the previous history line are not entered. A value of `ignoreBoth` combines the two options. If set to `none` (the default), all lines read in interactive mode are saved on the history list.

### Note

This feature was shamelessly plagiarized from Bash.

#### HISTFILE

The file name that will be used to store the history list. If unset, the file name is taken from the `PSQL_HISTORY` environment variable. If that is not set either, the default is `~/.psql_history`, or `%APPDATA%\postgresql\psql_history` on Windows. For example, putting:

```
\set HISTFILE ~/.psql_history- :DBNAME
```

in `~/.psqlrc` will cause `psql` to maintain a separate history for each database.

### Note

This feature was shamelessly plagiarized from Bash.

#### HISTSIZE

The maximum number of commands to store in the command history (default 500). If set to a negative value, no limit is applied.

### Note

This feature was shamelessly plagiarized from Bash.

#### HOST

The database server host you are currently connected to. This is set every time you connect to a database (including program start-up), but can be changed or unset.

#### IGNOREEOF

If set to 1 or less, sending an EOF character (usually **Control+D**) to an interactive session of `psql` will terminate the application. If set to a larger numeric value, that many consecutive EOF characters must be typed to make an interactive session terminate. If the variable is set to a non-numeric value, it is interpreted as 10. The default is 0.

**Note**

This feature was shamelessly plagiarized from Bash.

## LASTOID

The value of the last affected OID, as returned from an `INSERT` or `\lo_import` command. This variable is only guaranteed to be valid until after the result of the next SQL command has been displayed. Postgres Pro servers since version 12 do not support OID system columns anymore, thus `LASTOID` will always be 0 following `INSERT` when targeting such servers.

## LAST\_ERROR\_MESSAGE

## LAST\_ERROR\_SQLSTATE

The primary error message and associated `SQLSTATE` code for the most recent failed query in the current `psql` session, or an empty string and `00000` if no error has occurred in the current session.

## ON\_ERROR\_ROLLBACK

When set to `on`, if a statement in a transaction block generates an error, the error is ignored and the transaction continues. When set to `interactive`, such errors are only ignored in interactive sessions, and not when reading script files. When set to `off` (the default), a statement in a transaction block that generates an error aborts the entire transaction. The error rollback mode works by issuing an implicit `SAVEPOINT` for you, just before each command that is in a transaction block, and then rolling back to the savepoint if the command fails.

## ON\_ERROR\_STOP

By default, command processing continues after an error. When this variable is set to `on`, processing will instead stop immediately. In interactive mode, `psql` will return to the command prompt; otherwise, `psql` will exit, returning error code 3 to distinguish this case from fatal error conditions, which are reported using error code 1. In either case, any currently running scripts (the top-level script, if any, and any other scripts which it may have invoked) will be terminated immediately. If the top-level command string contained multiple SQL commands, processing will stop with the current command.

## PORT

The database server port to which you are currently connected. This is set every time you connect to a database (including program start-up), but can be changed or unset.

## PROMPT1

## PROMPT2

## PROMPT3

These specify what the prompts `psql` issues should look like. See [Prompting](#) below.

## QUIET

Setting this variable to `on` is equivalent to the command line option `-q`. It is probably not too useful in interactive mode.

## ROW\_COUNT

The number of rows returned or affected by the last SQL query, or 0 if the query failed or did not report a row count.

## SERVER\_VERSION\_NAME

## SERVER\_VERSION\_NUM

The server's version number as a string, for example `9.6.2`, `10.1` or `11beta1`, and in numeric form, for example `90602` or `100001`. These are set every time you connect to a database (including program start-up), but can be changed or unset.

## SHOW\_CONTEXT

This variable can be set to the values `never`, `errors`, or `always` to control whether `CONTEXT` fields are displayed in messages from the server. The default is `errors` (meaning that context will be shown in error messages, but not in notice or warning messages). This setting has no effect when `VERBOSITY` is set to `terse` or `sqlstate`. (See also `\errverbose`, for use when you want a verbose version of the error you just got.)

## SINGLELINE

Setting this variable to `on` is equivalent to the command line option `-s`.

## SINGLESTEP

Setting this variable to `on` is equivalent to the command line option `-s`.

## SQLSTATE

The error code (see [Appendix A](#)) associated with the last SQL query's failure, or `00000` if it succeeded.

## USER

The database user you are currently connected as. This is set every time you connect to a database (including program start-up), but can be changed or unset.

## VERBOSITY

This variable can be set to the values `default`, `verbose`, `terse`, or `sqlstate` to control the verbosity of error reports. (See also `\errverbose`, for use when you want a verbose version of the error you just got.)

## VERSION

## VERSION\_NAME

## VERSION\_NUM

These variables are set at program start-up to reflect `psql`'s version, respectively as a verbose string, a short string (e.g., `9.6.2`, `10.1`, or `11beta1`), and a number (e.g., `90602` or `100001`). They can be changed or unset.

## SQL Interpolation

A key feature of `psql` variables is that you can substitute (“interpolate”) them into regular SQL statements, as well as the arguments of meta-commands. Furthermore, `psql` provides facilities for ensuring that variable values used as SQL literals and identifiers are properly quoted. The syntax for interpolating a value without any quoting is to prepend the variable name with a colon (`:`). For example,

```
testdb=> \set foo 'my_table'
testdb=> SELECT * FROM :foo;
```

would query the table `my_table`. Note that this may be unsafe: the value of the variable is copied literally, so it can contain unbalanced quotes, or even backslash commands. You must make sure that it makes sense where you put it.

When a value is to be used as an SQL literal or identifier, it is safest to arrange for it to be quoted. To quote the value of a variable as an SQL literal, write a colon followed by the variable name in single quotes. To quote the value as an SQL identifier, write a colon followed by the variable name in double quotes. These constructs deal correctly with quotes and other special characters embedded within the variable value. The previous example would be more safely written this way:

```
testdb=> \set foo 'my_table'
testdb=> SELECT * FROM :"foo";
```

Variable interpolation will not be performed within quoted SQL literals and identifiers. Therefore, a construction such as `':foo'` doesn't work to produce a quoted literal from a variable's value (and it would be unsafe if it did work, since it wouldn't correctly handle quotes embedded in the value).

One example use of this mechanism is to copy the contents of a file into a table column. First load the file into a variable and then interpolate the variable's value as a quoted string:

```
testdb=> \set content `cat my_file.txt`
testdb=> INSERT INTO my_table VALUES (: 'content');
```

(Note that this still won't work if `my_file.txt` contains NUL bytes. psql does not support embedded NUL bytes in variable values.)

Since colons can legally appear in SQL commands, an apparent attempt at interpolation (that is, `:name`, `:'name'`, or `:"name"`) is not replaced unless the named variable is currently set. In any case, you can escape a colon with a backslash to protect it from substitution.

The `:{?name}` special syntax returns TRUE or FALSE depending on whether the variable exists or not, and is thus always substituted, unless the colon is backslash-escaped.

The colon syntax for variables is standard SQL for embedded query languages, such as ECPG. The colon syntaxes for array slices and type casts are Postgres Pro extensions, which can sometimes conflict with the standard usage. The colon-quote syntax for escaping a variable's value as an SQL literal or identifier is a psql extension.

## Prompting

The prompts psql issues can be customized to your preference. The three variables `PROMPT1`, `PROMPT2`, and `PROMPT3` contain strings and special escape sequences that describe the appearance of the prompt. Prompt 1 is the normal prompt that is issued when psql requests a new command. Prompt 2 is issued when more input is expected during command entry, for example because the command was not terminated with a semicolon or a quote was not closed. Prompt 3 is issued when you are running an SQL `COPY FROM STDIN` command and you need to type in a row value on the terminal.

The value of the selected prompt variable is printed literally, except where a percent sign (`%`) is encountered. Depending on the next character, certain other text is substituted instead. Defined substitutions are:

`%M`  
The full host name (with domain name) of the database server, or `[local]` if the connection is over a Unix domain socket, or `[local:/dir/name]`, if the Unix domain socket is not at the compiled in default location.

`%m`  
The host name of the database server, truncated at the first dot, or `[local]` if the connection is over a Unix domain socket.

`%>`  
The port number at which the database server is listening.

`%n`  
The database session user name. (The expansion of this value might change during a database session as the result of the command `SET SESSION AUTHORIZATION`.)

`%/`  
The name of the current database.

`%~`  
Like `%/`, but the output is `~` (tilde) if the database is your default database.

`%#`  
If the session user is a database superuser, then a `#`, otherwise a `>`. (The expansion of this value might change during a database session as the result of the command `SET SESSION AUTHORIZATION`.)

`%p`

The process ID of the backend currently connected to.

`%R`

In prompt 1 normally =, but @ if the session is in an inactive branch of a conditional block, or ^ if in single-line mode, or ! if the session is disconnected from the database (which can happen if `\connect` fails). In prompt 2 `%R` is replaced by a character that depends on why psql expects more input: - if the command simply wasn't terminated yet, but \* if there is an unfinished `/* ... */` comment, a single quote if there is an unfinished quoted string, a double quote if there is an unfinished quoted identifier, a dollar sign if there is an unfinished dollar-quoted string, or ( if there is an unmatched left parenthesis. In prompt 3 `%R` doesn't produce anything.

`%x`

Transaction status: an empty string when not in a transaction block, or \* when in a transaction block, or ! when in a failed transaction block, or ? when the transaction state is indeterminate (for example, because there is no connection).

`%l`

The line number inside the current statement, starting from 1.

`%digits`

The character with the indicated octal code is substituted.

`%:name:`

The value of the psql variable *name*. See [Variables](#), above, for details.

`%`command``

The output of *command*, similar to ordinary “back-tick” substitution.

`%[ ... %]`

Prompts can contain terminal control characters which, for example, change the color, background, or style of the prompt text, or change the title of the terminal window. In order for the line editing features of Readline to work properly, these non-printing control characters must be designated as invisible by surrounding them with `%[` and `;%]`. Multiple pairs of these can occur within the prompt. For example:

```
testdb=> \set PROMPT1 '%[%033[1;33;40m%]n@%/%R%[%033[0m%]## '
```

results in a boldfaced (1;) yellow-on-black (33;40) prompt on VT100-compatible, color-capable terminals.

`%w`

Whitespace of the same width as the most recent output of `PROMPT1`. This can be used as a `PROMPT2` setting, so that multi-line statements are aligned with the first line, but there is no visible secondary prompt.

To insert a percent sign into your prompt, write `%%`. The default prompts are `'%/%R%x%# '` for prompts 1 and 2, and `'>> '` for prompt 3.

### Note

This feature was shamelessly plagiarized from tcsh.

## Command-Line Editing

psql supports the Readline library for convenient line editing and retrieval. The command history is automatically saved when psql exits and is reloaded when psql starts up. Tab-completion is also supported, although the completion logic makes no claim to be an SQL parser. The queries generated by tab-completion can also interfere with other SQL commands, e.g., `SET TRANSACTION ISOLATION LEVEL`. If for some reason you do not like the tab completion, you can turn it off by putting this in a file named `.inputrc` in your home directory:

```
$if psql
set disable-completion on
$endif
```

(This is not a psql but a Readline feature. Read its documentation for further details.)

## Environment

### COLUMNS

If `\pset columns` is zero, controls the width for the `wrapped` format and width for determining if wide output requires the pager or should be switched to the vertical format in expanded auto mode.

PGDATABASE  
PGHOST  
PGPORT  
PGUSER

Default connection parameters (see [Section 31.14](#)).

### PG\_COLOR

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

PSQL\_EDITOR  
EDITOR  
VISUAL

Editor used by the `\e`, `\ef`, and `\ev` commands. These variables are examined in the order listed; the first that is set is used. If none of them is set, the default is to use `vi` on Unix systems or `notepad.exe` on Windows systems.

### PSQL\_EDITOR\_LINENUMBER\_ARG

When `\e`, `\ef`, or `\ev` is used with a line number argument, this variable specifies the command-line argument used to pass the starting line number to the user's editor. For editors such as Emacs or `vi`, this is a plus sign. Include a trailing space in the value of the variable if there needs to be space between the option name and the line number. Examples:

```
PSQL_EDITOR_LINENUMBER_ARG='+'
PSQL_EDITOR_LINENUMBER_ARG='--line '
```

The default is `+` on Unix systems (corresponding to the default editor `vi`, and useful for many other common editors); but there is no default on Windows systems.

### PSQL\_HISTORY

Alternative location for the command history file. Tilde (`~`) expansion is performed.

PSQL\_PAGER  
PAGER

If a query's results do not fit on the screen, they are piped through this command. Typical values are `more` or `less`. Use of the pager can be disabled by setting `PSQL_PAGER` or `PAGER` to an empty string, or by adjusting the pager-related options of the `\pset` command. These variables are examined in

the order listed; the first that is set is used. If none of them is set, the default is to use `more` on most platforms, but `less` on Cygwin.

**PSQLRC**

Alternative location of the user's `.psqlrc` file. Tilde (`~`) expansion is performed.

**SHELL**

Command executed by the `\!` command.

**TMPDIR**

Directory for storing temporary files. The default is `/tmp`.

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by `libpq` (see [Section 31.14](#)).

## Files

**psqlrc and ~/.psqlrc**

Unless it is passed an `-x` option, `psql` attempts to read and execute commands from the system-wide startup file (`psqlrc`) and then the user's personal startup file (`~/.psqlrc`), after connecting to the database but before accepting normal commands. These files can be used to set up the client and/or the server to taste, typically with `\set` and `SET` commands.

The system-wide startup file is named `psqlrc` and is sought in the installation's "system configuration" directory, which is most reliably identified by running `pg_config --sysconfdir`. By default this directory will be `../etc/` relative to the directory containing the Postgres Pro executables. The name of this directory can be set explicitly via the `PGSYSCONFDIR` environment variable.

The user's personal startup file is named `.psqlrc` and is sought in the invoking user's home directory. On Windows, which lacks such a concept, the personal startup file is named `%APPDATA%\postgresql\psqlrc.conf`. The location of the user's startup file can be set explicitly via the `PSQLRC` environment variable.

Both the system-wide startup file and the user's personal startup file can be made `psql`-version-specific by appending a dash and the Postgres Pro major or minor release number to the file name, for example `~/.psqlrc-9.2` or `~/.psqlrc-9.2.5`. The most specific version-matching file will be read in preference to a non-version-specific file.

**.psql\_history**

The command-line history is stored in the file `~/.psql_history`, or `%APPDATA%\postgresql\psql_history` on Windows.

The location of the history file can be set explicitly via the `HISTFILE` `psql` variable or the `PSQL_HISTORY` environment variable.

## Notes

- `psql` works best with servers of the same or an older major version. Backslash commands are particularly likely to fail if the server is of a newer version than `psql` itself. However, backslash commands of the `\d` family should work with servers of versions back to 7.4, though not necessarily with servers newer than `psql` itself. The general functionality of running SQL commands and displaying query results should also work with servers of a newer major version, but this cannot be guaranteed in all cases.

If you want to use `psql` to connect to several servers of different major versions, it is recommended that you use the newest version of `psql`. Alternatively, you can keep around a copy of `psql` from each

major version and be sure to use the version that matches the respective server. But in practice, this additional complication should not be necessary.

- Before Postgres Pro 9.6, the `-c` option implied `-X` (`--no-psqlrc`); this is no longer the case.
- Before PostgreSQL 8.4, `psql` allowed the first argument of a single-letter backslash command to start directly after the command, without intervening whitespace. Now, some whitespace is required.

## Notes for Windows Users

`psql` is built as a “console application”. Since the Windows console windows use a different encoding than the rest of the system, you must take special care when using 8-bit characters within `psql`. If `psql` detects a problematic console code page, it will warn you at startup. To change the console code page, two things are necessary:

- Set the code page by entering `cmd.exe /c chcp 1252`. (1252 is a code page that is appropriate for German; replace it with your value.) If you are using Cygwin, you can put this command in `/etc/profile`.
- Set the console font to `Lucida Console`, because the raster font does not work with the ANSI code page.

By default, `psql` works in the UTF-8 encoding and uses Windows Unicode API for console output. The console code page must be set to 65001 to ensure the correct display of all characters supported by your Windows console font.

Postgres Pro Windows installer ships the `less.exe` pager with UTF-8 support and provides a shortcut that opens the console window with `Lucida Console` font and `codepage 65001` settings. If you use a different pager, make sure it also supports UTF-8.

You can override the default `psql` encoding by setting the `PGCLIENTENCODING` environment variable.

## Examples

The first example shows how to spread a command over several lines of input. Notice the changing prompt:

```
testdb=> CREATE TABLE my_table (
testdb(>   first integer not null default 0,
testdb(>   second text)
testdb-> ;
CREATE TABLE
```

Now look at the table definition again:

```
testdb=> \d my_table
          Table "public.my_table"
  Column | Type   | Collation | Nullable | Default
-----+-----+-----+-----+-----
  first  | integer |           | not null | 0
  second | text    |           |          |
```

Now we change the prompt to something more interesting:

```
testdb=> \set PROMPT1 '%n@m %~%R%# '
peter@localhost testdb=>
```

Let's assume you have filled the table with data and want to take a look at it:

```
peter@localhost testdb=> SELECT * FROM my_table;
  first | second
-----+-----
    1  | one
```

```

2 | two
3 | three
4 | four
(4 rows)

```

You can display tables in different ways by using the `\pset` command:

```

peter@localhost testdb=> \pset border 2
Border style is 2.
peter@localhost testdb=> SELECT * FROM my_table;
+-----+-----+
| first | second |
+-----+-----+
|      1 | one    |
|      2 | two    |
|      3 | three  |
|      4 | four   |
+-----+-----+
(4 rows)

```

```

peter@localhost testdb=> \pset border 0
Border style is 0.
peter@localhost testdb=> SELECT * FROM my_table;
first second
-----
1 one
2 two
3 three
4 four
(4 rows)

```

```

peter@localhost testdb=> \pset border 1
Border style is 1.
peter@localhost testdb=> \pset format csv
Output format is csv.
peter@localhost testdb=> \pset tuples_only
Tuples only is on.
peter@localhost testdb=> SELECT second, first FROM my_table;
one,1
two,2
three,3
four,4
peter@localhost testdb=> \pset format unaligned
Output format is unaligned.
peter@localhost testdb=> \pset fieldsep '\t'
Field separator is "  ".
peter@localhost testdb=> SELECT second, first FROM my_table;
one      1
two      2
three    3
four     4

```

Alternatively, use the short commands:

```

peter@localhost testdb=> \a \t \x
Output format is aligned.
Tuples only is off.
Expanded display is on.
peter@localhost testdb=> SELECT * FROM my_table;
-[ RECORD 1 ]-

```

```

first | 1
second | one
-[ RECORD 2 ]-
first | 2
second | two
-[ RECORD 3 ]-
first | 3
second | three
-[ RECORD 4 ]-
first | 4
second | four

```

Also, these output format options can be set for just one query by using `\g`:

```

peter@localhost testdb=> SELECT * FROM my_table
peter@localhost testdb-> \g (format=aligned tuples_only=off expanded=on)
-[ RECORD 1 ]-
first | 1
second | one
-[ RECORD 2 ]-
first | 2
second | two
-[ RECORD 3 ]-
first | 3
second | three
-[ RECORD 4 ]-
first | 4
second | four

```

When suitable, query results can be shown in a crosstab representation with the `\crosstabview` command:

```

testdb=> SELECT first, second, first > 2 AS gt2 FROM my_table;
  first | second | gt2
-----+-----+-----
      1 | one    | f
      2 | two    | f
      3 | three  | t
      4 | four   | t
(4 rows)

```

```

testdb=> \crosstabview first second
  first | one | two | three | four
-----+-----+-----+-----+-----
      1 | f   |     |       |
      2 |     | f   |       |
      3 |     |     | t     |
      4 |     |     |       | t
(4 rows)

```

This second example shows a multiplication table with rows sorted in reverse numerical order and columns with an independent, ascending numerical order.

```

testdb=> SELECT t1.first as "A", t2.first+100 AS "B", t1.first*(t2.first+100) as "AxB",
testdb(> row_number() over(order by t2.first) AS ord
testdb(> FROM my_table t1 CROSS JOIN my_table t2 ORDER BY 1 DESC
testdb(> \crosstabview "A" "B" "AxB" ord
  A | 101 | 102 | 103 | 104
---+---+---+---+---
  4 | 404 | 408 | 412 | 416

```

```
3 | 303 | 306 | 309 | 312
2 | 202 | 204 | 206 | 208
1 | 101 | 102 | 103 | 104
(4 rows)
```

---

# reindexdb

reindexdb — reindex a Postgres Pro database

## Synopsis

```
reindexdb [connection-option...] [option...] [-S | --schema schema] ... [-t | --table table] ... [-i | --index index] ... [dbname]
```

```
reindexdb [connection-option...] [option...] -a | --all
```

```
reindexdb [connection-option...] [option...] -s | --system [dbname]
```

## Description

reindexdb is a utility for rebuilding indexes in a Postgres Pro database.

reindexdb is a wrapper around the SQL command [REINDEX](#). There is no effective difference between reindexing databases via this utility and via other methods for accessing the server.

## Options

reindexdb accepts the following command-line arguments:

```
-a  
--all
```

Reindex all databases.

```
--concurrently
```

Use the `CONCURRENTLY` option. See [REINDEX](#), where all the caveats of this option are explained in detail.

```
[-d] dbname  
[--dbname=] dbname
```

Specifies the name of the database to be reindexed, when `-a/--all` is not used. If this is not specified, the database name is read from the environment variable `PGDATABASE`. If that is not set, the user name specified for the connection is used. The *dbname* can be a [connection string](#). If so, connection string parameters will override any conflicting command line options.

```
-e  
--echo
```

Echo the commands that reindexdb generates and sends to the server.

```
-i index  
--index=index
```

Recreate *index* only. Multiple indexes can be recreated by writing multiple `-i` switches.

```
-j njobs  
--jobs=njobs
```

Execute the reindex commands in parallel by running *njobs* commands simultaneously. This option may reduce the processing time but it also increases the load on the database server.

reindexdb will open *njobs* connections to the database, so make sure your [max\\_connections](#) setting is high enough to accommodate all connections.

Note that this option is incompatible with the `--index` and `--system` options.

-q  
--quiet

Do not display progress messages.

-s  
--system

Reindex database's system catalogs only.

-S *schema*  
--schema=*schema*

Reindex *schema* only. Multiple schemas can be reindexed by writing multiple -s switches.

-t *table*  
--table=*table*

Reindex *table* only. Multiple tables can be reindexed by writing multiple -t switches.

-v  
--verbose

Print detailed information during processing.

-V  
--version

Print the reindexdb version and exit.

-?  
--help

Show help about reindexdb command line arguments, and exit.

reindexdb also accepts the following command-line arguments for connection parameters:

-h *host*  
--host=*host*

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

-p *port*  
--port=*port*

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

-U *username*  
--username=*username*

User name to connect as.

-w  
--no-password

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

-W  
--password

Force reindexdb to prompt for a password before connecting to a database.

This option is never essential, since `reindexdb` will automatically prompt for a password if the server demands password authentication. However, `reindexdb` will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-w` to avoid the extra connection attempt.

`--maintenance-db=dbname`

Specifies the name of the database to connect to to discover which databases should be reindexed, when `-a/--all` is used. If not specified, the `postgres` database will be used, or if that does not exist, `template1` will be used. This can be a [connection string](#). If so, connection string parameters will override any conflicting command line options. Also, connection string parameters other than the database name itself will be re-used when connecting to other databases.

## Environment

PGDATABASE  
PGHOST  
PGPORT  
PGUSER

Default connection parameters

PG\_COLOR

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by `libpq` (see [Section 31.14](#)).

## Diagnostics

In case of difficulty, see [REINDEX](#) and [psql](#) for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the `libpq` front-end library will apply.

## Notes

`reindexdb` might need to connect several times to the Postgres Pro server, asking for a password each time. It is convenient to have a `~/ .pgpass` file in such cases. See [Section 31.15](#) for more information.

## Examples

To reindex the database `test`:

```
$ reindexdb test
```

To reindex the table `foo` and the index `bar` in a database named `abcd`:

```
$ reindexdb --table=foo --index=bar abcd
```

# vacuumdb

vacuumdb — garbage-collect and analyze a Postgres Pro database

## Synopsis

```
vacuumdb [connection-option...] [option...] [-t | --table table [( column [,...] )] ] ... [dbname]
```

```
vacuumdb [connection-option...] [option...] -a | --all
```

## Description

vacuumdb is a utility for cleaning a Postgres Pro database. vacuumdb will also generate internal statistics used by the Postgres Pro query optimizer.

vacuumdb is a wrapper around the SQL command **VACUUM**. There is no effective difference between vacuuming and analyzing databases via this utility and via other methods for accessing the server.

## Options

vacuumdb accepts the following command-line arguments:

-a  
--all

Vacuum all databases.

[-d] *dbname*  
[--dbname=] *dbname*

Specifies the name of the database to be cleaned or analyzed, when *-a/--all* is not used. If this is not specified, the database name is read from the environment variable `PGDATABASE`. If that is not set, the user name specified for the connection is used. The *dbname* can be a [connection string](#). If so, connection string parameters will override any conflicting command line options.

--disable-page-skipping

Disable skipping pages based on the contents of the visibility map.

<p style="text-align: center;"><b>Note</b></p> <p style="text-align: center;">This option is only available for servers running Postgres Pro 9.6 and later.</p>
---

-e  
--echo

Echo the commands that vacuumdb generates and sends to the server.

-f  
--full

Perform “full” vacuuming.

-F  
--freeze

Aggressively “freeze” tuples.

-j *njobs*  
--jobs=*njobs*

Execute the vacuum or analyze commands in parallel by running *njobs* commands simultaneously. This option may reduce the processing time but it also increases the load on the database server.

vacuumdb will open *njobs* connections to the database, so make sure your [max\\_connections](#) setting is high enough to accommodate all connections.

Note that using this mode together with the `-f` (FULL) option might cause deadlock failures if certain system catalogs are processed in parallel.

`--min-mxid-age mxid_age`

Only execute the vacuum or analyze commands on tables with a multixact ID age of at least *mxid\_age*. This setting is useful for prioritizing tables to process to prevent multixact ID wraparound (see [Section 23.1.5.1](#)).

For the purposes of this option, the multixact ID age of a relation is the greatest of the ages of the main relation and its associated TOAST table, if one exists. Since the commands issued by vacuumdb will also process the TOAST table for the relation if necessary, it does not need to be considered separately.

### Note

This option is only available for servers running Postgres Pro 9.6 and later.

`--min-xid-age xid_age`

Only execute the vacuum or analyze commands on tables with a transaction ID age of at least *xid\_age*. This setting is useful for prioritizing tables to process to prevent transaction ID wraparound (see [Section 23.1.5](#)).

For the purposes of this option, the transaction ID age of a relation is the greatest of the ages of the main relation and its associated TOAST table, if one exists. Since the commands issued by vacuumdb will also process the TOAST table for the relation if necessary, it does not need to be considered separately.

### Note

This option is only available for servers running Postgres Pro 9.6 and later.

`-P parallel_workers`

`--parallel=parallel_workers`

Specify the number of parallel workers for *parallel vacuum*. This allows the vacuum to leverage multiple CPUs to process indexes. See [VACUUM](#).

### Note

This option is only available for servers running PostgreSQL 13 and later.

`-q`

`--quiet`

Do not display progress messages.

`--skip-locked`

Skip relations that cannot be immediately locked for processing.

### Note

This option is only available for servers running Postgres Pro 12 and later.

```
-t table [ (column [,...]) ]
--table=table [ (column [,...]) ]
```

Clean or analyze *table* only. Column names can be specified only in conjunction with the `--analyze` or `--analyze-only` options. Multiple tables can be vacuumed by writing multiple `-t` switches.

### Tip

If you specify columns, you probably have to escape the parentheses from the shell. (See examples below.)

```
-v
--verbose
```

Print detailed information during processing.

```
-V
--version
```

Print the vacuumdb version and exit.

```
-z
--analyze
```

Also calculate statistics for use by the optimizer.

```
-Z
--analyze-only
```

Only calculate statistics for use by the optimizer (no vacuum).

```
--analyze-in-stages
```

Only calculate statistics for use by the optimizer (no vacuum), like `--analyze-only`. Run several (currently three) stages of analyze with different configuration settings, to produce usable statistics faster.

This option is useful to analyze a database that was newly populated from a restored dump or by `pg_upgrade`. This option will try to create some statistics as fast as possible, to make the database usable, and then produce full statistics in the subsequent stages.

```
-?
--help
```

Show help about vacuumdb command line arguments, and exit.

vacuumdb also accepts the following command-line arguments for connection parameters:

```
-h host
--host=host
```

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

```
-p port
--port=port
```

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

```
-U username
--username=username
```

User name to connect as.

`-w`  
`--no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`  
`--password`

Force vacuumdb to prompt for a password before connecting to a database.

This option is never essential, since vacuumdb will automatically prompt for a password if the server demands password authentication. However, vacuumdb will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-w` to avoid the extra connection attempt.

`--maintenance-db=dbname`

Specifies the name of the database to connect to to discover which databases should be vacuumed, when `-a/--all` is used. If not specified, the `postgres` database will be used, or if that does not exist, `template1` will be used. This can be a [connection string](#). If so, connection string parameters will override any conflicting command line options. Also, connection string parameters other than the database name itself will be re-used when connecting to other databases.

## Environment

`PGDATABASE`  
`PGHOST`  
`PGPORT`  
`PGUSER`

Default connection parameters

`PG_COLOR`

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by libpq (see [Section 31.14](#)).

## Diagnostics

In case of difficulty, see [VACUUM](#) and [psql](#) for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

## Notes

vacuumdb might need to connect several times to the Postgres Pro server, asking for a password each time. It is convenient to have a `~/ .pgpass` file in such cases. See [Section 31.15](#) for more information.

## Examples

To clean the database `test`:

```
$ vacuumdb test
```

To clean and analyze for the optimizer a database named `bigdb`:

```
$ vacuumdb --analyze bigdb
```

To clean a single table `foo` in a database named `xyzzzy`, and analyze a single column `bar` of the table for the optimizer:

```
$ vacuumdb --analyze --verbose --table='foo(bar)' xyzy
```

# Postgres Pro Server Applications

This part contains reference information for Postgres Pro server applications and support utilities. These commands can only be run usefully on the host where the database server resides. Other utility programs are listed in [Postgres Pro Client Applications](#).

---

# initdb

initdb — create a new Postgres Pro database cluster

## Synopsis

```
initdb [option...] [ --pgdata | -D ] directory
```

## Description

`initdb` creates a new Postgres Pro database cluster. A database cluster is a collection of databases that are managed by a single server instance.

Creating a database cluster consists of creating the directories in which the database data will live, generating the shared catalog tables (tables that belong to the whole cluster rather than to any particular database), and creating the `template1` and `postgres` databases. When you later create a new database, everything in the `template1` database is copied. (Therefore, anything installed in `template1` is automatically copied into each database created later.) The `postgres` database is a default database meant for use by users, utilities and third party applications.

Although `initdb` will attempt to create the specified data directory, it might not have permission if the parent directory of the desired data directory is root-owned. To initialize in such a setup, create an empty data directory as root, then use `chown` to assign ownership of that directory to the database user account, then `su` to become the database user to run `initdb`.

`initdb` must be run as the user that will own the server process, because the server needs to have access to the files and directories that `initdb` creates. Since the server cannot be run as root, you must not run `initdb` as root either. (It will in fact refuse to do so.)

For security reasons the new cluster created by `initdb` will only be accessible by the cluster owner by default. The `--allow-group-access` option allows any user in the same group as the cluster owner to read files in the cluster. This is useful for performing backups as a non-privileged user.

`initdb` initializes the database cluster's default locale and character set encoding. The character set encoding, collation order (`LC_COLLATE`) and character set classes (`LC_CTYPE`, e.g., upper, lower, digit) can be set separately for a database when it is created. `initdb` determines those settings for the `template1` database, which will serve as the default for all other databases.

To alter the default collation order or character set classes, use the `--lc-collate` and `--lc-ctype` options. Collation orders other than `C` or `POSIX` also have a performance penalty. For these reasons it is important to choose the right locale when running `initdb`.

The remaining locale categories can be changed later when the server is started. You can also use `--locale` to set the default for all locale categories, including collation order and character set classes. All server locale values (`lc_*`) can be displayed via `SHOW ALL`. More details can be found in [Section 22.1](#).

To alter the default encoding, use the `--encoding`. More details can be found in [Section 22.3](#).

## Options

```
-A authmethod  
--auth=authmethod
```

This option specifies the default authentication method for local users used in `pg_hba.conf` (`host` and `local` lines). `initdb` will prepopulate `pg_hba.conf` entries using the specified authentication method for non-replication as well as replication connections.

Do not use `trust` unless you trust all local users on your system. `trust` is the default for ease of installation.

`--auth-host=authmethod`

This option specifies the authentication method for local users via TCP/IP connections used in `pg_hba.conf` (host lines).

`--auth-local=authmethod`

This option specifies the authentication method for local users via Unix-domain socket connections used in `pg_hba.conf` (local lines).

`-D directory`

`--pgdata=directory`

This option specifies the directory where the database cluster should be stored. This is the only information required by `initdb`, but you can avoid writing it by setting the `PGDATA` environment variable, which can be convenient since the database server (`postgres`) can find the database directory later by the same variable.

`-E encoding`

`--encoding=encoding`

Selects the encoding of the template database. This will also be the default encoding of any database you create later, unless you override it there. The default is derived from the locale, or `SQL_ASCII` if that does not work. The character sets supported by the Postgres Pro server are described in [Section 22.3.1](#).

`-g`

`--allow-group-access`

Allows users in the same group as the cluster owner to read all cluster files created by `initdb`. This option is ignored on Windows as it does not support POSIX-style group permissions.

`-k`

`--data-checksums`

Use checksums on data pages to help detect corruption by the I/O system that would otherwise be silent. Enabling checksums may incur a noticeable performance penalty. If set, checksums are calculated for all objects, in all databases. All checksum failures will be reported in the `pg_stat_database` view.

By default, Postgres Pro clusters are initialized with checksums enabled. To change this behavior, provide the `--no-data-checksums` option.

`--no-data-checksums`

Disable checksums on data pages.

By default, Postgres Pro clusters are initialized with checksums enabled.

`--locale=locale[@provider]`

Sets the default locale for the database cluster. If this option is not specified, the locale is inherited from the environment that `initdb` runs in. Locale support is described in [Section 22.1](#).

Optionally, you can specify the provider of the default collation after the `@` symbol. Supported values are `icu` and `libc`. For details, see [Section 22.2.2](#).

`--lc-collate=locale[@provider]`

`--lc-ctype=locale`

`--lc-messages=locale`

`--lc-monetary=locale`

`--lc-numeric=locale`

`--lc-time=locale`

Like `--locale`, but only sets the locale in the specified category.

`--no-locale`

Equivalent to `--locale=C`.

`-N`

`--no-sync`

By default, `initdb` will wait for all files to be written safely to disk. This option causes `initdb` to return without waiting, which is faster, but means that a subsequent operating system crash can leave the data directory corrupt. Generally, this option is useful for testing, but should not be used when creating a production installation.

`--pwfile=filename`

Makes `initdb` read the database superuser's password from a file. The first line of the file is taken as the password.

`-S`

`--sync-only`

Safely write all database files to disk and exit. This does not perform any of the normal `initdb` operations.

`-T config`

`--text-search-config=config`

Sets the default text search configuration. See [default\\_text\\_search\\_config](#) for further information.

`-U username`

`--username=username`

Selects the user name of the database superuser. This defaults to the name of the effective user running `initdb`. It is really not important what the superuser's name is, but one might choose to keep the customary name `postgres`, even if the operating system user's name is different.

`-W`

`--pwprompt`

Makes `initdb` prompt for a password to give the database superuser. If you don't plan on using password authentication, this is not important. Otherwise you won't be able to use password authentication until you have a password set up.

`-X directory`

`--waldir=directory`

This option specifies the directory where the write-ahead log should be stored.

`--wal-segsize=size`

Set the *WAL segment size*, in megabytes. This is the size of each individual file in the WAL log. The default size is 16 megabytes. The value must be a power of 2 between 1 and 1024 (megabytes). This option can only be set during initialization, and cannot be changed later.

It may be useful to adjust this size to control the granularity of WAL log shipping or archiving. Also, in databases with a high volume of WAL, the sheer number of WAL files per directory can become a performance and management problem. Increasing the WAL file size will reduce the number of WAL files.

Other, less commonly used, options are also available:

`-d`

`--debug`

Print debugging output from the bootstrap backend and a few other messages of lesser interest for the general public. The bootstrap backend is the program `initdb` uses to create the catalog tables. This option generates a tremendous amount of extremely boring output.

`-L directory`

Specifies where `initdb` should find its input files to initialize the database cluster. This is normally not necessary. You will be told if you need to specify their location explicitly.

`-n`

`--no-clean`

By default, when `initdb` determines that an error prevented it from completely creating the database cluster, it removes any files it might have created before discovering that it cannot finish the job. This option inhibits tidying-up and is thus useful for debugging.

Other options:

`-V`

`--version`

Print the `initdb` version and exit.

`-?`

`--help`

Show help about `initdb` command line arguments, and exit.

## Environment

`PGDATA`

Specifies the directory where the database cluster is to be stored; can be overridden using the `-D` option.

`PG_COLOR`

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

`TZ`

Specifies the default time zone of the created database cluster. The value should be a full time zone name (see [Section 8.5.3](#)).

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by `libpq` (see [Section 31.14](#)).

## Notes

`initdb` can also be invoked via `pg_ctl initdb`.

---

# pg\_archivecleanup

pg\_archivecleanup — clean up Postgres Pro WAL archive files

## Synopsis

```
pg_archivecleanup [option...] archivelocation oldestkeptwalfile
```

## Description

pg\_archivecleanup is designed to be used as an `archive_cleanup_command` to clean up WAL file archives when running as a standby server (see [Section 25.2](#)). pg\_archivecleanup can also be used as a standalone program to clean WAL file archives.

To configure a standby server to use pg\_archivecleanup, put this into its `postgresql.conf` configuration file:

```
archive_cleanup_command = 'pg_archivecleanup archivelocation %r'
```

where *archivelocation* is the directory from which WAL segment files should be removed.

When used within `archive_cleanup_command`, all WAL files logically preceding the value of the `%r` argument will be removed from *archivelocation*. This minimizes the number of files that need to be retained, while preserving crash-restart capability. Use of this parameter is appropriate if the *archivelocation* is a transient staging area for this particular standby server, but *not* when the *archivelocation* is intended as a long-term WAL archive area, or when multiple standby servers are recovering from the same archive location.

When used as a standalone program all WAL files logically preceding the *oldestkeptwalfile* will be removed from *archivelocation*. In this mode, if you specify a `.partial` or `.backup` file name, then only the file prefix will be used as the *oldestkeptwalfile*. This treatment of `.backup` file name allows you to remove all WAL files archived prior to a specific base backup without error. For example, the following example will remove all files older than WAL file name `0000000100000003700000010`:

```
pg_archivecleanup -d archive 0000000100000003700000010.00000020.backup
```

```
pg_archivecleanup: keep WAL file "archive/0000000100000003700000010" and later
pg_archivecleanup: removing file "archive/000000010000000370000000F"
pg_archivecleanup: removing file "archive/000000010000000370000000E"
```

pg\_archivecleanup assumes that *archivelocation* is a directory readable and writable by the server-owning user.

## Options

pg\_archivecleanup accepts the following command-line arguments:

`-d`

Print lots of debug logging output on `stderr`.

`-n`

Print the names of the files that would have been removed on `stdout` (performs a dry run).

`-V`

`--version`

Print the pg\_archivecleanup version and exit.

`-x extension`

Provide an extension that will be stripped from all file names before deciding if they should be deleted. This is typically useful for cleaning up archives that have been compressed during storage, and therefore have had an extension added by the compression program. For example: `-x .gz`.

`-?`

`--help`

Show help about `pg_archivecleanup` command line arguments, and exit.

## Environment

The environment variable `PG_COLOR` specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

## Notes

`pg_archivecleanup` is designed to work with PostgreSQL 8.0 and later when used as a standalone utility, or with PostgreSQL 9.0 and later when used as an archive cleanup command.

`pg_archivecleanup` is written in C and has an easy-to-modify source code, with specifically designated sections to modify for your own needs

## Examples

On Linux or Unix systems, you might use:

```
archive_cleanup_command = 'pg_archivecleanup -d /mnt/standby/archive %r 2>>cleanup.log'
```

where the archive directory is physically located on the standby server, so that the `archive_command` is accessing it across NFS, but the files are local to the standby. This will:

- produce debugging output in `cleanup.log`
- remove no-longer-needed files from the archive directory

---

# pg\_checksums

pg\_checksums — enable, disable or check data checksums in a Postgres Pro database cluster

## Synopsis

```
pg_checksums [option...] [[ -D | --pgdata ]datadir]
```

## Description

pg\_checksums checks, enables or disables data checksums in a Postgres Pro cluster. The server must be shut down cleanly before running pg\_checksums. When verifying checksums, the exit status is zero if there are no checksum errors, and nonzero if at least one checksum failure is detected. When enabling or disabling checksums, the exit status is nonzero if the operation failed.

When verifying checksums, every file in the cluster is scanned. When enabling checksums, every file in the cluster is rewritten in-place. Disabling checksums only updates the file `pg_control`.

## Options

The following command-line options are available:

`-D directory`

`--pgdata=directory`

Specifies the directory where the database cluster is stored.

`-c`

`--check`

Checks checksums. This is the default mode if nothing else is specified.

`-d`

`--disable`

Disables checksums.

`-e`

`--enable`

Enables checksums.

`-f filenode`

`--filenode=filenode`

Only validate checksums in the relation with filenode *filenode*.

`-N`

`--no-sync`

By default, pg\_checksums will wait for all files to be written safely to disk. This option causes pg\_checksums to return without waiting, which is faster, but means that a subsequent operating system crash can leave the updated data directory corrupt. Generally, this option is useful for testing but should not be used on a production installation. This option has no effect when using `--check`.

`-P`

`--progress`

Enable progress reporting. Turning this on will deliver a progress report while checking or enabling checksums.

`-v`  
`--verbose`  
Enable verbose output. Lists all checked files.

`-V`  
`--version`  
Print the `pg_checksums` version and exit.

`-?`  
`--help`  
Show help about `pg_checksums` command line arguments, and exit.

## Environment

`PGDATA`

Specifies the directory where the database cluster is stored; can be overridden using the `-D` option.

`PG_COLOR`

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

## Notes

Enabling checksums in a large cluster can potentially take a long time. During this operation, the cluster or other programs that write to the data directory must not be started or else data loss may occur.

When using a replication setup with tools which perform direct copies of relation file blocks (for example [pg\\_rewind](#)), enabling or disabling checksums can lead to page corruptions in the shape of incorrect checksums if the operation is not done consistently across all nodes. When enabling or disabling checksums in a replication setup, it is thus recommended to stop all the clusters before switching them all consistently. Destroying all standbys, performing the operation on the primary and finally recreating the standbys from scratch is also safe.

If `pg_checksums` is aborted or killed while enabling or disabling checksums, the cluster's data checksum configuration remains unchanged, and `pg_checksums` can be re-run to perform the same operation.

---

# pg\_controldata

pg\_controldata — display control information of a Postgres Pro database cluster

## Synopsis

```
pg_controldata [option] [[ -D | --pgdata ]datadir]
```

## Description

pg\_controldata prints information initialized during `initdb`, such as the catalog version. It also shows information about write-ahead logging and checkpoint processing. This information is cluster-wide, and not specific to any one database.

This utility can only be run by the user who initialized the cluster because it requires read access to the data directory. You can specify the data directory on the command line, or use the environment variable `PGDATA`. This utility supports the options `-v` and `--version`, which print the `pg_controldata` version and exit. It also supports options `-?` and `--help`, which output the supported arguments.

### Note

It is recommended that you use [pgpro\\_controldata](#) instead since it can read control information of different versions of PostgreSQL or Postgres Pro database clusters, including newer versions.

## Environment

`PGDATA`

Default data directory location

`PG_COLOR`

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

## See Also

[pgpro\\_controldata](#)

---

## pg\_ctl

`pg_ctl` — initialize, start, stop, or control a Postgres Pro server

### Synopsis

```
pg_ctl init [db] [-D datadir] [-s] [-o initdb-options]
```

```
pg_ctl start [-D datadir] [-l filename] [-W] [-t seconds] [-s] [-o options] [-p path] [-c]
```

```
pg_ctl stop [-D datadir] [-m s[mart] | f[ast] | i[mmediate] ] [-W] [-t seconds] [-s]
```

```
pg_ctl restart [-D datadir] [-m s[mart] | f[ast] | i[mmediate] ] [-W] [-t seconds] [-s] [-o options] [-c]
```

```
pg_ctl reload [-D datadir] [-s]
```

```
pg_ctl status [-D datadir]
```

```
pg_ctl promote [-D datadir] [-W] [-t seconds] [-s]
```

```
pg_ctl logrotate [-D datadir] [-s]
```

```
pg_ctl kill signal_name process_id
```

On Microsoft Windows, also:

```
pg_ctl register [-D datadir] [-N servicename] [-U username] [-P password] [-S a[uto] | d[emand] ] [-e source] [-W] [-t seconds] [-s] [-o options]
```

```
pg_ctl unregister [-N servicename]
```

### Description

`pg_ctl` is a utility for initializing a Postgres Pro database cluster, starting, stopping, or restarting the Postgres Pro database server ([postgres](#)), or displaying the status of a running server. Although the server can be started manually, `pg_ctl` encapsulates tasks such as redirecting log output and properly detaching from the terminal and process group. It also provides convenient options for controlled shutdown.

The `init` or `initdb` mode creates a new Postgres Pro database cluster, that is, a collection of databases that will be managed by a single server instance. This mode invokes the `initdb` command. See [initdb](#) for details.

`start` mode launches a new server. The server is started in the background, and its standard input is attached to `/dev/null` (or `nul` on Windows). On Unix-like systems, by default, the server's standard output and standard error are sent to `pg_ctl`'s standard output (not standard error). The standard output of `pg_ctl` should then be redirected to a file or piped to another process such as a log rotating program like `rotatelogs`; otherwise `postgres` will write its output to the controlling terminal (from the background) and will not leave the shell's process group. On Windows, by default the server's standard output and standard error are sent to the terminal. These default behaviors can be changed by using `-l` to append the server's output to a log file. Use of either `-l` or output redirection is recommended.

`stop` mode shuts down the server that is running in the specified data directory. Three different shutdown methods can be selected with the `-m` option. “Smart” mode disallows new connections, then waits for all existing clients to disconnect and any online backup to finish. If the server is in hot standby, recovery and streaming replication will be terminated once all clients have disconnected. “Fast” mode (the default) does not wait for clients to disconnect and will terminate an online backup in progress. All active transactions are rolled back and clients are forcibly disconnected, then the server is shut down. “Immediate” mode will abort all server processes immediately, without a clean shutdown. This choice will lead to a crash-recovery cycle during the next server start.

`restart` mode effectively executes a stop followed by a start. This allows changing the `postgres` command-line options, or changing configuration-file options that cannot be changed without restarting the server. If relative paths were used on the command line during server start, `restart` might fail unless `pg_ctl` is executed in the same current directory as it was during server start.

`reload` mode simply sends the `postgres` server process a `SIGHUP` signal, causing it to reread its configuration files (`postgresql.conf`, `pg_hba.conf`, etc.). This allows changing configuration-file options that do not require a full server restart to take effect.

`status` mode checks whether a server is running in the specified data directory. If it is, the server's PID and the command line options that were used to invoke it are displayed. If the server is not running, `pg_ctl` returns an exit status of 3. If an accessible data directory is not specified, `pg_ctl` returns an exit status of 4.

`promote` mode commands the standby server that is running in the specified data directory to end standby mode and begin read-write operations.

`logrotate` mode rotates the server log file. For details on how to use this mode with external log rotation tools, see [Section 23.3](#).

`kill` mode sends a signal to a specified process. This is primarily valuable on Microsoft Windows which does not have a built-in kill command. Use `--help` to see a list of supported signal names.

`register` mode registers the Postgres Pro server as a system service on Microsoft Windows. The `-s` option allows selection of service start type, either "auto" (start service automatically on system startup) or "demand" (start service on demand).

`unregister` mode unregisters a system service on Microsoft Windows. This undoes the effects of the `register` command.

## Options

`-c`  
`--core-files`

Attempt to allow server crashes to produce core files, on platforms where this is possible, by lifting any soft resource limit placed on core files. This is useful in debugging or diagnosing problems by allowing a stack trace to be obtained from a failed server process.

`-D datadir`  
`--pgdata=datadir`

Specifies the file system location of the database configuration files. If this option is omitted, the environment variable `PGDATA` is used.

`-l filename`  
`--log=filename`

Append the server log output to `filename`. If the file does not exist, it is created. The `umask` is set to `077`, so access to the log file is disallowed to other users by default.

`-m mode`  
`--mode=mode`

Specifies the shutdown mode. `mode` can be `smart`, `fast`, or `immediate`, or the first letter of one of these three. If this option is omitted, `fast` is the default.

`-o options`  
`--options=options`

Specifies options to be passed directly to the `postgres` command. `-o` can be specified multiple times, with all the given options being passed through.

The *options* should usually be surrounded by single or double quotes to ensure that they are passed through as a group.

`-o initdb-options`  
`--options=initdb-options`

Specifies options to be passed directly to the `initdb` command. `-o` can be specified multiple times, with all the given options being passed through.

The *initdb-options* should usually be surrounded by single or double quotes to ensure that they are passed through as a group.

`-p path`

Specifies the location of the `postgres` executable. By default the `postgres` executable is taken from the same directory as `pg_ctl`, or failing that, the hard-wired installation directory. It is not necessary to use this option unless you are doing something unusual and get errors that the `postgres` executable was not found.

In `init` mode, this option analogously specifies the location of the `initdb` executable.

`-s`  
`--silent`

Print only errors, no informational messages.

`-t seconds`  
`--timeout=seconds`

Specifies the maximum number of seconds to wait when waiting for an operation to complete (see option `-w`). Defaults to the value of the `PGCTLTIMEOUT` environment variable or, if not set, to 60 seconds.

`-V`  
`--version`

Print the `pg_ctl` version and exit.

`-w`  
`--wait`

Wait for the operation to complete. This is supported for the modes `start`, `stop`, `restart`, `promote`, and `register`, and is the default for those modes.

When waiting, `pg_ctl` repeatedly checks the server's PID file, sleeping for a short amount of time between checks. Startup is considered complete when the PID file indicates that the server is ready to accept connections. Shutdown is considered complete when the server removes the PID file. `pg_ctl` returns an exit code based on the success of the startup or shutdown.

If the operation does not complete within the timeout (see option `-t`), then `pg_ctl` exits with a nonzero exit status. But note that the operation might continue in the background and eventually succeed.

`-W`  
`--no-wait`

Do not wait for the operation to complete. This is the opposite of the option `-w`.

If waiting is disabled, the requested action is triggered, but there is no feedback about its success. In that case, the server log file or an external monitoring system would have to be used to check the progress and success of the operation.

In prior releases of Postgres Pro, this was the default except for the `stop` mode.

-?  
--help

Show help about pg\_ctl command line arguments, and exit.

If an option is specified that is valid, but not relevant to the selected operating mode, pg\_ctl ignores it.

## Options for Windows

-e *source*

Name of the event source for pg\_ctl to use for logging to the event log when running as a Windows service. The default is `Postgres Pro`. Note that this only controls messages sent from pg\_ctl itself; once started, the server will use the event source specified by its `event_source` parameter. Should the server fail very early in startup, before that parameter has been set, it might also log using the default event source name `Postgres Pro`.

-N *servicename*

Name of the system service to register. This name will be used as both the service name and the display name. The default is `Postgres Pro`.

-P *password*

Password for the user to run the service as.

-S *start-type*

Start type of the system service. *start-type* can be `auto`, or `demand`, or the first letter of one of these two. If this option is omitted, `auto` is the default.

-U *username*

User name for the user to run the service as. For domain users, use the format `DOMAIN\username`.

## Environment

PGCTLTIMEOUT

Default limit on the number of seconds to wait when waiting for startup or shutdown to complete. If not set, the default is 60 seconds.

PGDATA

Default data directory location.

Most pg\_ctl modes require knowing the data directory location; therefore, the `-D` option is required unless PGDATA is set.

pg\_ctl, like most other Postgres Pro utilities, also uses the environment variables supported by libpq (see [Section 31.14](#)).

For additional variables that affect the server, see [postgres](#).

## Files

postmaster.pid

pg\_ctl examines this file in the data directory to determine whether the server is currently running.

postmaster.opts

If this file exists in the data directory, pg\_ctl (in `restart` mode) will pass the contents of the file as options to postgres, unless overridden by the `-o` option. The contents of this file are also displayed in `status` mode.

## Examples

### Starting the Server

To start the server, waiting until the server is accepting connections:

```
$ pg_ctl start
```

To start the server using port 5433, and running without `fsync`, use:

```
$ pg_ctl -o "-F -p 5433" start
```

### Stopping the Server

To stop the server, use:

```
$ pg_ctl stop
```

The `-m` option allows control over *how* the server shuts down:

```
$ pg_ctl stop -m smart
```

### Restarting the Server

Restarting the server is almost equivalent to stopping the server and starting it again, except that by default, `pg_ctl` saves and reuses the command line options that were passed to the previously-running instance. To restart the server using the same options as before, use:

```
$ pg_ctl restart
```

But if `-o` is specified, that replaces any previous options. To restart using port 5433, disabling `fsync` upon restart:

```
$ pg_ctl -o "-F -p 5433" restart
```

### Showing the Server Status

Here is sample status output from `pg_ctl`:

```
$ pg_ctl status
```

```
pg_ctl: server is running (PID: 13718)
/usr/local/pgsql/bin/postgres "-D" "/usr/local/pgsql/data" "-p" "5433" "-B" "128"
```

The second line is the command that would be invoked in restart mode.

# pg\_resetwal

`pg_resetwal` — reset the write-ahead log and other control information of a Postgres Pro database cluster

## Synopsis

```
pg_resetwal [ -f | --force ] [ -n | --dry-run ] [option...] [ -D | --pgdata ] datadir
```

## Description

`pg_resetwal` clears the write-ahead log (WAL) and optionally resets some other control information stored in the `pg_control` file. This function is sometimes needed if these files have become corrupted. It should be used only as a last resort, when the server will not start due to such corruption.

After running this command, it should be possible to start the server, but bear in mind that the database might contain inconsistent data due to partially-committed transactions. You should immediately dump your data, run `initdb`, and reload. After reload, check for inconsistencies and repair as needed.

This utility can only be run by the user who installed the server, because it requires read/write access to the data directory. For safety reasons, you must specify the data directory on the command line. `pg_resetwal` does not use the environment variable `PGDATA`.

If `pg_resetwal` complains that it cannot determine valid data for `pg_control`, you can force it to proceed anyway by specifying the `-f` (force) option. In this case plausible values will be substituted for the missing data. Most of the fields can be expected to match, but manual assistance might be needed for the next OID, next transaction ID and epoch, next multitransaction ID and offset, and WAL starting location fields. These fields can be set using the options discussed below. If you are not able to determine correct values for all these fields, `-f` can still be used, but the recovered database must be treated with even more suspicion than usual: an immediate dump and reload is imperative. *Do not* execute any data-modifying operations in the database before you dump, as any such action is likely to make the corruption worse.

## Options

`-f`  
`--force`

Force `pg_resetwal` to proceed even if it cannot determine valid data for `pg_control`, as explained above.

`-n`  
`--dry-run`

The `-n/--dry-run` option instructs `pg_resetwal` to print the values reconstructed from `pg_control` and values about to be changed, and then exit without modifying anything. This is mainly a debugging tool, but can be useful as a sanity check before allowing `pg_resetwal` to proceed for real.

`-V`  
`--version`

Display version information, then exit.

`-?`  
`--help`

Show help, then exit.

The following options are only needed when `pg_resetwal` is unable to determine appropriate values by reading `pg_control`. Safe values can be determined as described below. For values that take numeric arguments, hexadecimal values can be specified by using the prefix `0x`.

```
-c xid,xid
--commit-timestamp-ids=xid,xid
```

Manually set the oldest and newest transaction IDs for which the commit time can be retrieved.

A safe value for the oldest transaction ID for which the commit time can be retrieved (first part) can be determined by looking for the numerically smallest file name in the directory `pg_commit_ts` under the data directory. Conversely, a safe value for the newest transaction ID for which the commit time can be retrieved (second part) can be determined by looking for the numerically greatest file name in the same directory. The file names are in hexadecimal.

```
-e xid_epoch
--epoch=xid_epoch
```

Manually set the next transaction ID's epoch.

The transaction ID epoch is not actually stored anywhere in the database except in the field that is set by `pg_resetwal`, so any value will work so far as the database itself is concerned. You might need to adjust this value to ensure that replication systems such as Slony-I and Skytools work correctly — if so, an appropriate value should be obtainable from the state of the downstream replicated database.

```
-l walfile
--next-wal-file=walfile
```

Manually set the WAL starting location by specifying the name of the next WAL segment file.

The name of next WAL segment file should be larger than any WAL segment file name currently existing in the directory `pg_wal` under the data directory. These names are also in hexadecimal and have three parts. The first part is the “timeline ID” and should usually be kept the same. For example, if `00000001000000320000004A` is the largest entry in `pg_wal`, use `-l 00000001000000320000004B` or higher.

Note that when using nondefault WAL segment sizes, the numbers in the WAL file names are different from the LSNs that are reported by system functions and system views. This option takes a WAL file name, not an LSN.

### Note

`pg_resetwal` itself looks at the files in `pg_wal` and chooses a default `-l` setting beyond the last existing file name. Therefore, manual adjustment of `-l` should only be needed if you are aware of WAL segment files that are not currently present in `pg_wal`, such as entries in an offline archive; or if the contents of `pg_wal` have been lost entirely.

```
-m mxid,mxid
--multixact-ids=mxid,mxid
```

Manually set the next and oldest multitransaction ID.

A safe value for the next multitransaction ID (first part) can be determined by looking for the numerically largest file name in the directory `pg_multixact/offsets` under the data directory, adding one, and then multiplying by 65536 (0x10000). Conversely, a safe value for the oldest multitransaction ID (second part of `-m`) can be determined by looking for the numerically smallest file name in the same directory and multiplying by 65536. The file names are in hexadecimal, so the easiest way to do this is to specify the option value in hexadecimal and append four zeroes.

```
-o oid
--next-oid=oid
```

Manually set the next OID.

There is no comparably easy way to determine a next OID that's beyond the largest one in the database, but fortunately it is not critical to get the next-OID setting right.

```
-O mxoff
--multixact-offset=mxoff
```

Manually set the next multitransaction offset.

A safe value can be determined by looking for the numerically largest file name in the directory `pg_multixact/members` under the data directory, adding one, and then multiplying by 52352 (0xCC80). The file names are in hexadecimal. There is no simple recipe such as the ones for other options of appending zeroes.

```
--wal-segsize=wal_segment_size
```

Set the new WAL segment size, in megabytes. The value must be set to a power of 2 between 1 and 1024 (megabytes). See the same option of [initdb](#) for more information.

### Note

While `pg_resetwal` will set the WAL starting address beyond the latest existing WAL segment file, some segment size changes can cause previous WAL file names to be reused. It is recommended to use `-l` together with this option to manually set the WAL starting address if WAL file name overlap will cause problems with your archiving strategy.

```
-u xid
--oldest-transaction-id=xid
```

Manually set the oldest unfrozen transaction ID.

A safe value can be determined by looking for the numerically smallest file name in the directory `pg_xact` under the data directory and then multiplying by 1048576 (0x100000). Note that the file names are in hexadecimal. It is usually easiest to specify the option value in hexadecimal too. For example, if `0007` is the smallest entry in `pg_xact`, `-u 0x700000` will work (five trailing zeroes provide the proper multiplier).

```
-x xid
--next-transaction-id=xid
```

Manually set the next transaction ID.

A safe value can be determined by looking for the numerically largest file name in the directory `pg_xact` under the data directory, adding one, and then multiplying by 1048576 (0x100000). Note that the file names are in hexadecimal. It is usually easiest to specify the option value in hexadecimal too. For example, if `0011` is the largest entry in `pg_xact`, `-x 0x1200000` will work (five trailing zeroes provide the proper multiplier).

## Environment

`PG_COLOR`

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

## Notes

This command must not be used when the server is running. `pg_resetwal` will refuse to start up if it finds a server lock file in the data directory. If the server crashed then a lock file might have been left behind; in that case you can remove the lock file to allow `pg_resetwal` to run. But before you do so, make doubly certain that there is no server process still alive.

`pg_resetwal` works only with servers of the same major version.

## pg\_rewind

`pg_rewind` — synchronize a Postgres Pro data directory with another data directory that was forked from it

### Synopsis

```
pg_rewind[option...]{-D|--target-pgdata} directory{--source-pgdata=directory|--source-server=connstr}
```

### Description

`pg_rewind` is a tool for synchronizing a Postgres Pro cluster with another copy of the same cluster, after the clusters' timelines have diverged. A typical scenario is to bring an old master server back online after failover as a standby that follows the new master.

After a successful rewind, the state of the target data directory is analogous to a base backup of the source data directory. Unlike taking a new base backup or using a tool like `rsync`, `pg_rewind` does not require comparing or copying unchanged relation blocks in the cluster. Only changed blocks from existing relation files are copied; all other files, including new relation files, configuration files, and WAL segments, are copied in full. As such the rewind operation is significantly faster than other approaches when the database is large and only a small fraction of blocks differ between the clusters.

`pg_rewind` examines the timeline histories of the source and target clusters to determine the point where they diverged, and expects to find WAL in the target cluster's `pg_wal` directory reaching all the way back to the point of divergence. The point of divergence can be found either on the target timeline, the source timeline, or their common ancestor. In the typical failover scenario where the target cluster was shut down soon after the divergence, this is not a problem, but if the target cluster ran for a long time after the divergence, its old WAL files might no longer be present. In this case, you can manually copy them from the WAL archive to the `pg_wal` directory, or run `pg_rewind` with the `-c` option to automatically retrieve them from the WAL archive. The use of `pg_rewind` is not limited to failover, e.g., a standby server can be promoted, run some write transactions, and then rewound to become a standby again.

After running `pg_rewind`, WAL replay needs to complete for the data directory to be in a consistent state. When the target server is started again it will enter archive recovery and replay all WAL generated in the source server from the last checkpoint before the point of divergence. If some of the WAL was no longer available in the source server when `pg_rewind` was run, and therefore could not be copied by the `pg_rewind` session, it must be made available when the target server is started. This can be done by creating a `recovery.signal` file in the target data directory and by configuring a suitable [restore\\_command](#) in `postgresql.conf`.

`pg_rewind` requires that the target server either has the [wal\\_log\\_hints](#) option enabled in `postgresql.conf` or data checksums enabled when the cluster was initialized with `initdb`. Neither of these are currently on by default. [full\\_page\\_writes](#) must also be set to `on`, but is enabled by default.

### Warning

If `pg_rewind` fails while processing, then the data folder of the target is likely not in a state that can be recovered. In such a case, taking a new fresh backup is recommended.

As `pg_rewind` copies configuration files entirely from the source, it may be required to correct the configuration used for recovery before restarting the target server, especially if the target is reintroduced as a standby of the source. If you restart the server after the rewind operation has finished but without configuring recovery, the target may again diverge from the primary.

`pg_rewind` will fail immediately if it finds files it cannot write directly to. This can happen for example when the source and the target server use the same file mapping for read-only SSL keys

and certificates. If such files are present on the target server it is recommended to remove them before running `pg_rewind`. After doing the rewind, some of those files may have been copied from the source, in which case it may be necessary to remove the data copied and restore back the set of links used before the rewind.

## Options

`pg_rewind` accepts the following command-line arguments:

`-D directory`

`--target-pgdata=directory`

This option specifies the target data directory that is synchronized with the source. The target server must be shut down cleanly before running `pg_rewind`

`--source-pgdata=directory`

Specifies the file system path to the data directory of the source server to synchronize the target with. This option requires the source server to be cleanly shut down.

`--source-server=connstr`

Specifies a `libpq` connection string to connect to the source Postgres Pro server to synchronize the target with. The connection must be a normal (non-replication) connection with a role having sufficient permissions to execute the functions used by `pg_rewind` on the source server (see Notes section for details) or a superuser role. This option requires the source server to be running and not in recovery mode.

`-R`

`--write-recovery-conf`

Create `standby.signal` and append connection settings to `postgresql.auto.conf` in the output directory. `--source-server` is mandatory with this option.

`-n`

`--dry-run`

Do everything except actually modifying the target directory.

`-N`

`--no-sync`

By default, `pg_rewind` will wait for all files to be written safely to disk. This option causes `pg_rewind` to return without waiting, which is faster, but means that a subsequent operating system crash can leave the data directory corrupt. Generally, this option is useful for testing but should not be used on a production installation.

`-P`

`--progress`

Enables progress reporting. Turning this on will deliver an approximate progress report while copying data from the source cluster.

`-c`

`--restore-target-wal`

Use `restore_command` defined in the target cluster configuration to retrieve WAL files from the WAL archive if these files are no longer available in the `pg_wal` directory.

`--debug`

Print verbose debugging output that is mostly useful for developers debugging `pg_rewind`.

`--no-ensure-shutdown`

`pg_rewind` requires that the target server is cleanly shut down before rewinding. By default, if the target server is not shut down cleanly, `pg_rewind` starts the target server in single-user mode to complete crash recovery first, and stops it. By passing this option, `pg_rewind` skips this and errors out immediately if the server is not cleanly shut down. Users are expected to handle the situation themselves in that case.

`-V`

`--version`

Display version information, then exit.

`-?`

`--help`

Show help, then exit.

## Environment

When `--source-server` option is used, `pg_rewind` also uses the environment variables supported by `libpq` (see [Section 31.14](#)).

The environment variable `PG_COLOR` specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

## Notes

When executing `pg_rewind` using an online cluster as source, a role having sufficient permissions to execute the functions used by `pg_rewind` on the source cluster can be used instead of a superuser. Here is how to create such a role, named `rewind_user` here:

```
CREATE USER rewind_user LOGIN;
GRANT EXECUTE ON function pg_catalog.pg_ls_dir(text, boolean, boolean) TO rewind_user;
GRANT EXECUTE ON function pg_catalog.pg_stat_file(text, boolean) TO rewind_user;
GRANT EXECUTE ON function pg_catalog.pg_read_binary_file(text) TO rewind_user;
GRANT EXECUTE ON function pg_catalog.pg_read_binary_file(text, bigint, bigint, boolean)
  TO rewind_user;
```

When executing `pg_rewind` using an online cluster as source which has been recently promoted, it is necessary to execute a `CHECKPOINT` after promotion such that its control file reflects up-to-date timeline information, which is used by `pg_rewind` to check if the target cluster can be rewound using the designated source cluster.

## How It Works

The basic idea is to copy all file system-level changes from the source cluster to the target cluster:

1. Scan the WAL log of the target cluster, starting from the last checkpoint before the point where the source cluster's timeline history forked off from the target cluster. For each WAL record, record each data block that was touched. This yields a list of all the data blocks that were changed in the target cluster, after the source cluster forked off. If some of the WAL files are no longer available, try re-running `pg_rewind` with the `-c` option to search for the missing files in the WAL archive.
2. Copy all those changed blocks from the source cluster to the target cluster, either using direct file system access (`--source-pgdata`) or SQL (`--source-server`). Relation files are now in a state equivalent to the moment of the last completed checkpoint prior to the point at which the WAL timelines of the source and target diverged plus the current state on the source of any blocks changed on the target after that divergence.
3. Copy all other files, including new relation files, WAL segments, `pg_xact`, and configuration files from the source cluster to the target cluster. Similarly to base backups, the contents of the directories `pg_dynshmem/`, `pg_notify/`, `pg_replslot/`, `pg_serial/`, `pg_snapshots/`, `pg_stat_tmp/`,

and `pg_subtrans/` are omitted from the data copied from the source cluster. The files `backup_label`, `tablespace_map`, `pg_internal.init`, `postmaster.opts`, and `postmaster.pid`, as well as any file or directory beginning with `pgsql_tmp`, are omitted.

4. Create a `backup_label` file to begin WAL replay at the checkpoint created at failover and configure the `pg_control` file with a minimum consistency LSN defined as the result of `pg_current_wal_insert_lsn()` when rewinding from a live source or the last checkpoint LSN when rewinding from a stopped source.
5. When starting the target, Postgres Pro Standard replays all the required WAL, resulting in a data directory in a consistent state.

---

## pg-setup

pg-setup — set up a new Postgres Pro database cluster and manage the corresponding service

### Synopsis

```
pg-setup initdb [initdb_options]
```

```
pg-setup find-free-port
```

```
pg-setup set-server-port port
```

```
pg-setup set parameter value
```

```
pg-setup service service_option
```

```
pg-setup tune conf
```

### Description

pg-setup is a shell script provided in the Postgres Pro distribution to automate database cluster setup on Linux systems. This script is provided as part of the `postgrespro-std-13-server` package. Once Postgres Pro is installed, you can find `pg-setup` in the `install-dir/bin` directory, where `install-dir` is `/opt/pgpro/std-13`.

pg-setup must be run as root, but performs database administration operations as user `postgres`. You can run this script with different options to:

- initialize the database cluster
- check for available ports and change the port used by Postgres Pro server
- change server configuration parameters
- enable/disable automatic startup of Postgres Pro service
- start, stop, or restart Postgres Pro service
- configure the database cluster for a specific Postgres Pro product

### Options

pg-setup accepts the following command-line arguments:

```
initdb [initdb_options]
```

Initialize the database cluster on behalf of the `postgres` user.

By default, the database cluster, configured for your Postgres Pro distribution, is initialized in the `/var/lib/pgpro/std-13/data` directory, with checksums enabled, `auth-local` parameter set to `peer`, and `auth-host` parameter set to `md5`. Localization settings are inherited from the `LANG` environment variable for the current session. All the `LC_*` environment variables are ignored. Optionally, you can provide `initdb` options to customize the installation.

If the default database is created using `pg-setup`, the path to its data directory is stored in the `/etc/default/postgrespro-standard-13` file, so all the subsequent `pg-setup` commands, as well as any commands that manage Postgres Pro service, affect this database only. You cannot manage several databases using `pg-setup`.

```
find-free-port
```

Search for a free port on your system. This option is useful if you are going to install more than one server instance, or the default 5432 port is used by another program.

`set-server-port port`

Specify the port number on which the server will listen for connections. Use this option to avoid conflicts if you are installing more than one server instance on the same system.

Default: 5432

`set name value`

Set the specified configuration parameter to the provided *value* in the `postgresql.conf` file. If this parameter has been already defined by the `ALTER SYSTEM` command, its previous value is removed from the `postgresql.auto.conf` file.

`service service_option`

Manage Postgres Pro service using one of the following options:

- `enable` — enable automatic service startup upon system restart.
- `disable` — disable automatic service startup upon system restart.
- `start` — start the service.
- `stop` — stop the service.
- `condrestart` — restart the service if it is running when `pg-setup` is invoked.
- `status` — return the Postgres Pro service status.

`tune conf`

Set the specified configuration for the database cluster. Predefined values of *conf* depend on the Postgres Pro edition and can be `1c`, `std` or `ent`. The value of `1c` can be specified for any product. By default, the database cluster is configured for your Postgres Pro Standard edition. If you provide a value different from any predefined, the cluster will get non-customized configuration settings.

For systems where more than one database server and/or application will run, you may need to adjust the configuration since `pg_setup` chooses the configuration settings depending on hardware characteristics, assuming that the system will use only one database server.

## Notes

If you are installing Postgres Pro from the `postgrespro-std-13` package, `pg-setup` is invoked automatically with the default settings. As a result, the database cluster is initialized and the default database is created in the `/var/lib/pgpro/std-13/data` directory, Postgres Pro service autostart is enabled, and the service is started.

If you are installing Postgres Pro server directly from the `postgrespro-std-13-server` package, you can run this script manually to initialize the database cluster or manage the Postgres Pro service.

For details on binary installation specifics on Linux, see [Section 16.1](#).

---

## pg\_test\_fsync

`pg_test_fsync` — determine fastest `wal_sync_method` for Postgres Pro

### Synopsis

```
pg_test_fsync [option...]
```

### Description

`pg_test_fsync` is intended to give you a reasonable idea of what the fastest [wal\\_sync\\_method](#) is on your specific system, as well as supplying diagnostic information in the event of an identified I/O problem. However, differences shown by `pg_test_fsync` might not make any significant difference in real database throughput, especially since many database servers are not speed-limited by their write-ahead logs. `pg_test_fsync` reports average file sync operation time in microseconds for each `wal_sync_method`, which can also be used to inform efforts to optimize the value of [commit\\_delay](#).

### Options

`pg_test_fsync` accepts the following command-line options:

- `-f`  
`--filename`  
Specifies the file name to write test data in. This file should be in the same file system that the `pg_wal` directory is or will be placed in. (`pg_wal` contains the WAL files.) The default is `pg_test_fsync.out` in the current directory.
- `-s`  
`--secs-per-test`  
Specifies the number of seconds for each test. The more time per test, the greater the test's accuracy, but the longer it takes to run. The default is 5 seconds, which allows the program to complete in under 2 minutes.
- `-V`  
`--version`  
Print the `pg_test_fsync` version and exit.
- `-?`  
`--help`  
Show help about `pg_test_fsync` command line arguments, and exit.

### Environment

The environment variable `PG_COLOR` specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

### See Also

[postgres](#)

---

# pg\_test\_timing

pg\_test\_timing — measure timing overhead

## Synopsis

pg\_test\_timing [*option...*]

## Description

pg\_test\_timing is a tool to measure the timing overhead on your system and confirm that the system time never moves backwards. Systems that are slow to collect timing data can give less accurate EXPLAIN ANALYZE results.

## Options

pg\_test\_timing accepts the following command-line options:

-d *duration*

--duration=*duration*

Specifies the test duration, in seconds. Longer durations give slightly better accuracy, and are more likely to discover problems with the system clock moving backwards. The default test duration is 3 seconds.

-V

--version

Print the pg\_test\_timing version and exit.

-?

--help

Show help about pg\_test\_timing command line arguments, and exit.

## Usage

### Interpreting Results

Good results will show most (>90%) individual timing calls take less than one microsecond. Average per loop overhead will be even lower, below 100 nanoseconds. This example from an Intel i7-860 system using a TSC clock source shows excellent performance:

Testing timing overhead for 3 seconds.

Per loop time including overhead: 35.96 ns

Histogram of timing durations:

< us	% of total	count
1	96.40465	80435604
2	3.59518	2999652
4	0.00015	126
8	0.00002	13
16	0.00000	2

Note that different units are used for the per loop time than the histogram. The loop can have resolution within a few nanoseconds (ns), while the individual timing calls can only resolve down to one microsecond (us).

### Measuring Executor Timing Overhead

When the query executor is running a statement using EXPLAIN ANALYZE, individual operations are timed as well as showing a summary. The overhead of your system can be checked by counting rows with the psql program:

```
CREATE TABLE t AS SELECT * FROM generate_series(1,100000);
\timing
SELECT COUNT(*) FROM t;
EXPLAIN ANALYZE SELECT COUNT(*) FROM t;
```

The i7-860 system measured runs the count query in 9.8 ms while the `EXPLAIN ANALYZE` version takes 16.6 ms, each processing just over 100,000 rows. That 6.8 ms difference means the timing overhead per row is 68 ns, about twice what `pg_test_timing` estimated it would be. Even that relatively small amount of overhead is making the fully timed count statement take almost 70% longer. On more substantial queries, the timing overhead would be less problematic.

## Changing Time Sources

On some newer Linux systems, it's possible to change the clock source used to collect timing data at any time. A second example shows the slowdown possible from switching to the slower `acpi_pm` time source, on the same system used for the fast results above:

```
# cat /sys/devices/system/clocksource/clocksource0/available_clocksource
tsc hpet acpi_pm
# echo acpi_pm > /sys/devices/system/clocksource/clocksource0/current_clocksource
# pg_test_timing
Per loop time including overhead: 722.92 ns
Histogram of timing durations:
  < us    % of total    count
    1     27.84870    1155682
    2     72.05956    2990371
    4      0.07810     3241
    8      0.01357      563
   16      0.00007       3
```

In this configuration, the sample `EXPLAIN ANALYZE` above takes 115.9 ms. That's 1061 ns of timing overhead, again a small multiple of what's measured directly by this utility. That much timing overhead means the actual query itself is only taking a tiny fraction of the accounted for time, most of it is being consumed in overhead instead. In this configuration, any `EXPLAIN ANALYZE` totals involving many timed operations would be inflated significantly by timing overhead.

FreeBSD also allows changing the time source on the fly, and it logs information about the timer selected during boot:

```
# dmesg | grep "Timecounter"
Timecounter "ACPI-fast" frequency 3579545 Hz quality 900
Timecounter "i8254" frequency 1193182 Hz quality 0
Timecounters tick every 10.000 msec
Timecounter "TSC" frequency 2531787134 Hz quality 800
# sysctl kern.timecounter.hardware=TSC
kern.timecounter.hardware: ACPI-fast -> TSC
```

Other systems may only allow setting the time source on boot. On older Linux systems the "clock" kernel setting is the only way to make this sort of change. And even on some more recent ones, the only option you'll see for a clock source is "jiffies". Jiffies are the older Linux software clock implementation, which can have good resolution when it's backed by fast enough timing hardware, as in this example:

```
$ cat /sys/devices/system/clocksource/clocksource0/available_clocksource
jiffies
$ dmesg | grep time.c
time.c: Using 3.579545 MHz WALL PM GTOD PIT/TSC timer.
time.c: Detected 2400.153 MHz processor.
$ pg_test_timing
Testing timing overhead for 3 seconds.
Per timing duration including loop overhead: 97.75 ns
Histogram of timing durations:
```

< us	% of total	count
1	90.23734	27694571
2	9.75277	2993204
4	0.00981	3010
8	0.00007	22
16	0.00000	1
32	0.00000	1

## Clock Hardware and Timing Accuracy

Collecting accurate timing information is normally done on computers using hardware clocks with various levels of accuracy. With some hardware the operating systems can pass the system clock time almost directly to programs. A system clock can also be derived from a chip that simply provides timing interrupts, periodic ticks at some known time interval. In either case, operating system kernels provide a clock source that hides these details. But the accuracy of that clock source and how quickly it can return results varies based on the underlying hardware.

Inaccurate time keeping can result in system instability. Test any change to the clock source very carefully. Operating system defaults are sometimes made to favor reliability over best accuracy. And if you are using a virtual machine, look into the recommended time sources compatible with it. Virtual hardware faces additional difficulties when emulating timers, and there are often per operating system settings suggested by vendors.

The Time Stamp Counter (TSC) clock source is the most accurate one available on current generation CPUs. It's the preferred way to track the system time when it's supported by the operating system and the TSC clock is reliable. There are several ways that TSC can fail to provide an accurate timing source, making it unreliable. Older systems can have a TSC clock that varies based on the CPU temperature, making it unusable for timing. Trying to use TSC on some older multicore CPUs can give a reported time that's inconsistent among multiple cores. This can result in the time going backwards, a problem this program checks for. And even the newest systems can fail to provide accurate TSC timing with very aggressive power saving configurations.

Newer operating systems may check for the known TSC problems and switch to a slower, more stable clock source when they are seen. If your system supports TSC time but doesn't default to that, it may be disabled for a good reason. And some operating systems may not detect all the possible problems correctly, or will allow using TSC even in situations where it's known to be inaccurate.

The High Precision Event Timer (HPET) is the preferred timer on systems where it's available and TSC is not accurate. The timer chip itself is programmable to allow up to 100 nanosecond resolution, but you may not see that much accuracy in your system clock.

Advanced Configuration and Power Interface (ACPI) provides a Power Management (PM) Timer, which Linux refers to as the `acpi_pm`. The clock derived from `acpi_pm` will at best provide 300 nanosecond resolution.

Timers used on older PC hardware include the 8254 Programmable Interval Timer (PIT), the real-time clock (RTC), the Advanced Programmable Interrupt Controller (APIC) timer, and the Cyclone timer. These timers aim for millisecond resolution.

# pg\_upgrade

pg\_upgrade — upgrade a Postgres Pro server instance

## Synopsis

```
pg_upgrade -b oldbindir [-B newbindir] -d oldconfigdir -D newconfigdir [option...]
```

## Description

pg\_upgrade (formerly called pg\_migrator) allows data stored in PostgreSQL or Postgres Pro data files to be upgraded to a later Postgres Pro major version without the data dump/reload typically required for major version upgrades, e.g., from 9.5.8 to 9.6.4 or from 10.7 to 11.2. It is not required for minor version upgrades, e.g., from 9.6.2 to 9.6.3 or from 10.1 to 10.2.

Major Postgres Pro releases regularly add new features that often change the layout of the system tables, but the internal data storage format rarely changes. pg\_upgrade uses this fact to perform rapid upgrades by creating new system tables and simply reusing the old user data files. If a future major release ever changes the data storage format in a way that makes the old data format unreadable, pg\_upgrade will not be usable for such upgrades. (The community will attempt to avoid such situations.)

pg\_upgrade does its best to make sure the old and new clusters are binary-compatible, e.g., by checking for compatible compile-time settings, including 32/64-bit binaries. It is important that any external modules are also binary compatible, though this cannot be checked by pg\_upgrade.

pg\_upgrade supports upgrades from 8.4.X and later to the current major release of Postgres Pro, including snapshot and beta releases.

## Options

pg\_upgrade accepts the following command-line arguments:

`-b bindir`

`--old-bindir=bindir`

the old Postgres Pro executable directory; environment variable `PGBINOLD`

`-B bindir`

`--new-bindir=bindir`

the new Postgres Pro executable directory; default is the directory where pg\_upgrade resides; environment variable `PGBINNEW`

`-c`

`--check`

check clusters only, don't change any data

`-d configdir`

`--old-datadir=configdir`

the old database cluster configuration directory; environment variable `PGDATAOLD`

`-D configdir`

`--new-datadir=configdir`

the new database cluster configuration directory; environment variable `PGDATANEW`

`-j njobs`

`--jobs=njobs`

number of simultaneous processes or threads to use

`-k`  
`--link`  
use hard links instead of copying files to the new cluster

`-o options`  
`--old-options options`  
options to be passed directly to the old `postgres` command; multiple option invocations are appended

`-O options`  
`--new-options options`  
options to be passed directly to the new `postgres` command; multiple option invocations are appended

`-p port`  
`--old-port=port`  
the old cluster port number; environment variable `PGPORTOLD`

`-P port`  
`--new-port=port`  
the new cluster port number; environment variable `PGPORTNEW`

`-r`  
`--retain`  
retain SQL and log files even after successful completion

`-s dir`  
`--socketdir=dir`  
directory to use for postmaster sockets during upgrade; default is current working directory; environment variable `PGSOCKETDIR`

`-U username`  
`--username=username`  
cluster's install user name; environment variable `PGUSER`

`-v`  
`--verbose`  
enable verbose internal logging

`-V`  
`--version`  
display version information, then exit

`--clone`  
Use efficient file cloning (also known as “relinks” on some systems) instead of copying files to the new cluster. This can result in near-instantaneous copying of the data files, giving the speed advantages of `-k/--link` while leaving the old cluster untouched.

File cloning is only supported on some operating systems and file systems. If it is selected but not supported, the `pg_upgrade` run will error. At present, it is supported on Linux (kernel 4.5 or later) with Btrfs and XFS (on file systems created with reflink support), and on macOS with APFS.

`-?`  
`--help`  
show help, then exit

## Usage

These are the steps to perform an upgrade with `pg_upgrade`:

### 1. Optionally move the old cluster

If you are using a version-specific installation directory, e.g., `/opt/PostgreSQL/13`, you do not need to move the old cluster. The graphical installers all use version-specific installation directories.

If your installation directory is not version-specific, e.g., `/usr/local/pgsql`, it is necessary to move the current Postgres Pro install directory so it does not interfere with the new Postgres Pro installation. Once the current Postgres Pro server is shut down, it is safe to rename the Postgres Pro installation directory; assuming the old directory is `/usr/local/pgsql`, you can do:

```
mv /usr/local/pgsql /usr/local/pgsql.old
```

to rename the directory.

### 2. Install the new Postgres Pro binaries

Install the new server's binaries and support files. `pg_upgrade` is included in a default installation.

### 3. Initialize the new Postgres Pro cluster

Initialize the new cluster using `initdb`. Use compatible `initdb` flags that match the old cluster. Many prebuilt installers do this step automatically. There is no need to start the new cluster.

### 4. Install extension shared object files

Many extensions and custom modules, whether from `contrib` or another source, use shared object files (or DLLs), e.g., `pgcrypto.so`. If the old cluster used these, shared object files matching the new server binary must be installed in the new cluster, usually via operating system commands. Do not load the schema definitions, e.g., `CREATE EXTENSION pgcrypto`, because these will be duplicated from the old cluster. If extension updates are available, `pg_upgrade` will report this and create a script that can be run later to update them.

### 5. Copy custom full-text search files

Copy any custom full text search files (dictionary, synonym, thesaurus, stop words) from the old to the new cluster.

### 6. Adjust authentication

`pg_upgrade` will connect to the old and new servers several times, so you might want to set authentication to `peer` in `pg_hba.conf` or use a `~/.pgpass` file (see [Section 31.15](#)).

### 7. Stop both servers

Make sure both database servers are stopped using, on Unix, e.g.:

```
pg_ctl -D /opt/PostgreSQL/9.6 stop
pg_ctl -D /opt/PostgreSQL/13 stop
```

or on Windows, using the proper service names:

```
NET STOP postgresql-9.6
NET STOP postgresql-13
```

Streaming replication and log-shipping standby servers can remain running until a later step.

### 8. Prepare for standby server upgrades

If you are upgrading standby servers using methods outlined in section [Step 10](#), verify that the old standby servers are caught up by running `pg_controldata` against the old primary and standby clusters. Verify that the “Latest checkpoint location” values match in all clusters. (There will be a mismatch if old standby servers were shut down before the old primary or if the old standby servers are still running.) Also, make sure `wal_level` is not set to `minimal` in the `postgresql.conf` file on the new primary cluster.

## 9. Run pg\_upgrade

Always run the `pg_upgrade` binary of the new server, not the old one. `pg_upgrade` requires the specification of the old and new cluster's data and executable (`bin`) directories. You can also specify user and port values, and whether you want the data files linked or cloned instead of the default copy behavior.

If you use link mode, the upgrade will be much faster (no file copying) and use less disk space, but you will not be able to access your old cluster once you start the new cluster after the upgrade. Link mode also requires that the old and new cluster data directories be in the same file system. (Tablespaces and `pg_wal` can be on different file systems.) Clone mode provides the same speed and disk space advantages but does not cause the old cluster to be unusable once the new cluster is started. Clone mode also requires that the old and new data directories be in the same file system. This mode is only available on certain operating systems and file systems.

The `--jobs` option allows multiple CPU cores to be used for copying/linking of files and to dump and reload database schemas in parallel; a good place to start is the maximum of the number of CPU cores and tablespaces. This option can dramatically reduce the time to upgrade a multi-database server running on a multiprocessor machine.

For Windows users, you must be logged into an administrative account, and then start a shell as the `postgres` user and set the proper path:

```
RUNAS /USER:postgres "CMD.EXE"  
SET PATH=%PATH%;C:\Program Files\PostgreSQL\13\bin;
```

and then run `pg_upgrade` with quoted directories, e.g.:

```
pg_upgrade.exe  
  --old-datadir "C:/Program Files/PostgreSQL/9.6/data"  
  --new-datadir "C:/Program Files/PostgreSQL/13/data"  
  --old-bindir "C:/Program Files/PostgreSQL/9.6/bin"  
  --new-bindir "C:/Program Files/PostgreSQL/13/bin"
```

Once started, `pg_upgrade` will verify the two clusters are compatible and then do the upgrade. You can use `pg_upgrade --check` to perform only the checks, even if the old server is still running. `pg_upgrade --check` will also outline any manual adjustments you will need to make after the upgrade. If you are going to be using link or clone mode, you should use the option `--link` or `--clone` with `--check` to enable mode-specific checks. `pg_upgrade` requires write permission in the current directory.

Obviously, no one should be accessing the clusters during the upgrade. `pg_upgrade` defaults to running servers on port 50432 to avoid unintended client connections. You can use the same port number for both clusters when doing an upgrade because the old and new clusters will not be running at the same time. However, when checking an old running server, the old and new port numbers must be different.

If an error occurs while restoring the database schema, `pg_upgrade` will exit and you will have to revert to the old cluster as outlined in [Step 16](#) below. To try `pg_upgrade` again, you will need to modify the old cluster so the `pg_upgrade` schema restore succeeds. If the problem is a `contrib` module, you might need to uninstall the `contrib` module from the old cluster and install it in the new cluster after the upgrade, assuming the module is not being used to store user data.

## 10. Upgrade streaming replication and log-shipping standby servers

If you used link mode and have Streaming Replication (see [Section 25.2.5](#)) or Log-Shipping (see [Section 25.2](#)) standby servers, you can follow these steps to quickly upgrade them. You will not be running `pg_upgrade` on the standby servers, but rather `rsync` on the primary. Do not start any servers yet.

If you did *not* use link mode, do not have or do not want to use rsync, or want an easier solution, skip the instructions in this section and simply recreate the standby servers once pg\_upgrade completes and the new primary is running.

a. **Install the new Postgres Pro binaries on standby servers**

Make sure the new binaries and support files are installed on all standby servers.

b. **Make sure the new standby data directories do *not* exist**

Make sure the new standby data directories do *not* exist or are empty. If initdb was run, delete the standby servers' new data directories.

c. **Install extension shared object files**

Install the same extension shared object files on the new standbys that you installed in the new primary cluster.

d. **Stop standby servers**

If the standby servers are still running, stop them now using the above instructions.

e. **Save configuration files**

Save any configuration files from the old standbys' configuration directories you need to keep, e.g., `postgresql.conf` (and any files included by it), `postgresql.auto.conf`, `pg_hba.conf`, because these will be overwritten or removed in the next step.

f. **Run rsync**

When using link mode, standby servers can be quickly upgraded using rsync. To accomplish this, from a directory on the primary server that is above the old and new database cluster directories, run this on the *primary* for each standby server:

```
rsync --archive --delete --hard-links --size-only --no-inc-recursive old_cluster
  new_cluster remote_dir
```

where `old_cluster` and `new_cluster` are relative to the current directory on the primary, and `remote_dir` is *above* the old and new cluster directories on the standby. The directory structure under the specified directories on the primary and standbys must match. Consult the rsync manual page for details on specifying the remote directory, e.g.,

```
rsync --archive --delete --hard-links --size-only --no-inc-recursive /opt/
PostgreSQL/9.5 \
  /opt/PostgreSQL/9.6 standby.example.com:/opt/PostgreSQL
```

You can verify what the command will do using rsync's `--dry-run` option. While rsync must be run on the primary for at least one standby, it is possible to run rsync on an upgraded standby to upgrade other standbys, as long as the upgraded standby has not been started.

What this does is to record the links created by pg\_upgrade's link mode that connect files in the old and new clusters on the primary server. It then finds matching files in the standby's old cluster and creates links for them in the standby's new cluster. Files that were not linked on the primary are copied from the primary to the standby. (They are usually small.) This provides rapid standby upgrades. Unfortunately, rsync needlessly copies files associated with temporary and unlogged tables because these files don't normally exist on standby servers.

If you have tablespaces, you will need to run a similar rsync command for each tablespace directory, e.g.:

```
rsync --archive --delete --hard-links --size-only --no-inc-recursive /vol1/
pg_tblsp/Pg_9.5_201510051 \
```

```
/vol1/pg_tblsp/PG_9.6_201608131 standby.example.com:/vol1/pg_tblsp
```

If you have relocated `pg_wal` outside the data directories, `rsync` must be run on those directories too.

#### g. **Configure streaming replication and log-shipping standby servers**

Configure the servers for log shipping. (You do not need to run `pg_start_backup()` and `pg_stop_backup()` or take a file system backup as the standbys are still synchronized with the primary.)

#### 11. **Restore `pg_hba.conf`**

If you modified `pg_hba.conf`, restore its original settings. It might also be necessary to adjust other configuration files in the new cluster to match the old cluster, e.g., `postgresql.conf` (and any files included by it), `postgresql.auto.conf`.

#### 12. **Start the new server**

The new server can now be safely started, and then any `rsync`'ed standby servers.

#### 13. **Post-upgrade processing**

If any post-upgrade processing is required, `pg_upgrade` will issue warnings as it completes. It will also generate script files that must be run by the administrator. The script files will connect to each database that needs post-upgrade processing. Each script should be run using:

```
psql --username=postgres --file=script.sql postgres
```

The scripts can be run in any order and can be deleted once they have been run.

### **Caution**

In general it is unsafe to access tables referenced in rebuild scripts until the rebuild scripts have run to completion; doing so could yield incorrect results or poor performance. Tables not referenced in rebuild scripts can be accessed immediately.

#### 14. **Statistics**

Because optimizer statistics are not transferred by `pg_upgrade`, you will be instructed to run a command to regenerate that information at the end of the upgrade. You might need to set connection parameters to match your new cluster.

#### 15. **Delete old cluster**

Once you are satisfied with the upgrade, you can delete the old cluster's data directories by running the script mentioned when `pg_upgrade` completes. (Automatic deletion is not possible if you have user-defined tablespaces inside the old data directory.) You can also delete the old installation directories (e.g., `bin`, `share`).

#### 16. **Reverting to old cluster**

If, after running `pg_upgrade`, you wish to revert to the old cluster, there are several options:

- If the `--check` option was used, the old cluster was unmodified; it can be restarted.
- If the `--link` option was *not* used, the old cluster was unmodified; it can be restarted.
- If the `--link` option was used, the data files might be shared between the old and new cluster:
  - If `pg_upgrade` aborted before linking started, the old cluster was unmodified; it can be restarted.
  - If you did *not* start the new cluster, the old cluster was unmodified except that, when linking started, a `.old` suffix was appended to `$PGDATA/global/pg_control`. To reuse the old cluster, remove the `.old` suffix from `$PGDATA/global/pg_control`; you can then restart the old cluster.

- If you did start the new cluster, it has written to shared files and it is unsafe to use the old cluster. The old cluster will need to be restored from backup in this case.

## Notes

`pg_upgrade` creates various working files, such as schema dumps, in the current working directory. For security, be sure that that directory is not readable or writable by any other users.

`pg_upgrade` launches short-lived postmasters in the old and new data directories. Temporary Unix socket files for communication with these postmasters are, by default, made in the current working directory. In some situations the path name for the current directory might be too long to be a valid socket name. In that case you can use the `-s` option to put the socket files in some directory with a shorter path name. For security, be sure that that directory is not readable or writable by any other users. (This is not supported on Windows.)

All failure, rebuild, and reindex cases will be reported by `pg_upgrade` if they affect your installation; post-upgrade scripts to rebuild tables and indexes will be generated automatically. If you are trying to automate the upgrade of many clusters, you should find that clusters with identical database schemas require the same post-upgrade steps for all cluster upgrades; this is because the post-upgrade steps are based on the database schemas, and not user data.

For deployment testing, create a schema-only copy of the old cluster, insert dummy data, and upgrade that.

`pg_upgrade` does not support upgrading of databases containing table columns using these `reg*` OID-referencing system data types:

```
regcollation
regconfig
regdictionary
regnamespace
regoper
regoperator
regproc
regprocedure
```

(`regclass`, `regrole`, and `regtype` can be upgraded.)

If you are upgrading a pre-PostgreSQL 9.2 cluster that uses a configuration-file-only directory, you must pass the real data directory location to `pg_upgrade`, and pass the configuration directory location to the server, e.g., `-d /real-data-directory -o '-D /configuration-directory'`.

If using a pre-9.1 old server that is using a non-default Unix-domain socket directory or a default that differs from the default of the new cluster, set `PGHOST` to point to the old server's socket location. (This is not relevant on Windows.)

When performing an upgrade from Postgres Pro 9.6 or lower, for databases with a multibyte encoding, `pg_upgrade` may generate SQL files with `REINDEX/VALIDATE` commands. You must run these files to rebuild indexes and re-validate constraints. This can happen in the following cases:

- The old cluster uses indexes or constraints depending on collations other than the default collation of the database, `C`, or `POSIX`.
- On Windows, the old cluster uses indexes or constraints depending on the default collation with a verbose name, such as `"Russian_Russia[.encoding]"` or `"English_United States[.encoding]"`.

If you want to use link mode and you do not want your old cluster to be modified when the new cluster is started, consider using the clone mode. If that is not available, make a copy of the old cluster and upgrade that in link mode. To make a valid copy of the old cluster, use `rsync` to create a dirty copy of the old cluster while the server is running, then shut down the old server and run `rsync --checksum` again to update the copy with any changes to make it consistent. (`--checksum` is necessary because `rsync`

only has file modification-time granularity of one second.) You might want to exclude some files, e.g., `postmaster.pid`, as documented in [Section 24.3.3](#). If your file system supports file system snapshots or copy-on-write file copies, you can use that to make a backup of the old cluster and tablespaces, though the snapshot and copies must be created simultaneously or while the database server is down.

# pg\_waldump

`pg_waldump` — display a human-readable rendering of the write-ahead log of a Postgres Pro database cluster

## Synopsis

```
pg_waldump [option...] [startseg [endseg]]
```

## Description

`pg_waldump` displays the write-ahead log (WAL) and is mainly useful for debugging or educational purposes.

This utility can only be run by the user who installed the server, because it requires read-only access to the data directory.

## Options

The following command-line options control the location and format of the output:

*startseg*

Start reading at the specified log segment file. This implicitly determines the path in which files will be searched for, and the timeline to use.

*endseg*

Stop after reading the specified log segment file.

`-b`

`--bkp-details`

Output detailed information about backup blocks.

`-e end`

`--end=end`

Stop reading at the specified WAL location, instead of reading to the end of the log stream.

`-f`

`--follow`

After reaching the end of valid WAL, keep polling once per second for new WAL to appear.

`-n limit`

`--limit=limit`

Display the specified number of records, then stop.

`-p path`

`--path=path`

Specifies a directory to search for log segment files or a directory with a `pg_wal` subdirectory that contains such files. The default is to search in the current directory, the `pg_wal` subdirectory of the current directory, and the `pg_wal` subdirectory of `PGDATA`.

`-q`

`--quiet`

Do not print any output, except for errors. This option can be useful when you want to know whether a range of WAL records can be successfully parsed but don't care about the record contents.

`-r rmgr`  
`--rmgr=rmgr`

Only display records generated by the specified resource manager. If `list` is passed as name, print a list of valid resource manager names, and exit.

`-s start`  
`--start=start`

WAL location at which to start reading. The default is to start reading the first valid log record found in the earliest file found.

`-t timeline`  
`--timeline=timeline`

Timeline from which to read log records. The default is to use the value in `startseg`, if that is specified; otherwise, the default is 1.

`-V`  
`--version`

Print the `pg_waldump` version and exit.

`-x xid`  
`--xid=xid`

Only display records marked with the given transaction ID.

`-z`  
`--stats[=record]`

Display summary statistics (number and size of records and full-page images) instead of individual records. Optionally generate statistics per-record instead of `per-rmgr`.

`-?`  
`--help`

Show help about `pg_waldump` command line arguments, and exit.

## Environment

`PGDATA`

Data directory; see also the `-p` option.

`PG_COLOR`

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

## Notes

Can give wrong results when the server is running.

Only the specified timeline is displayed (or the default, if none is specified). Records in other timelines are ignored.

`pg_waldump` cannot read WAL files with suffix `.partial`. If those files need to be read, `.partial` suffix needs to be removed from the file name.

# postgres

postgres — Postgres Pro database server

## Synopsis

```
postgres [option...]
```

## Description

`postgres` is the Postgres Pro database server. In order for a client application to access a database it connects (over a network or locally) to a running `postgres` instance. The `postgres` instance then starts a separate server process to handle the connection.

One `postgres` instance always manages the data of exactly one database cluster. A database cluster is a collection of databases that is stored at a common file system location (the “data area”). More than one `postgres` instance can run on a system at one time, so long as they use different data areas and different communication ports (see below). When `postgres` starts it needs to know the location of the data area. The location must be specified by the `-D` option or the `PGDATA` environment variable; there is no default. Typically, `-D` or `PGDATA` points directly to the data area directory created by `initdb`. Other possible file layouts are discussed in [Section 18.2](#).

By default `postgres` starts in the foreground and prints log messages to the standard error stream. In practical applications `postgres` should be started as a background process, perhaps at boot time.

The `postgres` command can also be called in single-user mode. The primary use for this mode is during bootstrapping by `initdb`. Sometimes it is used for debugging or disaster recovery; note that running a single-user server is not truly suitable for debugging the server, since no realistic interprocess communication and locking will happen. When invoked in single-user mode from the shell, the user can enter queries and the results will be printed to the screen, but in a form that is more useful for developers than end users. In the single-user mode, the session user will be set to the user with ID 1, and implicit superuser powers are granted to this user. This user does not actually have to exist, so the single-user mode can be used to manually recover from certain kinds of accidental damage to the system catalogs.

## Options

`postgres` accepts the following command-line arguments. For a detailed discussion of the options consult [Chapter 18](#). You can save typing most of these options by setting up a configuration file. Some (safe) options can also be set from the connecting client in an application-dependent way to apply only for that session. For example, if the environment variable `PGOPTIONS` is set, then libpq-based clients will pass that string to the server, which will interpret it as `postgres` command-line options.

## General Purpose

`-B nbuffers`

Sets the number of shared buffers for use by the server processes. The default value of this parameter is chosen automatically by `initdb`. Specifying this option is equivalent to setting the `shared_buffers` configuration parameter.

`-c name=value`

Sets a named run-time parameter. The configuration parameters supported by Postgres Pro are described in [Chapter 18](#). Most of the other command line options are in fact short forms of such a parameter assignment. `-c` can appear multiple times to set multiple parameters.

`-C name`

Prints the value of the named run-time parameter, and exits. (See the `-c` option above for details.) This can be used on a running server, and returns values from `postgresql.conf`, modified by any

parameters supplied in this invocation. It does not reflect parameters supplied when the cluster was started.

This option is meant for other programs that interact with a server instance, such as `pg_ctl`, to query configuration parameter values. User-facing applications should instead use `SHOW` or the `pg_settings` view.

`-d debug-level`

Sets the debug level. The higher this value is set, the more debugging output is written to the server log. Values are from 1 to 5. It is also possible to pass `-d 0` for a specific session, which will prevent the server log level of the parent `postgres` process from being propagated to this session.

`-D datadir`

Specifies the file system location of the database configuration files. See [Section 18.2](#) for details.

`-e`

Sets the default date style to “European”, that is `DMY` ordering of input date fields. This also causes the day to be printed before the month in certain date output formats. See [Section 8.5](#) for more information.

`-F`

Disables `fsync` calls for improved performance, at the risk of data corruption in the event of a system crash. Specifying this option is equivalent to disabling the `fsync` configuration parameter. Read the detailed documentation before using this!

`-h hostname`

Specifies the IP host name or address on which `postgres` is to listen for TCP/IP connections from client applications. The value can also be a comma-separated list of addresses, or `*` to specify listening on all available interfaces. An empty value specifies not listening on any IP addresses, in which case only Unix-domain sockets can be used to connect to the server. Defaults to listening only on localhost. Specifying this option is equivalent to setting the `listen_addresses` configuration parameter.

`-i`

Allows remote clients to connect via TCP/IP (Internet domain) connections. Without this option, only local connections are accepted. This option is equivalent to setting `listen_addresses` to `*` in `postgresql.conf` or via `-h`.

This option is deprecated since it does not allow access to the full functionality of `listen_addresses`. It's usually better to set `listen_addresses` directly.

`-k directory`

Specifies the directory of the Unix-domain socket on which `postgres` is to listen for connections from client applications. The value can also be a comma-separated list of directories. An empty value specifies not listening on any Unix-domain sockets, in which case only TCP/IP sockets can be used to connect to the server. The default value is normally `/tmp`, but that can be changed at build time. Specifying this option is equivalent to setting the `unix_socket_directories` configuration parameter.

`-l`

Enables secure connections using SSL. Postgres Pro must have been compiled with support for SSL for this option to be available. For more information on using SSL, refer to [Section 17.9](#).

`-N max-connections`

Sets the maximum number of client connections that this server will accept. The default value of this parameter is chosen automatically by `initdb`. Specifying this option is equivalent to setting the `max_connections` configuration parameter.

`-o extra-options`

The command-line-style arguments specified in *extra-options* are passed to all server processes started by this `postgres` process.

Spaces within *extra-options* are considered to separate arguments, unless escaped with a backslash (`\`); write `\\` to represent a literal backslash. Multiple arguments can also be specified via multiple uses of `-o`.

The use of this option is obsolete; all command-line options for server processes can be specified directly on the `postgres` command line.

`-p port`

Specifies the TCP/IP port or local Unix domain socket file extension on which `postgres` is to listen for connections from client applications. Defaults to the value of the `PGPORT` environment variable, or if `PGPORT` is not set, then defaults to the value established during compilation (normally 5432). If you specify a port other than the default port, then all client applications must specify the same port using either command-line options or `PGPORT`.

`-s`

Print time information and other statistics at the end of each command. This is useful for benchmarking or for use in tuning the number of buffers.

`-S work-mem`

Specifies the base amount of memory to be used by sorts and hash tables before resorting to temporary disk files. See the description of the `work_mem` configuration parameter in [Section 18.4.1](#).

`-V`

`--version`

Print the postgres version and exit.

`--name=value`

Sets a named run-time parameter; a shorter form of `-c`.

`--describe-config`

This option dumps out the server's internal configuration variables, descriptions, and defaults in tab-delimited `COPY` format. It is designed primarily for use by administration tools.

`-?`

`--help`

Show help about postgres command line arguments, and exit.

## Semi-Internal Options

The options described here are used mainly for debugging purposes, and in some cases to assist with recovery of severely damaged databases. There should be no reason to use them in a production database setup. They are listed here only for use by Postgres Pro system developers. Furthermore, these options might change or be removed in a future release without notice.

`-f { s | i | o | b | t | n | m | h }`

Forbids the use of particular scan and join methods: `s` and `i` disable sequential and index scans respectively, `o`, `b` and `t` disable index-only scans, bitmap index scans, and TID scans respectively, while `n`, `m`, and `h` disable nested-loop, merge and hash joins respectively.

Neither sequential scans nor nested-loop joins can be disabled completely; the `-fs` and `-fn` options simply discourage the optimizer from using those plan types if it has any other alternative.

- `-n`
- This option is for debugging problems that cause a server process to die abnormally. The ordinary strategy in this situation is to notify all other server processes that they must terminate and then reinitialize the shared memory and semaphores. This is because an errant server process could have corrupted some shared state before terminating. This option specifies that `postgres` will not reinitialize shared data structures. A knowledgeable system programmer can then use a debugger to examine shared memory and semaphore state.
- `-O`
- Allows the structure of system tables to be modified. This is used by `initdb`.
- `-P`
- Ignore system indexes when reading system tables, but still update the indexes when modifying the tables. This is useful when recovering from damaged system indexes.
- `-t pa[rser] | pl[anner] | e[xecutor]`
- Print timing statistics for each query relating to each of the major system modules. This option cannot be used together with the `-s` option.
- `-T`
- This option is for debugging problems that cause a server process to die abnormally. The ordinary strategy in this situation is to notify all other server processes that they must terminate and then reinitialize the shared memory and semaphores. This is because an errant server process could have corrupted some shared state before terminating. This option specifies that `postgres` will stop all other server processes by sending the signal `SIGSTOP`, but will not cause them to terminate. This permits system programmers to collect core dumps from all server processes by hand.
- `-v protocol`
- Specifies the version number of the frontend/backend protocol to be used for a particular session. This option is for internal use only.
- `-W seconds`
- A delay of this many seconds occurs when a new server process is started, after it conducts the authentication procedure. This is intended to give an opportunity to attach to the server process with a debugger.
- `-Z`
- Verifies that the current `postgres` binary is compatible with the specified cluster. If the architecture type or any compilation options that affect cluster compatibility do not match, returns an exit status of 1 and provides an error message specifying the first detected incompatibility. Otherwise, reports success and exits without starting the cluster.
- You must provide the path to the data directory of the cluster to check.
- The cluster and the binary must have the same byte order and architecture type for this option to work correctly.

**Tip**

If the binary appears to be incompatible with the specified cluster, run [pgpro\\_controldata](#) with the `-P` or `-C` command-line argument to view all parameters of the cluster that affect the compatibility.

**Options for Single-User Mode**

The following options only apply to the single-user mode (see [Single-User Mode](#) below).

`--single`

Selects the single-user mode. This must be the first argument on the command line.

`database`

Specifies the name of the database to be accessed. This must be the last argument on the command line. If it is omitted it defaults to the user name.

`-E`

Echo all commands to standard output before executing them.

`-j`

Use semicolon followed by two newlines, rather than just newline, as the command entry terminator.

`-r filename`

Send all server log output to *filename*. This option is only honored when supplied as a command-line option.

## Environment

PGCLIENTENCODING

Default character encoding used by clients. (The clients can override this individually.) This value can also be set in the configuration file.

PGDATA

Default data directory location

PGDATESTYLE

Default value of the [DateStyle](#) run-time parameter. (The use of this environment variable is deprecated.)

PGPORT

Default port number (preferably set in the configuration file)

## Diagnostics

A failure message mentioning `semget` or `shmget` probably indicates you need to configure your kernel to provide adequate shared memory and semaphores. For more discussion see [Section 17.4](#). You might be able to postpone reconfiguring your kernel by decreasing [shared\\_buffers](#) to reduce the shared memory consumption of Postgres Pro, and/or by reducing [max\\_connections](#) to reduce the semaphore consumption.

A failure message suggesting that another server is already running should be checked carefully, for example by using the command

```
$ ps ax | grep postgres
```

or

```
$ ps -ef | grep postgres
```

depending on your system. If you are certain that no conflicting server is running, you can remove the lock file mentioned in the message and try again.

A failure message indicating inability to bind to a port might indicate that that port is already in use by some non-Postgres Pro process. You might also get this error if you terminate `postgres` and immediately restart it using the same port; in this case, you must simply wait a few seconds until the operating system

closes the port before trying again. Finally, you might get this error if you specify a port number that your operating system considers to be reserved. For example, many versions of Unix consider port numbers under 1024 to be “trusted” and only permit the Unix superuser to access them.

## Notes

The utility command `pg_ctl` can be used to start and shut down the `postgres` server safely and comfortably.

If at all possible, *do not* use `SIGKILL` to kill the main `postgres` server. Doing so will prevent `postgres` from freeing the system resources (e.g., shared memory and semaphores) that it holds before terminating. This might cause problems for starting a fresh `postgres` run.

To terminate the `postgres` server normally, the signals `SIGTERM`, `SIGINT`, or `SIGHUP` can be used. The first will wait for all clients to terminate before quitting, the second will forcefully disconnect all clients, and the third will quit immediately without proper shutdown, resulting in a recovery run during restart.

The `SIGHUP` signal will reload the server configuration files. It is also possible to send `SIGHUP` to an individual server process, but that is usually not sensible.

To cancel a running query, send the `SIGINT` signal to the process running that command. To terminate a backend process cleanly, send `SIGTERM` to that process. See also `pg_cancel_backend` and `pg_terminate_backend` in [Section 9.27.2](#) for the SQL-callable equivalents of these two actions.

The `postgres` server uses `SIGHUP` to tell subordinate server processes to terminate without normal cleanup. This signal *should not* be used by users. It is also unwise to send `SIGKILL` to a server process — the main `postgres` process will interpret this as a crash and will force all the sibling processes to quit as part of its standard crash-recovery procedure.

## Bugs

The `--` options will not work on FreeBSD or OpenBSD. Use `-c` instead. This is a bug in the affected operating systems; a future release of Postgres Pro will provide a workaround if this is not fixed.

## Single-User Mode

To start a single-user mode server, use a command like

```
postgres --single -D /usr/local/pgsql/data other-options my_database
```

Provide the correct path to the database directory with `-D`, or make sure that the environment variable `PGDATA` is set. Also specify the name of the particular database you want to work in.

Normally, the single-user mode server treats newline as the command entry terminator; there is no intelligence about semicolons, as there is in `psql`. To continue a command across multiple lines, you must type backslash just before each newline except the last one. The backslash and adjacent newline are both dropped from the input command. Note that this will happen even when within a string literal or comment.

But if you use the `-j` command line switch, a single newline does not terminate command entry; instead, the sequence semicolon-newline-newline does. That is, type a semicolon immediately followed by a completely empty line. Backslash-newline is not treated specially in this mode. Again, there is no intelligence about such a sequence appearing within a string literal or comment.

In either input mode, if you type a semicolon that is not just before or part of a command entry terminator, it is considered a command separator. When you do type a command entry terminator, the multiple statements you've entered will be executed as a single transaction.

To quit the session, type EOF (**Control+D**, usually). If you've entered any text since the last command entry terminator, then EOF will be taken as a command entry terminator, and another EOF will be needed to exit.

Note that the single-user mode server does not provide sophisticated line-editing features (no command history, for example). Single-user mode also does not do any background processing, such as automatic checkpoints or replication.

## Examples

To start `postgres` in the background using default values, type:

```
$ nohup postgres >logfile 2>&1 </dev/null &
```

To start `postgres` with a specific port, e.g., 1234:

```
$ postgres -p 1234
```

To connect to this server using `psql`, specify this port with the `-p` option:

```
$ psql -p 1234
```

or set the environment variable `PGPORT`:

```
$ export PGPORT=1234
```

```
$ psql
```

Named run-time parameters can be set in either of these styles:

```
$ postgres -c work_mem=1234
```

```
$ postgres --work-mem=1234
```

Either form overrides whatever setting might exist for `work_mem` in `postgresql.conf`. Notice that underscores in parameter names can be written as either underscore or dash on the command line. Except for short-term experiments, it's probably better practice to edit the setting in `postgresql.conf` than to rely on a command-line switch to set a parameter.

# Chapter 48. Overview of Postgres Pro Internals

## Author

This chapter originated as part of [sim98](#), Stefan Simkovics' Master's Thesis prepared at Vienna University of Technology under the direction of O.Univ.Prof.Dr. Georg Gottlob and Univ.Ass. Mag. Katrin Seyr.

This chapter gives an overview of the internal structure of the backend of Postgres Pro. After having read the following sections you should have an idea of how a query is processed. This chapter does not aim to provide a detailed description of the internal operation of Postgres Pro, as such a document would be very extensive. Rather, this chapter is intended to help the reader understand the general sequence of operations that occur within the backend from the point at which a query is received, to the point at which the results are returned to the client.

## 48.1. The Path of a Query

Here we give a short overview of the stages a query has to pass in order to obtain a result.

1. A connection from an application program to the Postgres Pro server has to be established. The application program transmits a query to the server and waits to receive the results sent back by the server.
2. The *parser stage* checks the query transmitted by the application program for correct syntax and creates a *query tree*.
3. The *rewrite system* takes the query tree created by the parser stage and looks for any *rules* (stored in the *system catalogs*) to apply to the query tree. It performs the transformations given in the *rule bodies*.

One application of the rewrite system is in the realization of *views*. Whenever a query against a view (i.e., a *virtual table*) is made, the rewrite system rewrites the user's query to a query that accesses the *base tables* given in the *view definition* instead.

4. The *planner/optimizer* takes the (rewritten) query tree and creates a *query plan* that will be the input to the *executor*.

It does so by first creating all possible *paths* leading to the same result. For example if there is an index on a relation to be scanned, there are two paths for the scan. One possibility is a simple sequential scan and the other possibility is to use the index. Next the cost for the execution of each path is estimated and the cheapest path is chosen. The cheapest path is expanded into a complete plan that the executor can use.

5. The executor recursively steps through the *plan tree* and retrieves rows in the way represented by the plan. The executor makes use of the *storage system* while scanning relations, performs *sorts* and *joins*, evaluates *qualifications* and finally hands back the rows derived.

In the following sections we will cover each of the above listed items in more detail to give a better understanding of Postgres Pro's internal control and data structures.

## 48.2. How Connections Are Established

Postgres Pro is implemented using a simple “process per user” client/server model. In this model there is one *client process* connected to exactly one *server process*. As we do not know ahead of time how many connections will be made, we have to use a *master process* that spawns a new server process every time a connection is requested. This master process is called `postgres` and listens at a specified

TCP/IP port for incoming connections. Whenever a request for a connection is detected the `postgres` process spawns a new server process. The server tasks communicate with each other using *semaphores* and *shared memory* to ensure data integrity throughout concurrent data access.

The client process can be any program that understands the Postgres Pro protocol described in [Chapter 50](#). Many clients are based on the C-language library `libpq`, but several independent implementations of the protocol exist, such as the Java JDBC driver.

Once a connection is established the client process can send a query to the *backend* (server). The query is transmitted using plain text, i.e., there is no parsing done in the *frontend* (client). The server parses the query, creates an *execution plan*, executes the plan and returns the retrieved rows to the client by transmitting them over the established connection.

## 48.3. The Parser Stage

The *parser stage* consists of two parts:

- The *parser* defined in `gram.y` and `scan.l` is built using the Unix tools `bison` and `flex`.
- The *transformation process* does modifications and augmentations to the data structures returned by the parser.

### 48.3.1. Parser

The parser has to check the query string (which arrives as plain text) for valid syntax. If the syntax is correct a *parse tree* is built up and handed back; otherwise an error is returned. The parser and lexer are implemented using the well-known Unix tools `bison` and `flex`.

The *lexer* is defined in the file `scan.l` and is responsible for recognizing *identifiers*, the *SQL key words* etc. For every key word or identifier that is found, a *token* is generated and handed to the parser.

The parser is defined in the file `gram.y` and consists of a set of *grammar rules* and *actions* that are executed whenever a rule is fired. The code of the actions (which is actually C code) is used to build up the parse tree.

The file `scan.l` is transformed to the C source file `scan.c` using the program `flex` and `gram.y` is transformed to `gram.c` using `bison`. After these transformations have taken place a normal C compiler can be used to create the parser. Never make any changes to the generated C files as they will be overwritten the next time `flex` or `bison` is called.

#### Note

The mentioned transformations and compilations are normally done automatically using the *makefiles* shipped with the Postgres Pro source distribution.

A detailed description of `bison` or the grammar rules given in `gram.y` would be beyond the scope of this paper. There are many books and documents dealing with `flex` and `bison`. You should be familiar with `bison` before you start to study the grammar given in `gram.y` otherwise you won't understand what happens there.

### 48.3.2. Transformation Process

The parser stage creates a parse tree using only fixed rules about the syntactic structure of SQL. It does not make any lookups in the system catalogs, so there is no possibility to understand the detailed semantics of the requested operations. After the parser completes, the *transformation process* takes the tree handed back by the parser as input and does the semantic interpretation needed to understand which tables, functions, and operators are referenced by the query. The data structure that is built to represent this information is called the *query tree*.

The reason for separating raw parsing from semantic analysis is that system catalog lookups can only be done within a transaction, and we do not wish to start a transaction immediately upon receiving a query string. The raw parsing stage is sufficient to identify the transaction control commands (`BEGIN`, `ROLLBACK`, etc), and these can then be correctly executed without any further analysis. Once we know that we are dealing with an actual query (such as `SELECT` or `UPDATE`), it is okay to start a transaction if we're not already in one. Only then can the transformation process be invoked.

The query tree created by the transformation process is structurally similar to the raw parse tree in most places, but it has many differences in detail. For example, a `FuncCall` node in the parse tree represents something that looks syntactically like a function call. This might be transformed to either a `FuncExpr` or `Aggref` node depending on whether the referenced name turns out to be an ordinary function or an aggregate function. Also, information about the actual data types of columns and expression results is added to the query tree.

## 48.4. The Postgres Pro Rule System

Postgres Pro supports a powerful *rule system* for the specification of *views* and ambiguous *view updates*. Originally the Postgres Pro rule system consisted of two implementations:

- The first one worked using *row level* processing and was implemented deep in the *executor*. The rule system was called whenever an individual row had been accessed. This implementation was removed in 1995 when the last official release of the Berkeley Postgres project was transformed into Postgres95.
- The second implementation of the rule system is a technique called *query rewriting*. The *rewrite system* is a module that exists between the *parser stage* and the *planner/optimizer*. This technique is still implemented.

The query rewriter is discussed in some detail in [Chapter 38](#), so there is no need to cover it here. We will only point out that both the input and the output of the rewriter are query trees, that is, there is no change in the representation or level of semantic detail in the trees. Rewriting can be thought of as a form of macro expansion.

## 48.5. Planner/Optimizer

The task of the *planner/optimizer* is to create an optimal execution plan. A given SQL query (and hence, a query tree) can be actually executed in a wide variety of different ways, each of which will produce the same set of results. If it is computationally feasible, the query optimizer will examine each of these possible execution plans, ultimately selecting the execution plan that is expected to run the fastest.

### Note

In some situations, examining each possible way in which a query can be executed would take an excessive amount of time and memory space. In particular, this occurs when executing queries involving large numbers of join operations. In order to determine a reasonable (not necessarily optimal) query plan in a reasonable amount of time, Postgres Pro uses a *Genetic Query Optimizer* (see [Chapter 55](#)) when the number of joins exceeds a threshold (see `geqo_threshold`).

The planner's search procedure actually works with data structures called *paths*, which are simply cut-down representations of plans containing only as much information as the planner needs to make its decisions. After the cheapest path is determined, a full-fledged *plan tree* is built to pass to the executor. This represents the desired execution plan in sufficient detail for the executor to run it. In the rest of this section we'll ignore the distinction between paths and plans.

### 48.5.1. Generating Possible Plans

The planner/optimizer starts by generating plans for scanning each individual relation (table) used in the query. The possible plans are determined by the available indexes on each relation. There is always

the possibility of performing a sequential scan on a relation, so a sequential scan plan is always created. Assume an index is defined on a relation (for example a B-tree index) and a query contains the restriction `relation.attribute OPR constant`. If `relation.attribute` happens to match the key of the B-tree index and `OPR` is one of the operators listed in the index's *operator class*, another plan is created using the B-tree index to scan the relation. If there are further indexes present and the restrictions in the query happen to match a key of an index, further plans will be considered. Index scan plans are also generated for indexes that have a sort ordering that can match the query's `ORDER BY` clause (if any), or a sort ordering that might be useful for merge joining (see below).

If the query requires joining two or more relations, plans for joining relations are considered after all feasible plans have been found for scanning single relations. The three available join strategies are:

- *nested loop join*: The right relation is scanned once for every row found in the left relation. This strategy is easy to implement but can be very time consuming. (However, if the right relation can be scanned with an index scan, this can be a good strategy. It is possible to use values from the current row of the left relation as keys for the index scan of the right.)
- *merge join*: Each relation is sorted on the join attributes before the join starts. Then the two relations are scanned in parallel, and matching rows are combined to form join rows. This kind of join is more attractive because each relation has to be scanned only once. The required sorting might be achieved either by an explicit sort step, or by scanning the relation in the proper order using an index on the join key.
- *hash join*: the right relation is first scanned and loaded into a hash table, using its join attributes as hash keys. Next the left relation is scanned and the appropriate values of every row found are used as hash keys to locate the matching rows in the table.

When the query involves more than two relations, the final result must be built up by a tree of join steps, each with two inputs. The planner examines different possible join sequences to find the cheapest one.

If the query uses fewer than `geqo_threshold` relations, a near-exhaustive search is conducted to find the best join sequence. The planner preferentially considers joins between any two relations for which there exist a corresponding join clause in the `WHERE` qualification (i.e., for which a restriction like `where rel1.attr1=rel2.attr2` exists). Join pairs with no join clause are considered only when there is no other choice, that is, a particular relation has no available join clauses to any other relation. All possible plans are generated for every join pair considered by the planner, and the one that is (estimated to be) the cheapest is chosen.

When `geqo_threshold` is exceeded, the join sequences considered are determined by heuristics, as described in [Chapter 55](#). Otherwise the process is the same.

The finished plan tree consists of sequential or index scans of the base relations, plus nested-loop, merge, or hash join nodes as needed, plus any auxiliary steps needed, such as sort nodes or aggregate-function calculation nodes. Most of these plan node types have the additional ability to do *selection* (discarding rows that do not meet a specified Boolean condition) and *projection* (computation of a derived column set based on given column values, that is, evaluation of scalar expressions where needed). One of the responsibilities of the planner is to attach selection conditions from the `WHERE` clause and computation of required output expressions to the most appropriate nodes of the plan tree.

## 48.6. Executor

The *executor* takes the plan created by the planner/optimizer and recursively processes it to extract the required set of rows. This is essentially a demand-pull pipeline mechanism. Each time a plan node is called, it must deliver one more row, or report that it is done delivering rows.

To provide a concrete example, assume that the top node is a `MergeJoin` node. Before any merge can be done two rows have to be fetched (one from each subplan). So the executor recursively calls itself to process the subplans (it starts with the subplan attached to `lefttree`). The new top node (the top node of the left subplan) is, let's say, a `Sort` node and again recursion is needed to obtain an input row. The child node of the `Sort` might be a `SeqScan` node, representing actual reading of a table. Execution of this

node causes the executor to fetch a row from the table and return it up to the calling node. The `Sort` node will repeatedly call its child to obtain all the rows to be sorted. When the input is exhausted (as indicated by the child node returning a `NULL` instead of a row), the `Sort` code performs the sort, and finally is able to return its first output row, namely the first one in sorted order. It keeps the remaining rows stored so that it can deliver them in sorted order in response to later demands.

The `MergeJoin` node similarly demands the first row from its right subplan. Then it compares the two rows to see if they can be joined; if so, it returns a join row to its caller. On the next call, or immediately if it cannot join the current pair of inputs, it advances to the next row of one table or the other (depending on how the comparison came out), and again checks for a match. Eventually, one subplan or the other is exhausted, and the `MergeJoin` node returns `NULL` to indicate that no more join rows can be formed.

Complex queries can involve many levels of plan nodes, but the general approach is the same: each node computes and returns its next output row each time it is called. Each node is also responsible for applying any selection or projection expressions that were assigned to it by the planner.

The executor mechanism is used to evaluate all four basic SQL query types: `SELECT`, `INSERT`, `UPDATE`, and `DELETE`. For `SELECT`, the top-level executor code only needs to send each row returned by the query plan tree off to the client. `INSERT ... SELECT`, `UPDATE`, and `DELETE` are effectively `SELECTS` under a special top-level plan node called `ModifyTable`.

`INSERT ... SELECT` feeds the rows up to `ModifyTable` for insertion. For `UPDATE`, the planner arranges that each computed row includes all the updated column values, plus the *TID* (tuple ID, or row ID) of the original target row; this data is fed up to the `ModifyTable` node, which uses the information to create a new updated row and mark the old row deleted. For `DELETE`, the only column that is actually returned by the plan is the TID, and the `ModifyTable` node simply uses the TID to visit each target row and mark it deleted.

A simple `INSERT ... VALUES` command creates a trivial plan tree consisting of a single `Result` node, which computes just one result row, feeding that up to `ModifyTable` to perform the insertion.

---

# Chapter 49. System Catalogs

The system catalogs are the place where a relational database management system stores schema metadata, such as information about tables and columns, and internal bookkeeping information. Postgres Pro's system catalogs are regular tables. You can drop and recreate the tables, add columns, insert and update values, and severely mess up your system that way. Normally, one should not change the system catalogs by hand, there are normally SQL commands to do that. (For example, `CREATE DATABASE` inserts a row into the `pg_database` catalog — and actually creates the database on disk.) There are some exceptions for particularly esoteric operations, but many of those have been made available as SQL commands over time, and so the need for direct manipulation of the system catalogs is ever decreasing.

## 49.1. Overview

Table 49.1 lists the system catalogs. More detailed documentation of each catalog follows below.

Most system catalogs are copied from the template database during database creation and are thereafter database-specific. A few catalogs are physically shared across all databases in a cluster; these are noted in the descriptions of the individual catalogs.

**Table 49.1. System Catalogs**

Catalog Name	Purpose
<code>pg_aggregate</code>	aggregate functions
<code>pg_am</code>	relation access methods
<code>pg_amop</code>	access method operators
<code>pg_amproc</code>	access method support functions
<code>pg_attrdef</code>	column default values
<code>pg_attribute</code>	table columns (“attributes”)
<code>pg_authid</code>	authorization identifiers (roles)
<code>pg_auth_members</code>	authorization identifier membership relationships
<code>pg_cast</code>	casts (data type conversions)
<code>pg_class</code>	tables, indexes, sequences, views (“relations”)
<code>pg_collation</code>	collations (locale information)
<code>pg_constraint</code>	check constraints, unique constraints, primary key constraints, foreign key constraints
<code>pg_conversion</code>	encoding conversion information
<code>pg_database</code>	databases within this database cluster
<code>pg_db_role_setting</code>	per-role and per-database settings
<code>pg_default_acl</code>	default privileges for object types
<code>pg_depend</code>	dependencies between database objects
<code>pg_description</code>	descriptions or comments on database objects
<code>pg_enum</code>	enum label and value definitions
<code>pg_event_trigger</code>	event triggers
<code>pg_extension</code>	installed extensions
<code>pg_foreign_data_wrapper</code>	foreign-data wrapper definitions
<code>pg_foreign_server</code>	foreign server definitions
<code>pg_foreign_table</code>	additional foreign table information
<code>pg_index</code>	additional index information

<b>Catalog Name</b>	<b>Purpose</b>
<code>pg_inherits</code>	table inheritance hierarchy
<code>pg_init_privs</code>	object initial privileges
<code>pg_language</code>	languages for writing functions
<code>pg_largeobject</code>	data pages for large objects
<code>pg_largeobject_metadata</code>	metadata for large objects
<code>pg_namespace</code>	schemas
<code>pg_opclass</code>	access method operator classes
<code>pg_operator</code>	operators
<code>pg_opfamily</code>	access method operator families
<code>pg_partitioned_table</code>	information about partition key of tables
<code>pg_policy</code>	row-security policies
<code>pg_proc</code>	functions and procedures
<code>pg_publication</code>	publications for logical replication
<code>pg_publication_rel</code>	relation to publication mapping
<code>pg_range</code>	information about range types
<code>pg_replication_origin</code>	registered replication origins
<code>pg_rewrite</code>	query rewrite rules
<code>pg_seclabel</code>	security labels on database objects
<code>pg_sequence</code>	information about sequences
<code>pg_shdepend</code>	dependencies on shared objects
<code>pg_shdescription</code>	comments on shared objects
<code>pg_shseclabel</code>	security labels on shared database objects
<code>pg_statistic</code>	planner statistics
<code>pg_statistic_ext</code>	extended planner statistics (definition)
<code>pg_statistic_ext_data</code>	extended planner statistics (built statistics)
<code>pg_subscription</code>	logical replication subscriptions
<code>pg_subscription_rel</code>	relation state for subscriptions
<code>pg_tablespace</code>	tablespaces within this database cluster
<code>pg_transform</code>	transforms (data type to procedural language conversions)
<code>pg_trigger</code>	triggers
<code>pg_ts_config</code>	text search configurations
<code>pg_ts_config_map</code>	text search configurations' token mappings
<code>pg_ts_dict</code>	text search dictionaries
<code>pg_ts_parser</code>	text search parsers
<code>pg_ts_template</code>	text search templates
<code>pg_type</code>	data types
<code>pg_user_mapping</code>	mappings of users to foreign servers

## 49.2. pg\_aggregate

The catalog `pg_aggregate` stores information about aggregate functions. An aggregate function is a function that operates on a set of values (typically one column from each row that matches a query condition) and returns a single value computed from all these values. Typical aggregate functions are `sum`, `count`, and `max`. Each entry in `pg_aggregate` is an extension of an entry in `pg_proc`. The `pg_proc` entry carries the aggregate's name, input and output data types, and other information that is similar to ordinary functions.

**Table 49.2. `pg_aggregate` Columns**

<b>Column Type</b>	<b>Description</b>
<code>aggfnoid regproc (references <code>pg_proc</code> .oid)</code> <code>pg_proc</code> OID of the aggregate function	
<code>aggkind char</code>	Aggregate kind: <code>n</code> for “normal” aggregates, <code>o</code> for “ordered-set” aggregates, or <code>h</code> for “hypothetical-set” aggregates
<code>aggnumdirectargs int2</code>	Number of direct (non-aggregated) arguments of an ordered-set or hypothetical-set aggregate, counting a variadic array as one argument. If equal to <code>pronargs</code> , the aggregate must be variadic and the variadic array describes the aggregated arguments as well as the final direct arguments. Always zero for normal aggregates.
<code>aggtransfn regproc (references <code>pg_proc</code> .oid)</code>	Transition function
<code>aggfinalfn regproc (references <code>pg_proc</code> .oid)</code>	Final function (zero if none)
<code>aggcombinefn regproc (references <code>pg_proc</code> .oid)</code>	Combine function (zero if none)
<code>aggserialfn regproc (references <code>pg_proc</code> .oid)</code>	Serialization function (zero if none)
<code>aggdeserialfn regproc (references <code>pg_proc</code> .oid)</code>	Deserialization function (zero if none)
<code>aggmtransfn regproc (references <code>pg_proc</code> .oid)</code>	Forward transition function for moving-aggregate mode (zero if none)
<code>aggminvtransfn regproc (references <code>pg_proc</code> .oid)</code>	Inverse transition function for moving-aggregate mode (zero if none)
<code>aggmfinalfn regproc (references <code>pg_proc</code> .oid)</code>	Final function for moving-aggregate mode (zero if none)
<code>aggfinalextra bool</code>	True to pass extra dummy arguments to <code>aggfinalfn</code>
<code>aggmfinalextra bool</code>	True to pass extra dummy arguments to <code>aggmfinalfn</code>
<code>aggfinalmodify char</code>	Whether <code>aggfinalfn</code> modifies the transition state value: <code>r</code> if it is read-only, <code>s</code> if the <code>aggtransfn</code> cannot be applied after the <code>aggfinalfn</code> , or <code>w</code> if it writes on the value
<code>aggmfinalmodify char</code>	Like <code>aggfinalmodify</code> , but for the <code>aggmfinalfn</code>
<code>aggsortop oid (references <code>pg_operator</code> .oid)</code>	Associated sort operator (zero if none)
<code>aggtranstype oid (references <code>pg_type</code> .oid)</code>	Data type of the aggregate function's internal transition (state) data
<code>aggtransspace int4</code>	

Column Type	Description
	Approximate average size (in bytes) of the transition state data, or zero to use a default estimate
aggmtranstype oid (references <a href="#">pg_type</a> .oid)	Data type of the aggregate function's internal transition (state) data for moving-aggregate mode (zero if none)
aggmtransspace int4	Approximate average size (in bytes) of the transition state data for moving-aggregate mode, or zero to use a default estimate
agginitval text	The initial value of the transition state. This is a text field containing the initial value in its external string representation. If this field is null, the transition state value starts out null.
aggminitval text	The initial value of the transition state for moving-aggregate mode. This is a text field containing the initial value in its external string representation. If this field is null, the transition state value starts out null.

New aggregate functions are registered with the [CREATE AGGREGATE](#) command. See [Section 35.12](#) for more information about writing aggregate functions and the meaning of the transition functions, etc.

### 49.3. pg\_am

The catalog `pg_am` stores information about relation access methods. There is one row for each access method supported by the system. Currently, only tables and indexes have access methods. The requirements for table and index access methods are discussed in detail in [Chapter 56](#) and [Chapter 57](#) respectively.

**Table 49.3. pg\_am Columns**

Column Type	Description
oid oid	Row identifier
amname name	Name of the access method
amhandler regproc (references <a href="#">pg_proc</a> .oid)	OID of a handler function that is responsible for supplying information about the access method
amtype char	t = table (including materialized views), i = index.

#### Note

Before Postgres Pro 9.6, `pg_am` contained many additional columns representing properties of index access methods. That data is now only directly visible at the C code level. However, `pg_index_column_has_property()` and related functions have been added to allow SQL queries to inspect index access method properties; see [Table 9.68](#).

### 49.4. pg\_amop

The catalog `pg_amop` stores information about operators associated with access method operator families. There is one row for each operator that is a member of an operator family. A family member can

be either a *search* operator or an *ordering* operator. An operator can appear in more than one family, but cannot appear in more than one search position nor more than one ordering position within a family. (It is allowed, though unlikely, for an operator to be used for both search and ordering purposes.)

**Table 49.4. pg\_amop Columns**

Column Type	Description
oid oid	Row identifier
amopfamily oid (references <a href="#">pg_opfamily</a> .oid)	The operator family this entry is for
amoplefttype oid (references <a href="#">pg_type</a> .oid)	Left-hand input data type of operator
amoprightrighttype oid (references <a href="#">pg_type</a> .oid)	Right-hand input data type of operator
amopstrategy int2	Operator strategy number
amoppurpose char	Operator purpose, either <i>s</i> for search or <i>o</i> for ordering
amopopr oid (references <a href="#">pg_operator</a> .oid)	OID of the operator
amopmethod oid (references <a href="#">pg_am</a> .oid)	Index access method operator family is for
amopsortfamily oid (references <a href="#">pg_opfamily</a> .oid)	The B-tree operator family this entry sorts according to, if an ordering operator; zero if a search operator

A “search” operator entry indicates that an index of this operator family can be searched to find all rows satisfying `WHERE indexed_column operator constant`. Obviously, such an operator must return `boolean`, and its left-hand input type must match the index's column data type.

An “ordering” operator entry indicates that an index of this operator family can be scanned to return rows in the order represented by `ORDER BY indexed_column operator constant`. Such an operator could return any sortable data type, though again its left-hand input type must match the index's column data type. The exact semantics of the `ORDER BY` are specified by the `amopsortfamily` column, which must reference a B-tree operator family for the operator's result type.

### Note

At present, it's assumed that the sort order for an ordering operator is the default for the referenced operator family, i.e., `ASC NULLS LAST`. This might someday be relaxed by adding additional columns to specify sort options explicitly.

An entry's `amopmethod` must match the `opfmethod` of its containing operator family (including `amopmethod` here is an intentional denormalization of the catalog structure for performance reasons). Also, `amoplefttype` and `amoprightrighttype` must match the `oprleft` and `oprright` fields of the referenced `pg_operator` entry.

## 49.5. pg\_amproc

The catalog `pg_amproc` stores information about support functions associated with access method operator families. There is one row for each support function belonging to an operator family.

**Table 49.5. pg\_amproc Columns**

Column Type	Description
oid oid	Row identifier
amprocfamily oid (references <a href="#">pg_opfamily</a> .oid)	The operator family this entry is for
amproclefttype oid (references <a href="#">pg_type</a> .oid)	Left-hand input data type of associated operator
amprocrighttype oid (references <a href="#">pg_type</a> .oid)	Right-hand input data type of associated operator
amprocnum int2	Support function number
amproc regproc (references <a href="#">pg_proc</a> .oid)	OID of the function

The usual interpretation of the `amproclefttype` and `amprocrighttype` fields is that they identify the left and right input types of the operator(s) that a particular support function supports. For some access methods these match the input data type(s) of the support function itself, for others not. There is a notion of “default” support functions for an index, which are those with `amproclefttype` and `amprocrighttype` both equal to the index operator class's `opcintype`.

## 49.6. pg\_attrdef

The catalog `pg_attrdef` stores column default values. The main information about columns is stored in `pg_attribute`. Only columns for which a default value has been explicitly set will have an entry here.

**Table 49.6. pg\_attrdef Columns**

Column Type	Description
oid oid	Row identifier
adrelid oid (references <a href="#">pg_class</a> .oid)	The table this column belongs to
adnum int2 (references <a href="#">pg_attribute</a> .attnum)	The number of the column
adbin pg_node_tree	The column default value, in <code>nodeToString()</code> representation. Use <code>pg_get_expr(adbin, adrelid)</code> to convert it to an SQL expression.

## 49.7. pg\_attribute

The catalog `pg_attribute` stores information about table columns. There will be exactly one `pg_attribute` row for every column in every table in the database. (There will also be attribute entries for indexes, and indeed all objects that have `pg_class` entries.)

The term `attribute` is equivalent to `column` and is used for historical reasons.

**Table 49.7. pg\_attribute Columns**

Column Type	Description
attrelid oid (references <a href="#">pg_class</a> .oid)	The table this column belongs to

<b>Column Type</b>	<b>Description</b>
<code>attname</code> name	The column name
<code>atttypid</code> oid (references <code>pg_type</code> .oid)	The data type of this column
<code>attstattarget</code> int4	<code>attstattarget</code> controls the level of detail of statistics accumulated for this column by <code>ANALYZE</code> . A zero value indicates that no statistics should be collected. A negative value says to use the system default statistics target. The exact meaning of positive values is data type-dependent. For scalar data types, <code>attstattarget</code> is both the target number of “most common values” to collect, and the target number of histogram bins to create.
<code>attlen</code> int2	A copy of <code>pg_type.typelen</code> of this column's type
<code>attnum</code> int2	The number of the column. Ordinary columns are numbered from 1 up. System columns, such as <code>ctid</code> , have (arbitrary) negative numbers.
<code>atndims</code> int4	Number of dimensions, if the column is an array type; otherwise 0. (Presently, the number of dimensions of an array is not enforced, so any nonzero value effectively means “it's an array”.)
<code>attcacheoff</code> int4	Always -1 in storage, but when loaded into a row descriptor in memory this might be updated to cache the offset of the attribute within the row
<code>atttypmod</code> int4	<code>atttypmod</code> records type-specific data supplied at table creation time (for example, the maximum length of a <code>varchar</code> column). It is passed to type-specific input functions and length coercion functions. The value will generally be -1 for types that do not need <code>atttypmod</code> .
<code>attbyval</code> bool	A copy of <code>pg_type.typbyval</code> of this column's type
<code>attstorage</code> char	Normally a copy of <code>pg_type.typstorage</code> of this column's type. For TOAST-able data types, this can be altered after column creation to control storage policy.
<code>attalign</code> char	A copy of <code>pg_type.typalign</code> of this column's type
<code>attnotnull</code> bool	This represents a not-null constraint.
<code>atthasdef</code> bool	This column has a default expression or generation expression, in which case there will be a corresponding entry in the <code>pg_attrdef</code> catalog that actually defines the expression. (Check <code>attgenerated</code> to determine whether this is a default or a generation expression.)
<code>atthasmissing</code> bool	This column has a value which is used where the column is entirely missing from the row, as happens when a column is added with a non-volatile <code>DEFAULT</code> value after the row is created. The actual value used is stored in the <code>attmissingval</code> column.
<code>attidentity</code> char	If a zero byte (' '), then not an identity column. Otherwise, a = generated always, d = generated by default.
<code>attgenerated</code> char	

Column Type	Description
	If a zero byte (' '), then not a generated column. Otherwise, <i>s</i> = stored. (Other values might be added in the future.)
<code>attisdropped</code> bool	This column has been dropped and is no longer valid. A dropped column is still physically present in the table, but is ignored by the parser and so cannot be accessed via SQL.
<code>attislocal</code> bool	This column is defined locally in the relation. Note that a column can be locally defined and inherited simultaneously.
<code>attinhcount</code> int4	The number of direct ancestors this column has. A column with a nonzero number of ancestors cannot be dropped nor renamed.
<code>attcollation</code> oid (references <code>pg_collation</code> .oid)	The defined collation of the column, or zero if the column is not of a collatable data type.
<code>attacl</code> aclitem[]	Column-level access privileges, if any have been granted specifically on this column
<code>attoptions</code> text[]	Attribute-level options, as “keyword=value” strings
<code>attfdwoptions</code> text[]	Attribute-level foreign data wrapper options, as “keyword=value” strings
<code>attmissingval</code> anyarray	This column has a one element array containing the value used when the column is entirely missing from the row, as happens when the column is added with a non-volatile <code>DEFAULT</code> value after the row is created. The value is only used when <code>atthasmissing</code> is true. If there is no value the column is null.

In a dropped column's `pg_attribute` entry, `atttypid` is reset to zero, but `attlen` and the other fields copied from `pg_type` are still valid. This arrangement is needed to cope with the situation where the dropped column's data type was later dropped, and so there is no `pg_type` row anymore. `attlen` and the other fields can be used to interpret the contents of a row of the table.

## 49.8. `pg_authid`

The catalog `pg_authid` contains information about database authorization identifiers (roles). A role subsumes the concepts of “users” and “groups”. A user is essentially just a role with the `rolcanlogin` flag set. Any role (with or without `rolcanlogin`) can have other roles as members; see `pg_auth_members`.

Since this catalog contains passwords, it must not be publicly readable. `pg_roles` is a publicly readable view on `pg_authid` that blanks out the password field.

[Chapter 20](#) contains detailed information about user and privilege management.

Because user identities are cluster-wide, `pg_authid` is shared across all databases of a cluster: there is only one copy of `pg_authid` per cluster, not one per database.

**Table 49.8. `pg_authid` Columns**

Column Type	Description
<code>oid</code> oid	Row identifier
<code>rolname</code> name	Role name

Column Type	Description
<code>rolsuper</code> bool	Role has superuser privileges
<code>rolinherit</code> bool	Role automatically inherits privileges of roles it is a member of
<code>rolcreatorole</code> bool	Role can create more roles
<code>rolcreatedb</code> bool	Role can create databases
<code>rolcanlogin</code> bool	Role can log in. That is, this role can be given as the initial session authorization identifier.
<code>rolreplication</code> bool	Role is a replication role. A replication role can initiate replication connections and create and drop replication slots.
<code>rolbypassrls</code> bool	Role bypasses every row level security policy, see <a href="#">Section 5.8</a> for more information.
<code>rolconlimit</code> int4	For roles that can log in, this sets maximum number of concurrent connections this role can make. -1 means no limit.
<code>rolpassword</code> text	Password (possibly encrypted); null if none. The format depends on the form of encryption used.
<code>rolvaliduntil</code> timestampz	Password expiry time (only used for password authentication); null if no expiration

For an MD5 encrypted password, `rolpassword` column will begin with the string `md5` followed by a 32-character hexadecimal MD5 hash. The MD5 hash will be of the user's password concatenated to their user name. For example, if user `joe` has password `xyzyz`, Postgres Pro will store the md5 hash of `xyzyzjoe`.

If the password is encrypted with SCRAM-SHA-256, it has the format:

```
SCRAM-SHA-256$<iteration count>:<salt>$<StoredKey>:<ServerKey>
```

where `salt`, `StoredKey` and `ServerKey` are in Base64 encoded format. This format is the same as that specified by RFC 5803.

A password that does not follow either of those formats is assumed to be unencrypted.

## 49.9. pg\_auth\_members

The catalog `pg_auth_members` shows the membership relations between roles. Any non-circular set of relationships is allowed.

Because user identities are cluster-wide, `pg_auth_members` is shared across all databases of a cluster: there is only one copy of `pg_auth_members` per cluster, not one per database.

**Table 49.9. pg\_auth\_members Columns**

Column Type	Description
<code>roleid</code> oid (references <code>pg_authid</code> .oid)	ID of a role that has a member
<code>member</code> oid (references <code>pg_authid</code> .oid)	ID of a role that is a member of <code>roleid</code>

Column Type	Description
grantor oid (references <code>pg_authid</code> .oid)	ID of the role that granted this membership
admin_option bool	True if member can grant membership in <code>roleid</code> to others

## 49.10. pg\_cast

The catalog `pg_cast` stores data type conversion paths, both built-in and user-defined.

It should be noted that `pg_cast` does not represent every type conversion that the system knows how to perform; only those that cannot be deduced from some generic rule. For example, casting between a domain and its base type is not explicitly represented in `pg_cast`. Another important exception is that “automatic I/O conversion casts”, those performed using a data type's own I/O functions to convert to or from `text` or other string types, are not explicitly represented in `pg_cast`.

**Table 49.10. pg\_cast Columns**

Column Type	Description
oid oid	Row identifier
castsource oid (references <code>pg_type</code> .oid)	OID of the source data type
casttarget oid (references <code>pg_type</code> .oid)	OID of the target data type
castfunc oid (references <code>pg_proc</code> .oid)	The OID of the function to use to perform this cast. Zero is stored if the cast method doesn't require a function.
castcontext char	Indicates what contexts the cast can be invoked in. <code>e</code> means only as an explicit cast (using <code>CAST</code> or <code>::</code> syntax). <code>a</code> means implicitly in assignment to a target column, as well as explicitly. <code>i</code> means implicitly in expressions, as well as the other cases.
castmethod char	Indicates how the cast is performed. <code>f</code> means that the function specified in the <code>castfunc</code> field is used. <code>i</code> means that the input/output functions are used. <code>b</code> means that the types are binary-coercible, thus no conversion is required.

The cast functions listed in `pg_cast` must always take the cast source type as their first argument type, and return the cast destination type as their result type. A cast function can have up to three arguments. The second argument, if present, must be type `integer`; it receives the type modifier associated with the destination type, or -1 if there is none. The third argument, if present, must be type `boolean`; it receives `true` if the cast is an explicit cast, `false` otherwise.

It is legitimate to create a `pg_cast` entry in which the source and target types are the same, if the associated function takes more than one argument. Such entries represent “length coercion functions” that coerce values of the type to be legal for a particular type modifier value.

When a `pg_cast` entry has different source and target types and a function that takes more than one argument, it represents converting from one type to another and applying a length coercion in a single step. When no such entry is available, coercion to a type that uses a type modifier involves two steps, one to convert between data types and a second to apply the modifier.

## 49.11. pg\_class

The catalog `pg_class` catalogs tables and most everything else that has columns or is otherwise similar to a table. This includes indexes (but see also `pg_index`), sequences (but see also `pg_sequence`), views, materialized views, composite types, and TOAST tables; see `relkind`. Below, when we mean all of these kinds of objects we speak of “relations”. Not all columns are meaningful for all relation types.

**Table 49.11. `pg_class` Columns**

Column Type	Description
<code>oid oid</code>	Row identifier
<code>relname name</code>	Name of the table, index, view, etc.
<code>relnamespace oid (references <code>pg_namespace</code> .oid)</code>	The OID of the namespace that contains this relation
<code>reltype oid (references <code>pg_type</code> .oid)</code>	The OID of the data type that corresponds to this table's row type, if any (zero for indexes, which have no <code>pg_type</code> entry)
<code>reloftype oid (references <code>pg_type</code> .oid)</code>	For typed tables, the OID of the underlying composite type, zero for all other relations
<code>relowner oid (references <code>pg_authid</code> .oid)</code>	Owner of the relation
<code>relam oid (references <code>pg_am</code> .oid)</code>	If this is a table or an index, the access method used (heap, B-tree, hash, etc.)
<code>relfilenode oid</code>	Name of the on-disk file of this relation; zero means this is a “mapped” relation whose disk file name is determined by low-level state
<code>reltablespace oid (references <code>pg_tablespace</code> .oid)</code>	The tablespace in which this relation is stored. If zero, the database's default tablespace is implied. (Not meaningful if the relation has no on-disk file.)
<code>relpages int4</code>	Size of the on-disk representation of this table in pages (of size <code>BLCKSZ</code> ). This is only an estimate used by the planner. It is updated by <code>VACUUM</code> , <code>ANALYZE</code> , and a few DDL commands such as <code>CREATE INDEX</code> .
<code>reltuples float4</code>	Number of live rows in the table. This is only an estimate used by the planner. It is updated by <code>VACUUM</code> , <code>ANALYZE</code> , and a few DDL commands such as <code>CREATE INDEX</code> .
<code>relallvisible int4</code>	Number of pages that are marked all-visible in the table's visibility map. This is only an estimate used by the planner. It is updated by <code>VACUUM</code> , <code>ANALYZE</code> , and a few DDL commands such as <code>CREATE INDEX</code> .
<code>reltoastrelid oid (references <code>pg_class</code> .oid)</code>	OID of the TOAST table associated with this table, 0 if none. The TOAST table stores large attributes “out of line” in a secondary table.
<code>relhasindex bool</code>	True if this is a table and it has (or recently had) any indexes
<code>relisshared bool</code>	True if this table is shared across all databases in the cluster. Only certain system catalogs (such as <code>pg_database</code> ) are shared.
<code>relpersistence char</code>	<code>p</code> = permanent table, <code>u</code> = unlogged table, <code>t</code> = temporary table

<b>Column Type</b>	<b>Description</b>
relkind char	r = ordinary table, i = index, S = sequence, t = TOAST table, v = view, m = materialized view, c = composite type, f = foreign table, p = partitioned table, I = partitioned index
relnatts int2	Number of user columns in the relation (system columns not counted). There must be this many corresponding entries in <code>pg_attribute</code> . See also <code>pg_attribute.attnum</code> .
relchecks int2	Number of CHECK constraints on the table; see <code>pg_constraint</code> catalog
relhasrules bool	True if table has (or once had) rules; see <code>pg_rewrite</code> catalog
relhastriggers bool	True if table has (or once had) triggers; see <code>pg_trigger</code> catalog
relhassubclass bool	True if table or index has (or once had) any inheritance children
relrowsecurity bool	True if table has row level security enabled; see <code>pg_policy</code> catalog
relforcerowsecurity bool	True if row level security (when enabled) will also apply to table owner; see <code>pg_policy</code> catalog
relispopulated bool	True if relation is populated (this is true for all relations other than some materialized views)
relreplident char	Columns used to form “replica identity” for rows: d = default (primary key, if any), n = nothing, f = all columns, i = index with <code>indisreplident</code> set (same as nothing if the index used has been dropped)
relispartition bool	True if table or index is a partition
relrewrite oid (references <code>pg_class.oid</code> )	For new relations being written during a DDL operation that requires a table rewrite, this contains the OID of the original relation; otherwise 0. That state is only visible internally; this field should never contain anything other than 0 for a user-visible relation.
relfrozenxid xid	All transaction IDs before this one have been replaced with a permanent (“frozen”) transaction ID in this table. This is used to track whether the table needs to be vacuumed in order to prevent transaction ID wraparound or to allow <code>pg_xact</code> to be shrunk. Zero ( <code>InvalidTransactionId</code> ) if the relation is not a table.
relminmxid xid	All multixact IDs before this one have been replaced by a transaction ID in this table. This is used to track whether the table needs to be vacuumed in order to prevent multixact ID wraparound or to allow <code>pg_multixact</code> to be shrunk. Zero ( <code>InvalidMultiXactId</code> ) if the relation is not a table.
relacl aclitem[]	Access privileges; see <a href="#">Section 5.7</a> for details
reloptions text[]	Access-method-specific options, as “keyword=value” strings
relpartbound <code>pg_node_tree</code>	If table is a partition (see <code>relispartition</code> ), internal representation of the partition bound

Several of the Boolean flags in `pg_class` are maintained lazily: they are guaranteed to be true if that's the correct state, but may not be reset to false immediately when the condition is no longer true. For example, `relhasindex` is set by `CREATE INDEX`, but it is never cleared by `DROP INDEX`. Instead, `VACUUM` clears `relhasindex` if it finds the table has no indexes. This arrangement avoids race conditions and improves concurrency.

## 49.12. `pg_collation`

The catalog `pg_collation` describes the available collations, which are essentially mappings from an SQL name to operating system locale categories. See [Section 22.2](#) for more information.

**Table 49.12. `pg_collation` Columns**

Column Type	Description
<code>oid oid</code>	Row identifier
<code>collname name</code>	Collation name (unique per namespace and encoding)
<code>collnamespace oid (references <code>pg_namespace</code> .oid)</code>	The OID of the namespace that contains this collation
<code>collowner oid (references <code>pg_authid</code> .oid)</code>	Owner of the collation
<code>collprovider char</code>	Provider of the collation: <code>d</code> = database default, <code>c</code> = libc, <code>i</code> = icu
<code>collisdeterministic bool</code>	Is the collation deterministic?
<code>collencoding int4</code>	Encoding in which the collation is applicable, or -1 if it works for any encoding
<code>collcollate name</code>	<code>LC_COLLATE</code> for this collation object
<code>collctype name</code>	<code>LC_CTYPE</code> for this collation object
<code>collversion text</code>	Provider-specific version of the collation. This is recorded when the collation is created and then checked when it is used, to detect changes in the collation definition that could lead to data corruption.

Note that the unique key on this catalog is `(collname, collencoding, collnamespace)` not just `(collname, collnamespace)`. Postgres Pro generally ignores all collations that do not have `collencoding` equal to either the current database's encoding or -1, and creation of new entries with the same name as an entry with `collencoding = -1` is forbidden. Therefore it is sufficient to use a qualified SQL name (`schema.name`) to identify a collation, even though this is not unique according to the catalog definition. The reason for defining the catalog this way is that `initdb` fills it in at cluster initialization time with entries for all locales available on the system, so it must be able to hold entries for all encodings that might ever be used in the cluster.

In the `template0` database, it could be useful to create collations whose encoding does not match the database encoding, since they could match the encodings of databases later cloned from `template0`. This would currently have to be done manually.

## 49.13. `pg_constraint`

The catalog `pg_constraint` stores check, primary key, unique, foreign key, and exclusion constraints on tables. (Column constraints are not treated specially. Every column constraint is equivalent to some table constraint.) Not-null constraints are represented in the `pg_attribute` catalog, not here.

User-defined constraint triggers (created with `CREATE CONSTRAINT TRIGGER`) also give rise to an entry in this table.

Check constraints on domains are stored here, too.

**Table 49.13. `pg_constraint` Columns**

Column Type	Description
<code>oid oid</code>	Row identifier
<code>conname name</code>	Constraint name (not necessarily unique!)
<code>connamespace oid (references <code>pg_namespace</code> .oid)</code>	The OID of the namespace that contains this constraint
<code>contype char</code>	<code>c</code> = check constraint, <code>f</code> = foreign key constraint, <code>p</code> = primary key constraint, <code>u</code> = unique constraint, <code>t</code> = constraint trigger, <code>x</code> = exclusion constraint
<code>condeferrable bool</code>	Is the constraint deferrable?
<code>condeferred bool</code>	Is the constraint deferred by default?
<code>convalidated bool</code>	Has the constraint been validated? Currently, can only be false for foreign keys and CHECK constraints
<code>conrelid oid (references <code>pg_class</code> .oid)</code>	The table this constraint is on; 0 if not a table constraint
<code>contypid oid (references <code>pg_type</code> .oid)</code>	The domain this constraint is on; 0 if not a domain constraint
<code>conindid oid (references <code>pg_class</code> .oid)</code>	The index supporting this constraint, if it's a unique, primary key, foreign key, or exclusion constraint; else 0
<code>conparentid oid (references <code>pg_constraint</code> .oid)</code>	The corresponding constraint in the parent partitioned table, if this is a constraint in a partition; else 0
<code>confrelid oid (references <code>pg_class</code> .oid)</code>	If a foreign key, the referenced table; else 0
<code>confupdtype char</code>	Foreign key update action code: <code>a</code> = no action, <code>r</code> = restrict, <code>c</code> = cascade, <code>n</code> = set null, <code>d</code> = set default
<code>confdeltype char</code>	Foreign key deletion action code: <code>a</code> = no action, <code>r</code> = restrict, <code>c</code> = cascade, <code>n</code> = set null, <code>d</code> = set default
<code>confmatchtype char</code>	Foreign key match type: <code>f</code> = full, <code>p</code> = partial, <code>s</code> = simple
<code>conislocal bool</code>	This constraint is defined locally for the relation. Note that a constraint can be locally defined and inherited simultaneously.

Column Type	Description
<code>coninhcount int4</code>	The number of direct inheritance ancestors this constraint has. A constraint with a nonzero number of ancestors cannot be dropped nor renamed.
<code>connoinherit bool</code>	This constraint is defined locally for the relation. It is a non-inheritable constraint.
<code>conkey int2[] (references <a href="#">pg_attribute</a> .attnum)</code>	If a table constraint (including foreign keys, but not constraint triggers), list of the constrained columns
<code>confkey int2[] (references <a href="#">pg_attribute</a> .attnum)</code>	If a foreign key, list of the referenced columns
<code>conpfeqop oid[] (references <a href="#">pg_operator</a> .oid)</code>	If a foreign key, list of the equality operators for PK = FK comparisons
<code>conppeqop oid[] (references <a href="#">pg_operator</a> .oid)</code>	If a foreign key, list of the equality operators for PK = PK comparisons
<code>conffeqop oid[] (references <a href="#">pg_operator</a> .oid)</code>	If a foreign key, list of the equality operators for FK = FK comparisons
<code>conexcllop oid[] (references <a href="#">pg_operator</a> .oid)</code>	If an exclusion constraint, list of the per-column exclusion operators
<code>conbin pg_node_tree</code>	If a check constraint, an internal representation of the expression. (It's recommended to use <code>pg_get_constraintdef()</code> to extract the definition of a check constraint.)

In the case of an exclusion constraint, `conkey` is only useful for constraint elements that are simple column references. For other cases, a zero appears in `conkey` and the associated index must be consulted to discover the expression that is constrained. (`conkey` thus has the same contents as `pg_index.indkey` for the index.)

### Note

`pg_class.relchecks` needs to agree with the number of check-constraint entries found in this table for each relation.

## 49.14. pg\_conversion

The catalog `pg_conversion` describes encoding conversion functions. See [CREATE CONVERSION](#) for more information.

**Table 49.14. pg\_conversion Columns**

Column Type	Description
<code>oid oid</code>	Row identifier
<code>conname name</code>	Conversion name (unique within a namespace)
<code>connamespace oid (references <a href="#">pg_namespace</a> .oid)</code>	The OID of the namespace that contains this conversion
<code>conowner oid (references <a href="#">pg_authid</a> .oid)</code>	Owner of the conversion
<code>confencoding int4</code>	

Column Type	Description
	Source encoding ID
contencoding int4	Destination encoding ID
conproc regproc (references <code>pg_proc</code> .oid)	Conversion function
condefault bool	True if this is the default conversion

## 49.15. pg\_database

The catalog `pg_database` stores information about the available databases. Databases are created with the [CREATE DATABASE](#) command. Consult [Chapter 21](#) for details about the meaning of some of the parameters.

Unlike most system catalogs, `pg_database` is shared across all databases of a cluster: there is only one copy of `pg_database` per cluster, not one per database.

**Table 49.15. pg\_database Columns**

Column Type	Description
oid oid	Row identifier
datname name	Database name
datdba oid (references <code>pg_authid</code> .oid)	Owner of the database, usually the user who created it
encoding int4	Character encoding for this database ( <code>pg_encoding_to_char()</code> can translate this number to the encoding name)
datcollate name	LC_COLLATE for this database
datctype name	LC_CTYPE for this database
datistemplate bool	If true, then this database can be cloned by any user with <code>CREATEDB</code> privileges; if false, then only superusers or the owner of the database can clone it.
datallowconn bool	If false then no one can connect to this database. This is used to protect the <code>template0</code> database from being altered.
datconlimit int4	Sets maximum number of concurrent connections that can be made to this database. -1 means no limit.
datlastsysoid oid	Last system OID in the database; useful particularly to <code>pg_dump</code>
datfrozenxid xid	All transaction IDs before this one have been replaced with a permanent (“frozen”) transaction ID in this database. This is used to track whether the database needs to be vacuumed in order to prevent transaction ID wraparound or to allow <code>pg_xact</code> to be shrunk. It is the minimum of the per-table <code>pg_class</code> .relfrozenxid values.

Column Type	Description
<code>datminmxid xid</code>	All multixact IDs before this one have been replaced with a transaction ID in this database. This is used to track whether the database needs to be vacuumed in order to prevent multixact ID wraparound or to allow <code>pg_multixact</code> to be shrunk. It is the minimum of the per-table <code>pg_class .relminmxid</code> values.
<code>dattablespace oid (references <a href="#">pg_tablespace</a> .oid)</code>	The default tablespace for the database. Within this database, all tables for which <code>pg_class .reltablespace</code> is zero will be stored in this tablespace; in particular, all the non-shared system catalogs will be there.
<code>datacl aclitem[]</code>	Access privileges; see <a href="#">Section 5.7</a> for details

## 49.16. `pg_db_role_setting`

The catalog `pg_db_role_setting` records the default values that have been set for run-time configuration variables, for each role and database combination.

Unlike most system catalogs, `pg_db_role_setting` is shared across all databases of a cluster: there is only one copy of `pg_db_role_setting` per cluster, not one per database.

**Table 49.16. `pg_db_role_setting` Columns**

Column Type	Description
<code>setdatabase oid (references <a href="#">pg_database</a> .oid)</code>	The OID of the database the setting is applicable to, or zero if not database-specific
<code>setrole oid (references <a href="#">pg_authid</a> .oid)</code>	The OID of the role the setting is applicable to, or zero if not role-specific
<code>setconfig text[]</code>	Defaults for run-time configuration variables

## 49.17. `pg_default_acl`

The catalog `pg_default_acl` stores initial privileges to be assigned to newly created objects.

**Table 49.17. `pg_default_acl` Columns**

Column Type	Description
<code>oid oid</code>	Row identifier
<code>defaclrole oid (references <a href="#">pg_authid</a> .oid)</code>	The OID of the role associated with this entry
<code>defaclnamespace oid (references <a href="#">pg_namespace</a> .oid)</code>	The OID of the namespace associated with this entry, or 0 if none
<code>defaclobjtype char</code>	Type of object this entry is for: <code>r</code> = relation (table, view), <code>s</code> = sequence, <code>f</code> = function, <code>T</code> = type, <code>n</code> = schema
<code>defaclacl aclitem[]</code>	Access privileges that this type of object should have on creation

A `pg_default_acl` entry shows the initial privileges to be assigned to an object belonging to the indicated user. There are currently two types of entry: “global” entries with `defaclnamespace` = 0, and “per-

schema” entries that reference a particular schema. If a global entry is present then it *overrides* the normal hard-wired default privileges for the object type. A per-schema entry, if present, represents privileges to be *added* to the global or hard-wired default privileges.

Note that when an ACL entry in another catalog is null, it is taken to represent the hard-wired default privileges for its object, *not* whatever might be in `pg_default_acl` at the moment. `pg_default_acl` is only consulted during object creation.

## 49.18. `pg_depend`

The catalog `pg_depend` records the dependency relationships between database objects. This information allows `DROP` commands to find which other objects must be dropped by `DROP CASCADE` or prevent dropping in the `DROP RESTRICT` case.

See also `pg_shdepend`, which performs a similar function for dependencies involving objects that are shared across a database cluster.

**Table 49.18. `pg_depend` Columns**

Column Type	Description
<code>classid oid</code> (references <code>pg_class .oid</code> )	The OID of the system catalog the dependent object is in
<code>objid oid</code> (references any OID column)	The OID of the specific dependent object
<code>objsubid int4</code>	For a table column, this is the column number (the <code>objid</code> and <code>classid</code> refer to the table itself). For all other object types, this column is zero.
<code>refclassid oid</code> (references <code>pg_class .oid</code> )	The OID of the system catalog the referenced object is in
<code>refobjid oid</code> (references any OID column)	The OID of the specific referenced object
<code>refobjsubid int4</code>	For a table column, this is the column number (the <code>refobjid</code> and <code>refclassid</code> refer to the table itself). For all other object types, this column is zero.
<code>deptype char</code>	A code defining the specific semantics of this dependency relationship; see text

In all cases, a `pg_depend` entry indicates that the referenced object cannot be dropped without also dropping the dependent object. However, there are several subflavors identified by `deptype`:

`DEPENDENCY_NORMAL` (n)

A normal relationship between separately-created objects. The dependent object can be dropped without affecting the referenced object. The referenced object can only be dropped by specifying `CASCADE`, in which case the dependent object is dropped, too. Example: a table column has a normal dependency on its data type.

`DEPENDENCY_AUTO` (a)

The dependent object can be dropped separately from the referenced object, and should be automatically dropped (regardless of `RESTRICT` or `CASCADE` mode) if the referenced object is dropped. Example: a named constraint on a table is made auto-dependent on the table, so that it will go away if the table is dropped.

`DEPENDENCY_INTERNAL` (i)

The dependent object was created as part of creation of the referenced object, and is really just a part of its internal implementation. A direct `DROP` of the dependent object will be disallowed outright

(we'll tell the user to issue a `DROP` against the referenced object, instead). A `DROP` of the referenced object will result in automatically dropping the dependent object whether `CASCADE` is specified or not. If the dependent object has to be dropped due to a dependency on some other object being removed, its drop is converted to a drop of the referenced object, so that `NORMAL` and `AUTO` dependencies of the dependent object behave much like they were dependencies of the referenced object. Example: a view's `ON SELECT` rule is made internally dependent on the view, preventing it from being dropped while the view remains. Dependencies of the rule (such as tables it refers to) act as if they were dependencies of the view.

`DEPENDENCY_PARTITION_PRI` (P)

`DEPENDENCY_PARTITION_SEC` (S)

The dependent object was created as part of creation of the referenced object, and is really just a part of its internal implementation; however, unlike `INTERNAL`, there is more than one such referenced object. The dependent object must not be dropped unless at least one of these referenced objects is dropped; if any one is, the dependent object should be dropped whether or not `CASCADE` is specified. Also unlike `INTERNAL`, a drop of some other object that the dependent object depends on does not result in automatic deletion of any partition-referenced object. Hence, if the drop does not cascade to at least one of these objects via some other path, it will be refused. (In most cases, the dependent object shares all its non-partition dependencies with at least one partition-referenced object, so that this restriction does not result in blocking any cascaded delete.) Primary and secondary partition dependencies behave identically except that the primary dependency is preferred for use in error messages; hence, a partition-dependent object should have one primary partition dependency and one or more secondary partition dependencies. Note that partition dependencies are made in addition to, not instead of, any dependencies the object would normally have. This simplifies `ATTACH/DETACH PARTITION` operations: the partition dependencies need only be added or removed. Example: a child partitioned index is made partition-dependent on both the partition table it is on and the parent partitioned index, so that it goes away if either of those is dropped, but not otherwise. The dependency on the parent index is primary, so that if the user tries to drop the child partitioned index, the error message will suggest dropping the parent index instead (not the table).

`DEPENDENCY_EXTENSION` (e)

The dependent object is a member of the *extension* that is the referenced object (see [pg\\_extension](#)). The dependent object can be dropped only via `DROP EXTENSION` on the referenced object. Functionally this dependency type acts the same as an `INTERNAL` dependency, but it's kept separate for clarity and to simplify `pg_dump`.

`DEPENDENCY_AUTO_EXTENSION` (x)

The dependent object is not a member of the extension that is the referenced object (and so it should not be ignored by `pg_dump`), but it cannot function without the extension and should be auto-dropped if the extension is. The dependent object may be dropped on its own as well. Functionally this dependency type acts the same as an `AUTO` dependency, but it's kept separate for clarity and to simplify `pg_dump`.

`DEPENDENCY_PIN` (p)

There is no dependent object; this type of entry is a signal that the system itself depends on the referenced object, and so that object must never be deleted. Entries of this type are created only by `initdb`. The columns for the dependent object contain zeroes.

Other dependency flavors might be needed in future.

Note that it's quite possible for two objects to be linked by more than one `pg_depend` entry. For example, a child partitioned index would have both a partition-type dependency on its associated partition table, and an auto dependency on each column of that table that it indexes. This sort of situation expresses the union of multiple dependency semantics. A dependent object can be dropped without `CASCADE` if any of its dependencies satisfies its condition for automatic dropping. Conversely, all the dependencies' restrictions about which objects must be dropped together must be satisfied.

## 49.19. pg\_description

The catalog `pg_description` stores optional descriptions (comments) for each database object. Descriptions can be manipulated with the `COMMENT` command and viewed with `psql`'s `\d` commands. Descriptions of many built-in system objects are provided in the initial contents of `pg_description`.

See also `pg_shdescription`, which performs a similar function for descriptions involving objects that are shared across a database cluster.

**Table 49.19. pg\_description Columns**

Column Type	Description
<code>objoid oid</code> (references any OID column)	The OID of the object this description pertains to
<code>classoid oid</code> (references <code>pg_class</code> .oid)	The OID of the system catalog this object appears in
<code>objsubid int4</code>	For a comment on a table column, this is the column number (the <code>objoid</code> and <code>classoid</code> refer to the table itself). For all other object types, this column is zero.
<code>description text</code>	Arbitrary text that serves as the description of this object

## 49.20. pg\_enum

The `pg_enum` catalog contains entries showing the values and labels for each enum type. The internal representation of a given enum value is actually the OID of its associated row in `pg_enum`.

**Table 49.20. pg\_enum Columns**

Column Type	Description
<code>oid oid</code>	Row identifier
<code>enumtypeid oid</code> (references <code>pg_type</code> .oid)	The OID of the <code>pg_type</code> entry owning this enum value
<code>enumsortorder float4</code>	The sort position of this enum value within its enum type
<code>enumlabel name</code>	The textual label for this enum value

The OIDs for `pg_enum` rows follow a special rule: even-numbered OIDs are guaranteed to be ordered in the same way as the sort ordering of their enum type. That is, if two even OIDs belong to the same enum type, the smaller OID must have the smaller `enumsortorder` value. Odd-numbered OID values need bear no relationship to the sort order. This rule allows the enum comparison routines to avoid catalog lookups in many common cases. The routines that create and alter enum types attempt to assign even OIDs to enum values whenever possible.

When an enum type is created, its members are assigned sort-order positions  $1..n$ . But members added later might be given negative or fractional values of `enumsortorder`. The only requirement on these values is that they be correctly ordered and unique within each enum type.

## 49.21. pg\_event\_trigger

The catalog `pg_event_trigger` stores event triggers. See [Chapter 37](#) for more information.

**Table 49.21. pg\_event\_trigger Columns**

Column Type	Description
oid oid	Row identifier
evtname name	Trigger name (must be unique)
evtevent name	Identifies the event for which this trigger fires
evtowner oid (references <a href="#">pg_authid</a> .oid)	Owner of the event trigger
evtfoid oid (references <a href="#">pg_proc</a> .oid)	The function to be called
evtenabled char	Controls in which <a href="#">session_replication_role</a> modes the event trigger fires. O = trigger fires in “origin” and “local” modes, D = trigger is disabled, R = trigger fires in “replica” mode, A = trigger fires always.
evttags text []	Command tags for which this trigger will fire. If NULL, the firing of this trigger is not restricted on the basis of the command tag.

## 49.22. pg\_extension

The catalog `pg_extension` stores information about the installed extensions. See [Section 35.17](#) for details about extensions.

**Table 49.22. pg\_extension Columns**

Column Type	Description
oid oid	Row identifier
extname name	Name of the extension
extowner oid (references <a href="#">pg_authid</a> .oid)	Owner of the extension
extnamespace oid (references <a href="#">pg_namespace</a> .oid)	Schema containing the extension's exported objects
extrelocatable bool	True if extension can be relocated to another schema
extversion text	Version name for the extension
extconfig oid [] (references <a href="#">pg_class</a> .oid)	Array of <code>regclass</code> OIDs for the extension's configuration table(s), or NULL if none
extcondition text []	Array of WHERE-clause filter conditions for the extension's configuration table(s), or NULL if none

Note that unlike most catalogs with a “namespace” column, `extnamespace` is not meant to imply that the extension belongs to that schema. Extension names are never schema-qualified. Rather, `extnamespace` indicates the schema that contains most or all of the extension's objects. If `extrelocatable` is true, then this schema must in fact contain all schema-qualifiable objects belonging to the extension.

## 49.23. pg\_foreign\_data\_wrapper

The catalog `pg_foreign_data_wrapper` stores foreign-data wrapper definitions. A foreign-data wrapper is the mechanism by which external data, residing on foreign servers, is accessed.

**Table 49.23. pg\_foreign\_data\_wrapper Columns**

Column Type	Description
oid oid	Row identifier
fdwname name	Name of the foreign-data wrapper
fdwowner oid (references <code>pg_authid</code> .oid)	Owner of the foreign-data wrapper
fdwhandler oid (references <code>pg_proc</code> .oid)	References a handler function that is responsible for supplying execution routines for the foreign-data wrapper. Zero if no handler is provided
fdwvalidator oid (references <code>pg_proc</code> .oid)	References a validator function that is responsible for checking the validity of the options given to the foreign-data wrapper, as well as options for foreign servers and user mappings using the foreign-data wrapper. Zero if no validator is provided
fdwacl aclitem[]	Access privileges; see <a href="#">Section 5.7</a> for details
fdwoptions text[]	Foreign-data wrapper specific options, as “keyword=value” strings

## 49.24. pg\_foreign\_server

The catalog `pg_foreign_server` stores foreign server definitions. A foreign server describes a source of external data, such as a remote server. Foreign servers are accessed via foreign-data wrappers.

**Table 49.24. pg\_foreign\_server Columns**

Column Type	Description
oid oid	Row identifier
srvname name	Name of the foreign server
srvowner oid (references <code>pg_authid</code> .oid)	Owner of the foreign server
srvfdw oid (references <code>pg_foreign_data_wrapper</code> .oid)	OID of the foreign-data wrapper of this foreign server
srvtype text	Type of the server (optional)
srvversion text	Version of the server (optional)
srvacl aclitem[]	Access privileges; see <a href="#">Section 5.7</a> for details
srvoptions text[]	Foreign server specific options, as “keyword=value” strings

## 49.25. pg\_foreign\_table

The catalog `pg_foreign_table` contains auxiliary information about foreign tables. A foreign table is primarily represented by a `pg_class` entry, just like a regular table. Its `pg_foreign_table` entry contains the information that is pertinent only to foreign tables and not any other kind of relation.

**Table 49.25. pg\_foreign\_table Columns**

Column Type	Description
<code>ftrelid oid</code> (references <code>pg_class .oid</code> )	OID of the <code>pg_class</code> entry for this foreign table
<code>ftserver oid</code> (references <code>pg_foreign_server .oid</code> )	OID of the foreign server for this foreign table
<code>ftoptions text[]</code>	Foreign table options, as “keyword=value” strings

## 49.26. pg\_index

The catalog `pg_index` contains part of the information about indexes. The rest is mostly in `pg_class`.

**Table 49.26. pg\_index Columns**

Column Type	Description
<code>indexrelid oid</code> (references <code>pg_class .oid</code> )	The OID of the <code>pg_class</code> entry for this index
<code>indrelid oid</code> (references <code>pg_class .oid</code> )	The OID of the <code>pg_class</code> entry for the table this index is for
<code>indnatts int2</code>	The total number of columns in the index (duplicates <code>pg_class.relnatts</code> ); this number includes both key and included attributes
<code>indnkeyatts int2</code>	The number of <i>key columns</i> in the index, not counting any <i>included columns</i> , which are merely stored and do not participate in the index semantics
<code>indisunique bool</code>	If true, this is a unique index
<code>indisprimary bool</code>	If true, this index represents the primary key of the table ( <code>indisunique</code> should always be true when this is true)
<code>indisexclusion bool</code>	If true, this index supports an exclusion constraint
<code>indimmediate bool</code>	If true, the uniqueness check is enforced immediately on insertion (irrelevant if <code>indisunique</code> is not true)
<code>indisclustered bool</code>	If true, the table was last clustered on this index
<code>indisvalid bool</code>	If true, the index is currently valid for queries. False means the index is possibly incomplete: it must still be modified by <code>INSERT/UPDATE</code> operations, but it cannot safely be used for queries. If it is unique, the uniqueness property is not guaranteed true either.
<code>indcheckxmin bool</code>	

Column Type	Description
	If true, queries must not use the index until the <code>xmin</code> of this <code>pg_index</code> row is below their <code>TransactionXmin</code> event horizon, because the table may contain broken HOT chains with incompatible rows that they can see
<code>indisready</code> bool	If true, the index is currently ready for inserts. False means the index must be ignored by <code>INSERT/UPDATE</code> operations.
<code>indislive</code> bool	If false, the index is in process of being dropped, and should be ignored for all purposes (including HOT-safety decisions)
<code>indisreplident</code> bool	If true this index has been chosen as “replica identity” using <code>ALTER TABLE ... REPLICA IDENTITY USING INDEX ...</code>
<code>indkey</code> int2vector (references <code>pg_attribute</code> .attnum)	This is an array of <code>indnatts</code> values that indicate which table columns this index indexes. For example a value of <code>1 3</code> would mean that the first and the third table columns make up the index entries. Key columns come before non-key (included) columns. A zero in this array indicates that the corresponding index attribute is an expression over the table columns, rather than a simple column reference.
<code>indcollation</code> oidvector (references <code>pg_collation</code> .oid)	For each column in the index key ( <code>indnkeyatts</code> values), this contains the OID of the collation to use for the index, or zero if the column is not of a collatable data type.
<code>indclass</code> oidvector (references <code>pg_opclass</code> .oid)	For each column in the index key ( <code>indnkeyatts</code> values), this contains the OID of the operator class to use. See <code>pg_opclass</code> for details.
<code>indoption</code> int2vector	This is an array of <code>indnkeyatts</code> values that store per-column flag bits. The meaning of the bits is defined by the index's access method.
<code>indexprs</code> pg_node_tree	Expression trees (in <code>nodeToString()</code> representation) for index attributes that are not simple column references. This is a list with one element for each zero entry in <code>indkey</code> . Null if all index attributes are simple references.
<code>indpred</code> pg_node_tree	Expression tree (in <code>nodeToString()</code> representation) for partial index predicate. Null if not a partial index.

## 49.27. pg\_inherits

The catalog `pg_inherits` records information about table and index inheritance hierarchies. There is one entry for each direct parent-child table or index relationship in the database. (Indirect inheritance can be determined by following chains of entries.)

**Table 49.27. pg\_inherits Columns**

Column Type	Description
<code>inhrelid</code> oid (references <code>pg_class</code> .oid)	The OID of the child table or index
<code>inhparent</code> oid (references <code>pg_class</code> .oid)	The OID of the parent table or index
<code>inhseqno</code> int4	

Column Type	Description
	If there is more than one direct parent for a child table (multiple inheritance), this number tells the order in which the inherited columns are to be arranged. The count starts at 1. Indexes cannot have multiple inheritance, since they can only inherit when using declarative partitioning.

## 49.28. pg\_init\_privs

The catalog `pg_init_privs` records information about the initial privileges of objects in the system. There is one entry for each object in the database which has a non-default (non-NULL) initial set of privileges.

Objects can have initial privileges either by having those privileges set when the system is initialized (by `initdb`) or when the object is created during a `CREATE EXTENSION` and the extension script sets initial privileges using the `GRANT` system. Note that the system will automatically handle recording of the privileges during the extension script and that extension authors need only use the `GRANT` and `REVOKE` statements in their script to have the privileges recorded. The `privtype` column indicates if the initial privilege was set by `initdb` or during a `CREATE EXTENSION` command.

Objects which have initial privileges set by `initdb` will have entries where `privtype` is 'i', while objects which have initial privileges set by `CREATE EXTENSION` will have entries where `privtype` is 'e'.

**Table 49.28. pg\_init\_privs Columns**

Column Type	Description
<code>objoid oid</code> (references any OID column)	The OID of the specific object
<code>classoid oid</code> (references <code>pg_class .oid</code> )	The OID of the system catalog the object is in
<code>objsubid int4</code>	For a table column, this is the column number (the <code>objoid</code> and <code>classoid</code> refer to the table itself). For all other object types, this column is zero.
<code>privtype char</code>	A code defining the type of initial privilege of this object; see text
<code>initprivs aclitem[]</code>	The initial access privileges; see <a href="#">Section 5.7</a> for details

## 49.29. pg\_language

The catalog `pg_language` registers languages in which you can write functions or stored procedures. See [CREATE LANGUAGE](#) and [Chapter 39](#) for more information about language handlers.

**Table 49.29. pg\_language Columns**

Column Type	Description
<code>oid oid</code>	Row identifier
<code>lanname name</code>	Name of the language
<code>lanowner oid</code> (references <code>pg_authid .oid</code> )	Owner of the language
<code>lanispl bool</code>	

Column Type	Description
	This is false for internal languages (such as SQL) and true for user-defined languages. Currently, <code>pg_dump</code> still uses this to determine which languages need to be dumped, but this might be replaced by a different mechanism in the future.
<code>lanpltrusted</code> bool	True if this is a trusted language, which means that it is believed not to grant access to anything outside the normal SQL execution environment. Only superusers can create functions in untrusted languages.
<code>lanplcallfoid</code> oid (references <code>pg_proc</code> .oid)	For noninternal languages this references the language handler, which is a special function that is responsible for executing all functions that are written in the particular language
<code>laninline</code> oid (references <code>pg_proc</code> .oid)	This references a function that is responsible for executing “inline” anonymous code blocks ( <a href="#">DO blocks</a> ). Zero if inline blocks are not supported.
<code>lanvalidator</code> oid (references <code>pg_proc</code> .oid)	This references a language validator function that is responsible for checking the syntax and validity of new functions when they are created. Zero if no validator is provided.
<code>lanacl</code> aclitem[]	Access privileges; see <a href="#">Section 5.7</a> for details

## 49.30. `pg_largeobject`

The catalog `pg_largeobject` holds the data making up “large objects”. A large object is identified by an OID assigned when it is created. Each large object is broken into segments or “pages” small enough to be conveniently stored as rows in `pg_largeobject`. The amount of data per page is defined to be `LOBLKSIZE` (which is currently `BLCKSZ/4`, or typically 2 kB).

Prior to PostgreSQL 9.0, there was no permission structure associated with large objects. As a result, `pg_largeobject` was publicly readable and could be used to obtain the OIDs (and contents) of all large objects in the system. This is no longer the case; use `pg_largeobject_metadata` to obtain a list of large object OIDs.

**Table 49.30. `pg_largeobject` Columns**

Column Type	Description
<code>loid</code> oid (references <code>pg_largeobject_metadata</code> .oid)	Identifier of the large object that includes this page
<code>pageno</code> int4	Page number of this page within its large object (counting from zero)
<code>data</code> bytea	Actual data stored in the large object. This will never be more than <code>LOBLKSIZE</code> bytes and might be less.

Each row of `pg_largeobject` holds data for one page of a large object, beginning at byte offset (`pageno * LOBLKSIZE`) within the object. The implementation allows sparse storage: pages might be missing, and might be shorter than `LOBLKSIZE` bytes even if they are not the last page of the object. Missing regions within a large object read as zeroes.

## 49.31. `pg_largeobject_metadata`

The catalog `pg_largeobject_metadata` holds metadata associated with large objects. The actual large object data is stored in `pg_largeobject`.

**Table 49.31. pg\_largeobject\_metadata Columns**

Column Type	Description
oid oid	Row identifier
lomowner oid (references <a href="#">pg_authid</a> .oid)	Owner of the large object
lomacl aclitem[]	Access privileges; see <a href="#">Section 5.7</a> for details

## 49.32. pg\_namespace

The catalog `pg_namespace` stores namespaces. A namespace is the structure underlying SQL schemas: each namespace can have a separate collection of relations, types, etc. without name conflicts.

**Table 49.32. pg\_namespace Columns**

Column Type	Description
oid oid	Row identifier
nspname name	Name of the namespace
nspowner oid (references <a href="#">pg_authid</a> .oid)	Owner of the namespace
nspacl aclitem[]	Access privileges; see <a href="#">Section 5.7</a> for details

## 49.33. pg\_opclass

The catalog `pg_opclass` defines index access method operator classes. Each operator class defines semantics for index columns of a particular data type and a particular index access method. An operator class essentially specifies that a particular operator family is applicable to a particular indexable column data type. The set of operators from the family that are actually usable with the indexed column are whichever ones accept the column's data type as their left-hand input.

Operator classes are described at length in [Section 35.16](#).

**Table 49.33. pg\_opclass Columns**

Column Type	Description
oid oid	Row identifier
opcmethod oid (references <a href="#">pg_am</a> .oid)	Index access method operator class is for
opcname name	Name of this operator class
opcnamespace oid (references <a href="#">pg_namespace</a> .oid)	Namespace of this operator class
opcowner oid (references <a href="#">pg_authid</a> .oid)	Owner of the operator class
opcfamily oid (references <a href="#">pg_opfamily</a> .oid)	

Column Type	Description
	Operator family containing the operator class
opcintype oid (references <a href="#">pg_type</a> .oid)	Data type that the operator class indexes
opcdefault bool	True if this operator class is the default for opcintype
opckeytype oid (references <a href="#">pg_type</a> .oid)	Type of data stored in index, or zero if same as opcintype

An operator class's `opcmethod` must match the `opfmethod` of its containing operator family. Also, there must be no more than one `pg_opclass` row having `opcdefault` true for any given combination of `opcmethod` and `opcintype`.

## 49.34. pg\_operator

The catalog `pg_operator` stores information about operators. See [CREATE OPERATOR](#) and [Section 35.14](#) for more information.

**Table 49.34. pg\_operator Columns**

Column Type	Description
oid oid	Row identifier
oprname name	Name of the operator
oprnamespace oid (references <a href="#">pg_namespace</a> .oid)	The OID of the namespace that contains this operator
oprowner oid (references <a href="#">pg_authid</a> .oid)	Owner of the operator
oprkind char	b = infix (“both”), l = prefix (“left”), r = postfix (“right”)
oprcanmerge bool	This operator supports merge joins
oprhash bool	This operator supports hash joins
oprleft oid (references <a href="#">pg_type</a> .oid)	Type of the left operand
oprright oid (references <a href="#">pg_type</a> .oid)	Type of the right operand
oprresult oid (references <a href="#">pg_type</a> .oid)	Type of the result
oprcom oid (references <a href="#">pg_operator</a> .oid)	Commutator of this operator, if any
oprnegate oid (references <a href="#">pg_operator</a> .oid)	Negator of this operator, if any
oprproc regproc (references <a href="#">pg_proc</a> .oid)	Function that implements this operator
oprrest regproc (references <a href="#">pg_proc</a> .oid)	Restriction selectivity estimation function for this operator

Column Type	Description
oprjoin regproc (references <a href="#">pg_proc</a> .oid)	Join selectivity estimation function for this operator

Unused columns contain zeroes. For example, `oprleft` is zero for a prefix operator.

## 49.35. `pg_opfamily`

The catalog `pg_opfamily` defines operator families. Each operator family is a collection of operators and associated support routines that implement the semantics specified for a particular index access method. Furthermore, the operators in a family are all “compatible”, in a way that is specified by the access method. The operator family concept allows cross-data-type operators to be used with indexes and to be reasoned about using knowledge of access method semantics.

Operator families are described at length in [Section 35.16](#).

**Table 49.35. `pg_opfamily` Columns**

Column Type	Description
oid oid	Row identifier
opfmethod oid (references <a href="#">pg_am</a> .oid)	Index access method operator family is for
opfname name	Name of this operator family
opfnamespace oid (references <a href="#">pg_namespace</a> .oid)	Namespace of this operator family
opfowner oid (references <a href="#">pg_authid</a> .oid)	Owner of the operator family

The majority of the information defining an operator family is not in its `pg_opfamily` row, but in the associated rows in [pg\\_amop](#), [pg\\_amproc](#), and [pg\\_opclass](#).

## 49.36. `pg_partitioned_table`

The catalog `pg_partitioned_table` stores information about how tables are partitioned.

**Table 49.36. `pg_partitioned_table` Columns**

Column Type	Description
partrelid oid (references <a href="#">pg_class</a> .oid)	The OID of the <code>pg_class</code> entry for this partitioned table
partstrat char	Partitioning strategy; h = hash partitioned table, l = list partitioned table, r = range partitioned table
partnatts int2	The number of columns in partition key
partdefid oid (references <a href="#">pg_class</a> .oid)	The OID of the <code>pg_class</code> entry for the default partition of this partitioned table, or zero if this partitioned table does not have a default partition.
partattrs int2vector (references <a href="#">pg_attribute</a> .attnum)	This is an array of <code>partnatts</code> values that indicate which table columns are part of the partition key. For example, a value of <code>1 3</code> would mean that the first and the third table

Column Type	Description
	columns make up the partition key. A zero in this array indicates that the corresponding partition key column is an expression, rather than a simple column reference.
partclass oidvector (references <a href="#">pg_opclass</a> .oid)	For each column in the partition key, this contains the OID of the operator class to use. See <a href="#">pg_opclass</a> for details.
partcollation oidvector (references <a href="#">pg_collation</a> .oid)	For each column in the partition key, this contains the OID of the collation to use for partitioning, or zero if the column is not of a collatable data type.
partexprs pg_node_tree	Expression trees (in <code>nodeToString()</code> representation) for partition key columns that are not simple column references. This is a list with one element for each zero entry in <code>partattrs</code> . Null if all partition key columns are simple references.

## 49.37. pg\_policy

The catalog `pg_policy` stores row level security policies for tables. A policy includes the kind of command that it applies to (possibly all commands), the roles that it applies to, the expression to be added as a security-barrier qualification to queries that include the table, and the expression to be added as a `WITH CHECK` option for queries that attempt to add new records to the table.

**Table 49.37. pg\_policy Columns**

Column Type	Description
oid oid	Row identifier
polname name	The name of the policy
polrelid oid (references <a href="#">pg_class</a> .oid)	The table to which the policy applies
polcmd char	The command type to which the policy is applied: <code>r</code> for <code>SELECT</code> , <code>a</code> for <code>INSERT</code> , <code>w</code> for <code>UPDATE</code> , <code>d</code> for <code>DELETE</code> , or <code>*</code> for all
polpermissive bool	Is the policy permissive or restrictive?
polroles oid[] (references <a href="#">pg_authid</a> .oid)	The roles to which the policy is applied
polqual pg_node_tree	The expression tree to be added to the security barrier qualifications for queries that use the table
polwithcheck pg_node_tree	The expression tree to be added to the <code>WITH CHECK</code> qualifications for queries that attempt to add rows to the table

### Note

Policies stored in `pg_policy` are applied only when `pg_class.relrowsecurity` is set for their table.

## 49.38. pg\_proc

The catalog `pg_proc` stores information about functions, procedures, aggregate functions, and window functions (collectively also known as routines). See [CREATE FUNCTION](#), [CREATE PROCEDURE](#), and [Section 35.3](#) for more information.

If `prokind` indicates that the entry is for an aggregate function, there should be a matching row in `pg_aggregate`.

**Table 49.38. `pg_proc` Columns**

Column Type	Description
<code>oid oid</code>	Row identifier
<code>proname name</code>	Name of the function
<code>pronamespace oid (references <code>pg_namespace</code> .oid)</code>	The OID of the namespace that contains this function
<code>proowner oid (references <code>pg_authid</code> .oid)</code>	Owner of the function
<code>prolang oid (references <code>pg_language</code> .oid)</code>	Implementation language or call interface of this function
<code>procost float4</code>	Estimated execution cost (in units of <code>cpu_operator_cost</code> ); if <code>proretset</code> , this is cost per row returned
<code>prorows float4</code>	Estimated number of result rows (zero if not <code>proretset</code> )
<code>provariadic oid (references <code>pg_type</code> .oid)</code>	Data type of the variadic array parameter's elements, or zero if the function does not have a variadic parameter
<code>prosupport regproc (references <code>pg_proc</code> .oid)</code>	Optional planner support function for this function (see <a href="#">Section 35.11</a> )
<code>prokind char</code>	<code>f</code> for a normal function, <code>p</code> for a procedure, <code>a</code> for an aggregate function, or <code>w</code> for a window function
<code>prosecdef bool</code>	Function is a security definer (i.e., a “setuid” function)
<code>proleakproof bool</code>	The function has no side effects. No information about the arguments is conveyed except via the return value. Any function that might throw an error depending on the values of its arguments is not leak-proof.
<code>proisstrict bool</code>	Function returns null if any call argument is null. In that case the function won't actually be called at all. Functions that are not “strict” must be prepared to handle null inputs.
<code>proretset bool</code>	Function returns a set (i.e., multiple values of the specified data type)
<code>provolatile char</code>	<code>provolatile</code> tells whether the function's result depends only on its input arguments, or is affected by outside factors. It is <code>i</code> for “immutable” functions, which always deliver the same result for the same inputs. It is <code>s</code> for “stable” functions, whose results (for fixed inputs) do not change within a scan. It is <code>v</code> for “volatile” functions, whose results might change at any time. (Use <code>v</code> also for functions with side-effects, so that calls to them cannot get optimized away.)
<code>proparallel char</code>	

Column Type	Description
	<code>proparallel</code> tells whether the function can be safely run in parallel mode. It is <code>s</code> for functions which are safe to run in parallel mode without restriction. It is <code>r</code> for functions which can be run in parallel mode, but their execution is restricted to the parallel group leader; parallel worker processes cannot invoke these functions. It is <code>u</code> for functions which are unsafe in parallel mode; the presence of such a function forces a serial execution plan.
<code>pronargs int2</code>	Number of input arguments
<code>pronargdefaults int2</code>	Number of arguments that have defaults
<code>prorettype oid</code> (references <code>pg_type .oid</code> )	Data type of the return value
<code>proargtypes oidvector</code> (references <code>pg_type .oid</code> )	An array of the data types of the function arguments. This includes only input arguments (including <code>INOUT</code> and <code>VARIADIC</code> arguments), and thus represents the call signature of the function.
<code>proallargtypes oid[]</code> (references <code>pg_type .oid</code> )	An array of the data types of the function arguments. This includes all arguments (including <code>OUT</code> and <code>INOUT</code> arguments); however, if all the arguments are <code>IN</code> arguments, this field will be null. Note that subscripting is 1-based, whereas for historical reasons <code>proargtypes</code> is subscripted from 0.
<code>proargmodes char[]</code>	An array of the modes of the function arguments, encoded as <code>i</code> for <code>IN</code> arguments, <code>o</code> for <code>OUT</code> arguments, <code>b</code> for <code>INOUT</code> arguments, <code>v</code> for <code>VARIADIC</code> arguments, <code>t</code> for <code>TABLE</code> arguments. If all the arguments are <code>IN</code> arguments, this field will be null. Note that subscripts correspond to positions of <code>proallargtypes</code> not <code>proargtypes</code> .
<code>proargnames text[]</code>	An array of the names of the function arguments. Arguments without a name are set to empty strings in the array. If none of the arguments have a name, this field will be null. Note that subscripts correspond to positions of <code>proallargtypes</code> not <code>proargtypes</code> .
<code>proargdefaults pg_node_tree</code>	Expression trees (in <code>nodeToString()</code> representation) for default values. This is a list with <code>pronargdefaults</code> elements, corresponding to the last $N$ input arguments (i.e., the last $N$ <code>proargtypes</code> positions). If none of the arguments have defaults, this field will be null.
<code>protrftypes oid[]</code> (references <code>pg_type .oid</code> )	An array of the argument/result data type(s) for which to apply transforms (from the function's <code>TRANSFORM</code> clause). Null if none.
<code>prosrc text</code>	This tells the function handler how to invoke the function. It might be the actual source code of the function for interpreted languages, a link symbol, a file name, or just about anything else, depending on the implementation language/call convention.
<code>probin text</code>	Additional information about how to invoke the function. Again, the interpretation is language-specific.
<code>proconfig text[]</code>	Function's local settings for run-time configuration variables
<code>proacl aclitem[]</code>	Access privileges; see <a href="#">Section 5.7</a> for details

For compiled functions, both built-in and dynamically loaded, `prosrc` contains the function's C-language name (link symbol). For all other currently-known language types, `prosrc` contains the function's source

text. `probin` is unused except for dynamically-loaded C functions, for which it gives the name of the shared library file containing the function.

## 49.39. `pg_publication`

The catalog `pg_publication` contains all publications created in the database. For more on publications see [Section 29.1](#).

**Table 49.39. `pg_publication` Columns**

Column Type	Description
oid oid	Row identifier
pubname name	Name of the publication
pubowner oid (references <code>pg_authid</code> .oid)	Owner of the publication
puballtables bool	If true, this publication automatically includes all tables in the database, including any that will be created in the future.
pubinsert bool	If true, INSERT operations are replicated for tables in the publication.
pubupdate bool	If true, UPDATE operations are replicated for tables in the publication.
pubdelete bool	If true, DELETE operations are replicated for tables in the publication.
pubtruncate bool	If true, TRUNCATE operations are replicated for tables in the publication.
pubviaroot bool	If true, operations on a leaf partition are replicated using the identity and schema of its topmost partitioned ancestor mentioned in the publication instead of its own.

## 49.40. `pg_publication_rel`

The catalog `pg_publication_rel` contains the mapping between relations and publications in the database. This is a many-to-many mapping. See also [Section 49.78](#) for a more user-friendly view of this information.

**Table 49.40. `pg_publication_rel` Columns**

Column Type	Description
oid oid	Row identifier
prpubid oid (references <code>pg_publication</code> .oid)	Reference to publication
prrelid oid (references <code>pg_class</code> .oid)	Reference to relation

## 49.41. `pg_range`

The catalog `pg_range` stores information about range types. This is in addition to the types' entries in `pg_type`.

**Table 49.41. pg\_range Columns**

Column Type	Description
rngtypeid oid (references <a href="#">pg_type</a> .oid)	OID of the range type
rngsubtype oid (references <a href="#">pg_type</a> .oid)	OID of the element type (subtype) of this range type
rngcollation oid (references <a href="#">pg_collation</a> .oid)	OID of the collation used for range comparisons, or 0 if none
rngsubopc oid (references <a href="#">pg_opclass</a> .oid)	OID of the subtype's operator class used for range comparisons
rngcanonical regproc (references <a href="#">pg_proc</a> .oid)	OID of the function to convert a range value into canonical form, or 0 if none
rngsubdiff regproc (references <a href="#">pg_proc</a> .oid)	OID of the function to return the difference between two element values as double precision, or 0 if none

`rngsubopc` (plus `rngcollation`, if the element type is collatable) determines the sort ordering used by the range type. `rngcanonical` is used when the element type is discrete. `rngsubdiff` is optional but should be supplied to improve performance of GiST indexes on the range type.

## 49.42. pg\_replication\_origin

The `pg_replication_origin` catalog contains all replication origins created. For more on replication origins see [Chapter 47](#).

Unlike most system catalogs, `pg_replication_origin` is shared across all databases of a cluster: there is only one copy of `pg_replication_origin` per cluster, not one per database.

**Table 49.42. pg\_replication\_origin Columns**

Column Type	Description
roident oid	A unique, cluster-wide identifier for the replication origin. Should never leave the system.
roname text	The external, user defined, name of a replication origin.

## 49.43. pg\_rewrite

The catalog `pg_rewrite` stores rewrite rules for tables and views.

**Table 49.43. pg\_rewrite Columns**

Column Type	Description
oid oid	Row identifier
rulename name	Rule name
ev_class oid (references <a href="#">pg_class</a> .oid)	The table this rule is for
ev_type char	

Column Type	Description
	Event type that the rule is for: 1 = SELECT, 2 = UPDATE, 3 = INSERT, 4 = DELETE
ev_enabled char	Controls in which <a href="#">session_replication_role</a> modes the rule fires. O = rule fires in “origin” and “local” modes, D = rule is disabled, R = rule fires in “replica” mode, A = rule fires always.
is_instead bool	True if the rule is an INSTEAD rule
ev_qual pg_node_tree	Expression tree (in the form of a <code>nodeToString()</code> representation) for the rule's qualifying condition
ev_action pg_node_tree	Query tree (in the form of a <code>nodeToString()</code> representation) for the rule's action

### Note

`pg_class.relhasrules` must be true if a table has any rules in this catalog.

## 49.44. pg\_seclabel

The catalog `pg_seclabel` stores security labels on database objects. Security labels can be manipulated with the [SECURITY LABEL](#) command. For an easier way to view security labels, see [Section 49.83](#).

See also [pg\\_shseclabel](#), which performs a similar function for security labels of database objects that are shared across a database cluster.

**Table 49.44. pg\_seclabel Columns**

Column Type	Description
objoid oid (references any OID column)	The OID of the object this security label pertains to
classoid oid (references <a href="#">pg_class</a> .oid)	The OID of the system catalog this object appears in
objsubid int4	For a security label on a table column, this is the column number (the <code>objoid</code> and <code>classoid</code> refer to the table itself). For all other object types, this column is zero.
provider text	The label provider associated with this label.
label text	The security label applied to this object.

## 49.45. pg\_sequence

The catalog `pg_sequence` contains information about sequences. Some of the information about sequences, such as the name and the schema, is in `pg_class`.

**Table 49.45. pg\_sequence Columns**

Column Type	Description
seqrelid oid (references <a href="#">pg_class</a> .oid)	

Column Type	Description
	The OID of the <code>pg_class</code> entry for this sequence
<code>seqtypeid oid</code> (references <code>pg_type .oid</code> )	Data type of the sequence
<code>seqstart int8</code>	Start value of the sequence
<code>seqincrement int8</code>	Increment value of the sequence
<code>seqmax int8</code>	Maximum value of the sequence
<code>seqmin int8</code>	Minimum value of the sequence
<code>seqcache int8</code>	Cache size of the sequence
<code>seqcycle bool</code>	Whether the sequence cycles

## 49.46. `pg_shdepend`

The catalog `pg_shdepend` records the dependency relationships between database objects and shared objects, such as roles. This information allows Postgres Pro to ensure that those objects are unreferenced before attempting to delete them.

See also `pg_depend`, which performs a similar function for dependencies involving objects within a single database.

Unlike most system catalogs, `pg_shdepend` is shared across all databases of a cluster: there is only one copy of `pg_shdepend` per cluster, not one per database.

**Table 49.46. `pg_shdepend` Columns**

Column Type	Description
<code>dbid oid</code> (references <code>pg_database .oid</code> )	The OID of the database the dependent object is in, or zero for a shared object
<code>classid oid</code> (references <code>pg_class .oid</code> )	The OID of the system catalog the dependent object is in
<code>objid oid</code> (references any OID column)	The OID of the specific dependent object
<code>objsubid int4</code>	For a table column, this is the column number (the <code>objid</code> and <code>classid</code> refer to the table itself). For all other object types, this column is zero.
<code>refclassid oid</code> (references <code>pg_class .oid</code> )	The OID of the system catalog the referenced object is in (must be a shared catalog)
<code>refobjid oid</code> (references any OID column)	The OID of the specific referenced object
<code>deptype char</code>	A code defining the specific semantics of this dependency relationship; see text

In all cases, a `pg_shdepend` entry indicates that the referenced object cannot be dropped without also dropping the dependent object. However, there are several subflavors identified by `deptype`:

SHARED\_DEPENDENCY\_OWNER (o)

The referenced object (which must be a role) is the owner of the dependent object.

SHARED\_DEPENDENCY\_ACL (a)

The referenced object (which must be a role) is mentioned in the ACL (access control list, i.e., privileges list) of the dependent object. (A `SHARED_DEPENDENCY_ACL` entry is not made for the owner of the object, since the owner will have a `SHARED_DEPENDENCY_OWNER` entry anyway.)

SHARED\_DEPENDENCY\_POLICY (r)

The referenced object (which must be a role) is mentioned as the target of a dependent policy object.

SHARED\_DEPENDENCY\_PIN (p)

There is no dependent object; this type of entry is a signal that the system itself depends on the referenced object, and so that object must never be deleted. Entries of this type are created only by `initdb`. The columns for the dependent object contain zeroes.

SHARED\_DEPENDENCY\_TABLESPACE (t)

The referenced object (which must be a tablespace) is mentioned as the tablespace for a relation that doesn't have storage.

Other dependency flavors might be needed in future. Note in particular that the current definition only supports roles and tablespaces as referenced objects.

## 49.47. `pg_shdescription`

The catalog `pg_shdescription` stores optional descriptions (comments) for shared database objects. Descriptions can be manipulated with the `COMMENT` command and viewed with `psql`'s `\d` commands.

See also `pg_description`, which performs a similar function for descriptions involving objects within a single database.

Unlike most system catalogs, `pg_shdescription` is shared across all databases of a cluster: there is only one copy of `pg_shdescription` per cluster, not one per database.

**Table 49.47. `pg_shdescription` Columns**

Column Type	Description
<code>objoid oid</code> (references any OID column)	The OID of the object this description pertains to
<code>classoid oid</code> (references <code>pg_class</code> .oid)	The OID of the system catalog this object appears in
<code>description text</code>	Arbitrary text that serves as the description of this object

## 49.48. `pg_shseclabel`

The catalog `pg_shseclabel` stores security labels on shared database objects. Security labels can be manipulated with the `SECURITY LABEL` command. For an easier way to view security labels, see [Section 49.83](#).

See also `pg_seclabel`, which performs a similar function for security labels involving objects within a single database.

Unlike most system catalogs, `pg_shseclabel` is shared across all databases of a cluster: there is only one copy of `pg_shseclabel` per cluster, not one per database.

**Table 49.48. pg\_shseclabel Columns**

Column Type	Description
objoid oid (references any OID column)	The OID of the object this security label pertains to
classoid oid (references <code>pg_class</code> .oid)	The OID of the system catalog this object appears in
provider text	The label provider associated with this label.
label text	The security label applied to this object.

## 49.49. pg\_statistic

The catalog `pg_statistic` stores statistical data about the contents of the database. Entries are created by `ANALYZE` and subsequently used by the query planner. Note that all the statistical data is inherently approximate, even assuming that it is up-to-date.

Normally there is one entry, with `stainherit = false`, for each table column that has been analyzed. If the table has inheritance children, a second entry with `stainherit = true` is also created. This row represents the column's statistics over the inheritance tree, i.e., statistics for the data you'd see with `SELECT column FROM table*`, whereas the `stainherit = false` row represents the results of `SELECT column FROM ONLY table`.

`pg_statistic` also stores statistical data about the values of index expressions. These are described as if they were actual data columns; in particular, `starelid` references the index. No entry is made for an ordinary non-expression index column, however, since it would be redundant with the entry for the underlying table column. Currently, entries for index expressions always have `stainherit = false`.

Since different kinds of statistics might be appropriate for different kinds of data, `pg_statistic` is designed not to assume very much about what sort of statistics it stores. Only extremely general statistics (such as nullness) are given dedicated columns in `pg_statistic`. Everything else is stored in “slots”, which are groups of associated columns whose content is identified by a code number in one of the slot's columns.

`pg_statistic` should not be readable by the public, since even statistical information about a table's contents might be considered sensitive. (Example: minimum and maximum values of a salary column might be quite interesting.) `pg_stats` is a publicly readable view on `pg_statistic` that only exposes information about those tables that are readable by the current user.

**Table 49.49. pg\_statistic Columns**

Column Type	Description
starelid oid (references <code>pg_class</code> .oid)	The table or index that the described column belongs to
staattnum int2 (references <code>pg_attribute</code> .attnum)	The number of the described column
stainherit bool	If true, the stats include inheritance child columns, not just the values in the specified relation
stanullfrac float4	The fraction of the column's entries that are null
stawidth int4	

Column Type	Description
	The average stored width, in bytes, of nonnull entries
<code>stadistinct float4</code>	The number of distinct nonnull data values in the column. A value greater than zero is the actual number of distinct values. A value less than zero is the negative of a multiplier for the number of rows in the table; for example, a column in which about 80% of the values are nonnull and each nonnull value appears about twice on average could be represented by <code>stadistinct = -0.4</code> . A zero value means the number of distinct values is unknown.
<code>stakindN int2</code>	A code number indicating the kind of statistics stored in the <i>n</i> th “slot” of the <code>pg_statistic</code> row.
<code>staopN oid (references pg_operator .oid)</code>	An operator used to derive the statistics stored in the <i>n</i> th “slot”. For example, a histogram slot would show the < operator that defines the sort order of the data.
<code>stacollN oid (references pg_collation .oid)</code>	The collation used to derive the statistics stored in the <i>n</i> th “slot”. For example, a histogram slot for a collatable column would show the collation that defines the sort order of the data. Zero for noncollatable data.
<code>stanumbersN float4[]</code>	Numerical statistics of the appropriate kind for the <i>n</i> th “slot”, or null if the slot kind does not involve numerical values
<code>stavaluesN anyarray</code>	Column data values of the appropriate kind for the <i>n</i> th “slot”, or null if the slot kind does not store any data values. Each array's element values are actually of the specific column's data type, or a related type such as an array's element type, so there is no way to define these columns' type more specifically than <code>anyarray</code> .

## 49.50. `pg_statistic_ext`

The catalog `pg_statistic_ext` holds definitions of extended planner statistics. Each row in this catalog corresponds to a *statistics object* created with `CREATE STATISTICS`.

**Table 49.50. `pg_statistic_ext` Columns**

Column Type	Description
<code>oid oid</code>	Row identifier
<code>stxrelid oid (references pg_class .oid)</code>	Table containing the columns described by this object
<code>stxname name</code>	Name of the statistics object
<code>stxnamespace oid (references pg_namespace .oid)</code>	The OID of the namespace that contains this statistics object
<code>stxowner oid (references pg_authid .oid)</code>	Owner of the statistics object
<code>stxstattarget int4</code>	<code>stxstattarget</code> controls the level of detail of statistics accumulated for this statistics object by <code>ANALYZE</code> . A zero value indicates that no statistics should be collected. A negative value says to use the maximum of the statistics targets of the referenced columns, if set, or the system default statistics target. Positive values of <code>stxstattarget</code> determine the target number of “most common values” to collect.

Column Type	Description
<code>stxkeys</code> <code>int2vector</code> (references <code>pg_attribute</code> <code>.attnum</code> )	An array of attribute numbers, indicating which table columns are covered by this statistics object; for example a value of <code>1 3</code> would mean that the first and the third table columns are covered
<code>stxkind</code> <code>char[]</code>	An array containing codes for the enabled statistics kinds; valid values are: <code>d</code> for n-distinct statistics, <code>f</code> for functional dependency statistics, and <code>m</code> for most common values (MCV) list statistics

The `pg_statistic_ext` entry is filled in completely during `CREATE STATISTICS`, but the actual statistical values are not computed then. Subsequent `ANALYZE` commands compute the desired values and populate an entry in the `pg_statistic_ext_data` catalog.

## 49.51. `pg_statistic_ext_data`

The catalog `pg_statistic_ext_data` holds data for extended planner statistics defined in `pg_statistic_ext`. Each row in this catalog corresponds to a *statistics object* created with `CREATE STATISTICS`.

Like `pg_statistic`, `pg_statistic_ext_data` should not be readable by the public, since the contents might be considered sensitive. (Example: most common combinations of values in columns might be quite interesting.) `pg_stats_ext` is a publicly readable view on `pg_statistic_ext_data` (after joining with `pg_statistic_ext`) that only exposes information about those tables and columns that are readable by the current user.

**Table 49.51. `pg_statistic_ext_data` Columns**

Column Type	Description
<code>stxoid</code> <code>oid</code> (references <code>pg_statistic_ext</code> <code>.oid</code> )	Extended statistic object containing the definition for this data
<code>stxdndistinct</code> <code>pg_ndistinct</code>	N-distinct counts, serialized as <code>pg_ndistinct</code> <code>type</code>
<code>stxddependencies</code> <code>pg_dependencies</code>	Functional dependency statistics, serialized as <code>pg_dependencies</code> <code>type</code>
<code>stxdmcv</code> <code>pg_mcv_list</code>	MCV (most-common values) list statistics, serialized as <code>pg_mcv_list</code> <code>type</code>

## 49.52. `pg_subscription`

The catalog `pg_subscription` contains all existing logical replication subscriptions. For more information about logical replication see [Chapter 29](#).

Unlike most system catalogs, `pg_subscription` is shared across all databases of a cluster: there is only one copy of `pg_subscription` per cluster, not one per database.

Access to the column `subconninfo` is revoked from normal users, because it could contain plain-text passwords.

**Table 49.52. `pg_subscription` Columns**

Column Type	Description
<code>oid</code> <code>oid</code>	

Column Type	Description
	Row identifier
subdbid oid (references <a href="#">pg_database</a> .oid)	OID of the database which the subscription resides in
subname name	Name of the subscription
subowner oid (references <a href="#">pg_authid</a> .oid)	Owner of the subscription
subenabled bool	If true, the subscription is enabled and should be replicating.
subconninfo text	Connection string to the upstream database
subslotname name	Name of the replication slot in the upstream database (also used for the local replication origin name); null represents NONE
subsynccommit text	Contains the value of the <code>synchronous_commit</code> setting for the subscription workers.
subpublications text[]	Array of subscribed publication names. These reference the publications on the publisher server. For more on publications see <a href="#">Section 29.1</a> .

## 49.53. `pg_subscription_rel`

The catalog `pg_subscription_rel` contains the state for each replicated relation in each subscription. This is a many-to-many mapping.

This catalog only contains tables known to the subscription after running either `CREATE SUBSCRIPTION` or `ALTER SUBSCRIPTION ... REFRESH PUBLICATION`.

**Table 49.53. `pg_subscription_rel` Columns**

Column Type	Description
srsubid oid (references <a href="#">pg_subscription</a> .oid)	Reference to subscription
srrelid oid (references <a href="#">pg_class</a> .oid)	Reference to relation
srsubstate char	State code: <code>i</code> = initialize, <code>d</code> = data is being copied, <code>s</code> = synchronized, <code>r</code> = ready (normal replication)
srsublsn pg_lsn	Remote LSN of the state change used for synchronization coordination when in <code>s</code> or <code>r</code> states, otherwise null

## 49.54. `pg_tablespace`

The catalog `pg_tablespace` stores information about the available tablespaces. Tables can be placed in particular tablespaces to aid administration of disk layout.

Unlike most system catalogs, `pg_tablespace` is shared across all databases of a cluster: there is only one copy of `pg_tablespace` per cluster, not one per database.

**Table 49.54. pg\_tablespace Columns**

Column Type	Description
oid oid	Row identifier
spcname name	Tablespace name
spcowner oid (references <a href="#">pg_authid</a> .oid)	Owner of the tablespace, usually the user who created it
spcacl aclitem[]	Access privileges; see <a href="#">Section 5.7</a> for details
spcoptions text[]	Tablespace-level options, as “keyword=value” strings

## 49.55. pg\_transform

The catalog `pg_transform` stores information about transforms, which are a mechanism to adapt data types to procedural languages. See [CREATE TRANSFORM](#) for more information.

**Table 49.55. pg\_transform Columns**

Column Type	Description
oid oid	Row identifier
trftype oid (references <a href="#">pg_type</a> .oid)	OID of the data type this transform is for
trflang oid (references <a href="#">pg_language</a> .oid)	OID of the language this transform is for
trffromsql regproc (references <a href="#">pg_proc</a> .oid)	The OID of the function to use when converting the data type for input to the procedural language (e.g., function parameters). Zero is stored if this operation is not supported.
trftosql regproc (references <a href="#">pg_proc</a> .oid)	The OID of the function to use when converting output from the procedural language (e.g., return values) to the data type. Zero is stored if this operation is not supported.

## 49.56. pg\_trigger

The catalog `pg_trigger` stores triggers on tables and views. See [CREATE TRIGGER](#) for more information.

**Table 49.56. pg\_trigger Columns**

Column Type	Description
oid oid	Row identifier
tgrelid oid (references <a href="#">pg_class</a> .oid)	The table this trigger is on
tgparentid oid (references <a href="#">pg_trigger</a> .oid)	Parent trigger that this trigger is cloned from, zero if not a clone; this happens when partitions are created or attached to a partitioned table.

<b>Column Type</b>	<b>Description</b>
tgname name	Trigger name (must be unique among triggers of same table)
tgfoid oid (references <code>pg_proc</code> .oid)	The function to be called
tgtype int2	Bit mask identifying trigger firing conditions
tgenabled char	Controls in which <code>session_replication_role</code> modes the trigger fires. <code>O</code> = trigger fires in “origin” and “local” modes, <code>D</code> = trigger is disabled, <code>R</code> = trigger fires in “replica” mode, <code>A</code> = trigger fires always.
tgisinternal bool	True if trigger is internally generated (usually, to enforce the constraint identified by <code>tgconstraint</code> )
tgconstrrelid oid (references <code>pg_class</code> .oid)	The table referenced by a referential integrity constraint
tgconstrindid oid (references <code>pg_class</code> .oid)	The index supporting a unique, primary key, referential integrity, or exclusion constraint
tgconstraint oid (references <code>pg_constraint</code> .oid)	The <code>pg_constraint</code> entry associated with the trigger, if any
tgdeferrable bool	True if constraint trigger is deferrable
tginitdeferred bool	True if constraint trigger is initially deferred
tgargs int2	Number of argument strings passed to trigger function
tgattr int2vector (references <code>pg_attribute</code> .attnum)	Column numbers, if trigger is column-specific; otherwise an empty array
tgargs bytea	Argument strings to pass to trigger, each NULL-terminated
tgqual pg_node_tree	Expression tree (in <code>nodeToString()</code> representation) for the trigger's <code>WHEN</code> condition, or null if none
tgoldtable name	<code>REFERENCING</code> clause name for <code>OLD TABLE</code> , or null if none
tgnewtable name	<code>REFERENCING</code> clause name for <code>NEW TABLE</code> , or null if none

Currently, column-specific triggering is supported only for `UPDATE` events, and so `tgattr` is relevant only for that event type. `tgtype` might contain bits for other event types as well, but those are presumed to be table-wide regardless of what is in `tgattr`.

### Note

When `tgconstraint` is nonzero, `tgconstrrelid`, `tgconstrindid`, `tgdeferrable`, and `tginitdeferred` are largely redundant with the referenced `pg_constraint` entry. However, it is possible for a non-deferrable trigger to be associated with a deferrable constraint: foreign key constraints can have some deferrable and some non-deferrable triggers.

**Note**

`pg_class.relhastriggers` must be true if a relation has any triggers in this catalog.

**49.57. `pg_ts_config`**

The `pg_ts_config` catalog contains entries representing text search configurations. A configuration specifies a particular text search parser and a list of dictionaries to use for each of the parser's output token types. The parser is shown in the `pg_ts_config` entry, but the token-to-dictionary mapping is defined by subsidiary entries in `pg_ts_config_map`.

Postgres Pro's text search features are described at length in [Chapter 12](#).

**Table 49.57. `pg_ts_config` Columns**

Column Type	Description
oid oid	Row identifier
cfgname name	Text search configuration name
cfgnamespace oid (references <a href="#">pg_namespace</a> .oid)	The OID of the namespace that contains this configuration
cfgowner oid (references <a href="#">pg_authid</a> .oid)	Owner of the configuration
cfgparser oid (references <a href="#">pg_ts_parser</a> .oid)	The OID of the text search parser for this configuration

**49.58. `pg_ts_config_map`**

The `pg_ts_config_map` catalog contains entries showing which text search dictionaries should be consulted, and in what order, for each output token type of each text search configuration's parser.

Postgres Pro's text search features are described at length in [Chapter 12](#).

**Table 49.58. `pg_ts_config_map` Columns**

Column Type	Description
mapcfg oid (references <a href="#">pg_ts_config</a> .oid)	The OID of the <code>pg_ts_config</code> entry owning this map entry
maptokentype int4	A token type emitted by the configuration's parser
mapseqno int4	Order in which to consult this entry (lower <code>mapseqnos</code> first)
mapdict oid (references <a href="#">pg_ts_dict</a> .oid)	The OID of the text search dictionary to consult

**49.59. `pg_ts_dict`**

The `pg_ts_dict` catalog contains entries defining text search dictionaries. A dictionary depends on a text search template, which specifies all the implementation functions needed; the dictionary itself provides values for the user-settable parameters supported by the template. This division of labor allows dictionaries to be created by unprivileged users. The parameters are specified by a text string `dictinitoption`, whose format and meaning vary depending on the template.

Postgres Pro's text search features are described at length in [Chapter 12](#).

**Table 49.59. `pg_ts_dict` Columns**

Column Type	Description
oid oid	Row identifier
dictname name	Text search dictionary name
dictnamespace oid (references <a href="#">pg_namespace</a> .oid)	The OID of the namespace that contains this dictionary
dictowner oid (references <a href="#">pg_authid</a> .oid)	Owner of the dictionary
dicttemplate oid (references <a href="#">pg_ts_template</a> .oid)	The OID of the text search template for this dictionary
dictinitoption text	Initialization option string for the template

## 49.60. `pg_ts_parser`

The `pg_ts_parser` catalog contains entries defining text search parsers. A parser is responsible for splitting input text into lexemes and assigning a token type to each lexeme. Since a parser must be implemented by C-language-level functions, creation of new parsers is restricted to database superusers.

Postgres Pro's text search features are described at length in [Chapter 12](#).

**Table 49.60. `pg_ts_parser` Columns**

Column Type	Description
oid oid	Row identifier
prsname name	Text search parser name
prsnamespace oid (references <a href="#">pg_namespace</a> .oid)	The OID of the namespace that contains this parser
prsstart regproc (references <a href="#">pg_proc</a> .oid)	OID of the parser's startup function
prstoken regproc (references <a href="#">pg_proc</a> .oid)	OID of the parser's next-token function
prsend regproc (references <a href="#">pg_proc</a> .oid)	OID of the parser's shutdown function
prsheadline regproc (references <a href="#">pg_proc</a> .oid)	OID of the parser's headline function
prsllextype regproc (references <a href="#">pg_proc</a> .oid)	OID of the parser's lextype function

## 49.61. `pg_ts_template`

The `pg_ts_template` catalog contains entries defining text search templates. A template is the implementation skeleton for a class of text search dictionaries. Since a template must be implemented by C-language-level functions, creation of new templates is restricted to database superusers.

Postgres Pro's text search features are described at length in [Chapter 12](#).

**Table 49.61. `pg_ts_template` Columns**

Column Type	Description
oid oid	Row identifier
tmplname name	Text search template name
tmplnamespace oid (references <a href="#">pg_namespace</a> .oid)	The OID of the namespace that contains this template
tmplinit regproc (references <a href="#">pg_proc</a> .oid)	OID of the template's initialization function
tmpllexize regproc (references <a href="#">pg_proc</a> .oid)	OID of the template's lexize function

## 49.62. `pg_type`

The catalog `pg_type` stores information about data types. Base types and enum types (scalar types) are created with [CREATE TYPE](#), and domains with [CREATE DOMAIN](#). A composite type is automatically created for each table in the database, to represent the row structure of the table. It is also possible to create composite types with `CREATE TYPE AS`.

**Table 49.62. `pg_type` Columns**

Column Type	Description
oid oid	Row identifier
typname name	Data type name
typnamespace oid (references <a href="#">pg_namespace</a> .oid)	The OID of the namespace that contains this type
typowner oid (references <a href="#">pg_authid</a> .oid)	Owner of the type
typlen int2	For a fixed-size type, <code>typlen</code> is the number of bytes in the internal representation of the type. But for a variable-length type, <code>typlen</code> is negative. -1 indicates a “varlena” type (one that has a length word), -2 indicates a null-terminated C string.
typbyval bool	<code>typbyval</code> determines whether internal routines pass a value of this type by value or by reference. <code>typbyval</code> had better be false if <code>typlen</code> is not 1, 2, or 4 (or 8 on machines where Datum is 8 bytes). Variable-length types are always passed by reference. Note that <code>typbyval</code> can be false even if the length would allow pass-by-value.
typtype char	<code>typtype</code> is <code>b</code> for a base type, <code>c</code> for a composite type (e.g., a table's row type), <code>d</code> for a domain, <code>e</code> for an enum type, <code>p</code> for a pseudo-type, or <code>r</code> for a range type. See also <code>typrelid</code> and <code>typbasetype</code> .
typcategory char	<code>typcategory</code> is an arbitrary classification of data types that is used by the parser to determine which implicit casts should be “preferred”. See <a href="#">Table 49.63</a> .
typispreferred bool	

<b>Column Type</b>	<b>Description</b>
	True if the type is a preferred cast target within its <code>typcategory</code>
<code>typisdefined</code> bool	True if the type is defined, false if this is a placeholder entry for a not-yet-defined type. When <code>typisdefined</code> is false, nothing except the type name, namespace, and OID can be relied on.
<code>typdelim</code> char	Character that separates two values of this type when parsing array input. Note that the delimiter is associated with the array element data type, not the array data type.
<code>typrelid</code> oid (references <code>pg_class</code> .oid)	If this is a composite type (see <code>typtype</code> ), then this column points to the <code>pg_class</code> entry that defines the corresponding table. (For a free-standing composite type, the <code>pg_class</code> entry doesn't really represent a table, but it is needed anyway for the type's <code>pg_attribute</code> entries to link to.) Zero for non-composite types.
<code>typelem</code> oid (references <code>pg_type</code> .oid)	If <code>typelem</code> is not 0 then it identifies another row in <code>pg_type</code> . The current type can then be subscripted like an array yielding values of type <code>typelem</code> . A “true” array type is variable length ( <code>typelen = -1</code> ), but some fixed-length ( <code>typelen &gt; 0</code> ) types also have nonzero <code>typelem</code> , for example <code>name</code> and <code>point</code> . If a fixed-length type has a <code>typelem</code> then its internal representation must be some number of values of the <code>typelem</code> data type with no other data. Variable-length array types have a header defined by the array subroutines.
<code>typarray</code> oid (references <code>pg_type</code> .oid)	If <code>typarray</code> is not 0 then it identifies another row in <code>pg_type</code> , which is the “true” array type having this type as element
<code>typinput</code> regproc (references <code>pg_proc</code> .oid)	Input conversion function (text format)
<code>typoutput</code> regproc (references <code>pg_proc</code> .oid)	Output conversion function (text format)
<code>typreceive</code> regproc (references <code>pg_proc</code> .oid)	Input conversion function (binary format), or 0 if none
<code>typsend</code> regproc (references <code>pg_proc</code> .oid)	Output conversion function (binary format), or 0 if none
<code>typmodin</code> regproc (references <code>pg_proc</code> .oid)	Type modifier input function, or 0 if type does not support modifiers
<code>typmodout</code> regproc (references <code>pg_proc</code> .oid)	Type modifier output function, or 0 to use the standard format
<code>typanalyze</code> regproc (references <code>pg_proc</code> .oid)	Custom ANALYZE function, or 0 to use the standard function
<code>typalign</code> char	<p><code>typalign</code> is the alignment required when storing a value of this type. It applies to storage on disk as well as most representations of the value inside Postgres Pro. When multiple values are stored consecutively, such as in the representation of a complete row on disk, padding is inserted before a datum of this type so that it begins on the specified boundary. The alignment reference is the beginning of the first datum in the sequence. Possible values are:</p> <ul style="list-style-type: none"> <li>• <code>c</code> = char alignment, i.e., no alignment needed.</li> <li>• <code>s</code> = short alignment (2 bytes on most machines).</li> <li>• <code>i</code> = int alignment (4 bytes on most machines).</li> <li>• <code>d</code> = double alignment (8 bytes on many machines, but by no means all).</li> </ul>

Column Type	Description
<code>typstorage</code> char	<p><code>typstorage</code> tells for varlena types (those with <code>typplen = -1</code>) if the type is prepared for toasting and what the default strategy for attributes of this type should be. Possible values are:</p> <ul style="list-style-type: none"> <li>• <code>p</code> (plain): Values must always be stored plain (non-varlena types always use this value).</li> <li>• <code>e</code> (external): Values can be stored in a secondary “TOAST” relation (if relation has one, see <code>pg_class.reltoastrelid</code>).</li> <li>• <code>m</code> (main): Values can be compressed and stored inline.</li> <li>• <code>x</code> (extended): Values can be compressed and/or moved to a secondary relation.</li> </ul> <p><code>x</code> is the usual choice for toast-able types. Note that <code>m</code> values can also be moved out to secondary storage, but only as a last resort (<code>e</code> and <code>x</code> values are moved first).</p>
<code>typnotnull</code> bool	<code>typnotnull</code> represents a not-null constraint on a type. Used for domains only.
<code>typbasetype</code> oid (references <code>pg_type</code> .oid)	If this is a domain (see <code>typtype</code> ), then <code>typbasetype</code> identifies the type that this one is based on. Zero if this type is not a domain.
<code>tyttypmod</code> int4	Domains use <code>tyttypmod</code> to record the <code>typmod</code> to be applied to their base type (-1 if base type does not use a <code>typmod</code> ). -1 if this type is not a domain.
<code>typndims</code> int4	<code>typndims</code> is the number of array dimensions for a domain over an array (that is, <code>typbasetype</code> is an array type). Zero for types other than domains over array types.
<code>typcollation</code> oid (references <code>pg_collation</code> .oid)	<code>typcollation</code> specifies the collation of the type. If the type does not support collations, this will be zero. A base type that supports collations will have a nonzero value here, typically <code>DEFAULT_COLLATION_OID</code> . A domain over a collatable type can have a collation OID different from its base type's, if one was specified for the domain.
<code>typdefaultbin</code> pg_node_tree	If <code>typdefaultbin</code> is not null, it is the <code>nodeToString()</code> representation of a default expression for the type. This is only used for domains.
<code>typdefault</code> text	<code>typdefault</code> is null if the type has no associated default value. If <code>typdefaultbin</code> is not null, <code>typdefault</code> must contain a human-readable version of the default expression represented by <code>typdefaultbin</code> . If <code>typdefaultbin</code> is null and <code>typdefault</code> is not, then <code>typdefault</code> is the external representation of the type's default value, which can be fed to the type's input converter to produce a constant.
<code>typacl</code> aclitem[]	Access privileges; see <a href="#">Section 5.7</a> for details

### Note

For fixed-width types used in system tables, it is critical that the size and alignment defined in `pg_type` agree with the way that the compiler will lay out the column in a structure representing a table row.

[Table 49.63](#) lists the system-defined values of `typcategory`. Any future additions to this list will also be upper-case ASCII letters. All other ASCII characters are reserved for user-defined categories.

**Table 49.63. `typcategory` Codes**

Code	Category
A	Array types
B	Boolean types
C	Composite types
D	Date/time types
E	Enum types
G	Geometric types
I	Network address types
N	Numeric types
P	Pseudo-types
R	Range types
S	String types
T	Timespan types
U	User-defined types
V	Bit-string types
X	unknown type

## 49.63. `pg_user_mapping`

The catalog `pg_user_mapping` stores the mappings from local user to remote. Access to this catalog is restricted from normal users, use the view `pg_user_mappings` instead.

**Table 49.64. `pg_user_mapping` Columns**

Column Type	Description
<code>oid oid</code>	Row identifier
<code>umuser oid (references <code>pg_authid</code> .oid)</code>	OID of the local role being mapped, 0 if the user mapping is public
<code>umserver oid (references <code>pg_foreign_server</code> .oid)</code>	The OID of the foreign server that contains this mapping
<code>umoptions text []</code>	User mapping specific options, as “keyword=value” strings

## 49.64. System Views

In addition to the system catalogs, Postgres Pro provides a number of built-in views. Some system views provide convenient access to some commonly used queries on the system catalogs. Other views provide access to internal server state.

The information schema ([Chapter 34](#)) provides an alternative set of views which overlap the functionality of the system views. Since the information schema is SQL-standard whereas the views described here are Postgres Pro-specific, it's usually better to use the information schema if it provides all the information you need.

[Table 49.65](#) lists the system views described here. More detailed documentation of each view follows below. There are some additional views that provide access to the results of the statistics collector; they are described in [Table 26.2](#).

Except where noted, all the views described here are read-only.

**Table 49.65. System Views**

View Name	Purpose
<code>pg_available_extensions</code>	available extensions
<code>pg_available_extension_versions</code>	available versions of extensions
<code>pg_config</code>	compile-time configuration parameters
<code>pg_cursors</code>	open cursors
<code>pg_file_settings</code>	summary of configuration file contents
<code>pg_group</code>	groups of database users
<code>pg_hba_file_rules</code>	summary of client authentication configuration file contents
<code>pg_indexes</code>	indexes
<code>pg_locks</code>	locks currently held or awaited
<code>pg_matviews</code>	materialized views
<code>pg_policies</code>	policies
<code>pg_prepared_statements</code>	prepared statements
<code>pg_prepared_xacts</code>	prepared transactions
<code>pg_publication_tables</code>	publications and their associated tables
<code>pg_replication_origin_status</code>	information about replication origins, including replication progress
<code>pg_replication_slots</code>	replication slot information

<code>pg_user_mappings</code>	user mappings
<code>pg_views</code>	views

## 49.65. `pg_available_extensions`

The `pg_available_extensions` view lists the extensions that are available for installation. See also the `pg_extension` catalog, which shows the extensions currently installed.

**Table 49.66. pg\_available\_extensions Columns**

Column Type	Description
name name	Extension name
default_version text	Name of default version, or NULL if none is specified
installed_version text	Currently installed version of the extension, or NULL if not installed
comment text	Comment string from the extension's control file

The `pg_available_extensions` view is read only.

## 49.66. pg\_available\_extension\_versions

The `pg_available_extension_versions` view lists the specific extension versions that are available for installation. See also the `pg_extension` catalog, which shows the extensions currently installed.

**Table 49.67. pg\_available\_extension\_versions Columns**

Column Type	Description
name name	Extension name
version text	Version name
installed bool	True if this version of this extension is currently installed
superuser bool	True if only superusers are allowed to install this extension (but see <code>trusted</code> )
trusted bool	True if the extension can be installed by non-superusers with appropriate privileges
relocatable bool	True if extension can be relocated to another schema
schema name	Name of the schema that the extension must be installed into, or NULL if partially or fully relocatable
requires name[]	Names of prerequisite extensions, or NULL if none
comment text	Comment string from the extension's control file

The `pg_available_extension_versions` view is read only.

## 49.67. pg\_config

The view `pg_config` describes the compile-time configuration parameters of the currently installed version of Postgres Pro. It is intended, for example, to be used by software packages that want to interface to Postgres Pro to facilitate finding the required header files and libraries. It provides the same basic information as the `pg_config` Postgres Pro client application.

By default, the `pg_config` view can be read only by superusers.

**Table 49.68. pg\_config Columns**

Column Type	Description
name text	The parameter name
setting text	The parameter value

## 49.68. pg\_cursors

The `pg_cursors` view lists the cursors that are currently available. Cursors can be defined in several ways:

- via the [DECLARE](#) statement in SQL
- via the Bind message in the frontend/backend protocol, as described in [Section 50.2.3](#)
- via the Server Programming Interface (SPI), as described in [Section 44.1](#)

The `pg_cursors` view displays cursors created by any of these means. Cursors only exist for the duration of the transaction that defines them, unless they have been declared `WITH HOLD`. Therefore non-holdable cursors are only present in the view until the end of their creating transaction.

### Note

Cursors are used internally to implement some of the components of Postgres Pro, such as procedural languages. Therefore, the `pg_cursors` view might include cursors that have not been explicitly created by the user.

**Table 49.69. pg\_cursors Columns**

Column Type	Description
name text	The name of the cursor
statement text	The verbatim query string submitted to declare this cursor
is_holdable bool	true if the cursor is holdable (that is, it can be accessed after the transaction that declared the cursor has committed); false otherwise
is_binary bool	true if the cursor was declared <code>BINARY</code> ; false otherwise
is_scrollable bool	true if the cursor is scrollable (that is, it allows rows to be retrieved in a nonsequential manner); false otherwise
creation_time timestamptz	The time at which the cursor was declared

The `pg_cursors` view is read only.

## 49.69. pg\_file\_settings

The view `pg_file_settings` provides a summary of the contents of the server's configuration file(s). A row appears in this view for each “name = value” entry appearing in the files, with annotations indicating whether the value could be applied successfully. Additional row(s) may appear for problems not linked to a “name = value” entry, such as syntax errors in the files.

This view is helpful for checking whether planned changes in the configuration files will work, or for diagnosing a previous failure. Note that this view reports on the *current* contents of the files, not on what was last applied by the server. (The `pg_settings` view is usually sufficient to determine that.)

By default, the `pg_file_settings` view can be read only by superusers.

**Table 49.70. `pg_file_settings` Columns**

Column Type	Description
sourcefile text	Full path name of the configuration file
sourceline int4	Line number within the configuration file where the entry appears
seqno int4	Order in which the entries are processed (1..n)
name text	Configuration parameter name
setting text	Value to be assigned to the parameter
applied bool	True if the value can be applied successfully
error text	If not null, an error message indicating why this entry could not be applied

If the configuration file contains syntax errors or invalid parameter names, the server will not attempt to apply any settings from it, and therefore all the `applied` fields will read as false. In such a case there will be one or more rows with non-null `error` fields indicating the problem(s). Otherwise, individual settings will be applied if possible. If an individual setting cannot be applied (e.g., invalid value, or the setting cannot be changed after server start) it will have an appropriate message in the `error` field. Another way that an entry might have `applied = false` is that it is overridden by a later entry for the same parameter name; this case is not considered an error so nothing appears in the `error` field.

See [Section 18.1](#) for more information about the various ways to change run-time parameters.

## 49.70. `pg_group`

The view `pg_group` exists for backwards compatibility: it emulates a catalog that existed in PostgreSQL before version 8.1. It shows the names and members of all roles that are marked as `not rolcanlogin`, which is an approximation to the set of roles that are being used as groups.

**Table 49.71. `pg_group` Columns**

Column Type	Description
groname name (references <code>pg_authid</code> .rolname)	Name of the group
grosysid oid (references <code>pg_authid</code> .oid)	ID of this group
grolist oid[] (references <code>pg_authid</code> .oid)	An array containing the IDs of the roles in this group

## 49.71. `pg_hba_file_rules`

The view `pg_hba_file_rules` provides a summary of the contents of the client authentication configuration file, `pg_hba.conf`. A row appears in this view for each non-empty, non-comment line in the file, with annotations indicating whether the rule could be applied successfully.

This view can be helpful for checking whether planned changes in the authentication configuration file will work, or for diagnosing a previous failure. Note that this view reports on the *current* contents of the file, not on what was last loaded by the server.

By default, the `pg_hba_file_rules` view can be read only by superusers.

**Table 49.72. `pg_hba_file_rules` Columns**

Column Type	Description
<code>line_number int4</code>	Line number of this rule in <code>pg_hba.conf</code>
<code>type text</code>	Type of connection
<code>database text []</code>	List of database name(s) to which this rule applies
<code>user_name text []</code>	List of user and group name(s) to which this rule applies
<code>address text</code>	Host name or IP address, or one of <code>all</code> , <code>samehost</code> , or <code>samenet</code> , or null for local connections
<code>netmask text</code>	IP address mask, or null if not applicable
<code>auth_method text</code>	Authentication method
<code>options text []</code>	Options specified for authentication method, if any
<code>error text</code>	If not null, an error message indicating why this line could not be processed

Usually, a row reflecting an incorrect entry will have values for only the `line_number` and `error` fields.

See [Chapter 19](#) for more information about client authentication configuration.

## 49.72. `pg_indexes`

The view `pg_indexes` provides access to useful information about each index in the database.

**Table 49.73. `pg_indexes` Columns**

Column Type	Description
<code>schemaname name (references <a href="#">pg_namespace</a> .nspname)</code>	Name of schema containing table and index
<code>tablename name (references <a href="#">pg_class</a> .relname)</code>	Name of table the index is for
<code>indexname name (references <a href="#">pg_class</a> .relname)</code>	Name of index
<code>tablespace name (references <a href="#">pg_tablespace</a> .spcname)</code>	Name of tablespace containing index (null if default for database)
<code>indexdef text</code>	Index definition (a reconstructed <code>CREATE INDEX</code> command)

## 49.73. pg\_locks

The view `pg_locks` provides access to information about the locks held by active processes within the database server. See [Chapter 13](#) for more discussion of locking.

`pg_locks` contains one row per active lockable object, requested lock mode, and relevant process. Thus, the same lockable object might appear many times, if multiple processes are holding or waiting for locks on it. However, an object that currently has no locks on it will not appear at all.

There are several distinct types of lockable objects: whole relations (e.g., tables), individual pages of relations, individual tuples of relations, transaction IDs (both virtual and permanent IDs), and general database objects (identified by class OID and object OID, in the same way as in `pg_description` or `pg_depend`). Also, the right to extend a relation is represented as a separate lockable object, as is the right to update `pg_database.datfrozenxid`. Also, “advisory” locks can be taken on numbers that have user-defined meanings.

**Table 49.74. pg\_locks Columns**

Column	Type	Description
<code>locktype</code>	text	Type of the lockable object: <code>relation</code> , <code>extend</code> , <code>frozenid</code> , <code>page</code> , <code>tuple</code> , <code>transactionid</code> , <code>virtualxid</code> , <code>spectoken</code> , <code>object</code> , <code>userlock</code> , or <code>advisory</code> . (See also <a href="#">Table 26.11</a> .)
<code>database</code>	oid (references <code>pg_database.oid</code> )	OID of the database in which the lock target exists, or zero if the target is a shared object, or null if the target is a transaction ID
<code>relation</code>	oid (references <code>pg_class.oid</code> )	OID of the relation targeted by the lock, or null if the target is not a relation or part of a relation
<code>page</code>	int4	Page number targeted by the lock within the relation, or null if the target is not a relation page or tuple
<code>tuple</code>	int2	Tuple number targeted by the lock within the page, or null if the target is not a tuple
<code>virtualxid</code>	text	Virtual ID of the transaction targeted by the lock, or null if the target is not a virtual transaction ID
<code>transactionid</code>	xid	ID of the transaction targeted by the lock, or null if the target is not a transaction ID
<code>classid</code>	oid (references <code>pg_class.oid</code> )	OID of the system catalog containing the lock target, or null if the target is not a general database object
<code>objid</code>	oid (references any OID column)	OID of the lock target within its system catalog, or null if the target is not a general database object
<code>objsubid</code>	int2	Column number targeted by the lock (the <code>classid</code> and <code>objid</code> refer to the table itself), or zero if the target is some other general database object, or null if the target is not a general database object
<code>virtualtransaction</code>	text	Virtual ID of the transaction that is holding or awaiting this lock
<code>pid</code>	int4	Process ID of the server process holding or awaiting this lock, or null if the lock is held by a prepared transaction

Column Type	Description
mode text	Name of the lock mode held or desired by this process (see <a href="#">Section 13.3.1</a> and <a href="#">Section 13.2.3</a> )
granted bool	True if lock is held, false if lock is awaited
fastpath bool	True if lock was taken via fast path, false if taken via main lock table

`granted` is true in a row representing a lock held by the indicated process. False indicates that this process is currently waiting to acquire this lock, which implies that at least one other process is holding or waiting for a conflicting lock mode on the same lockable object. The waiting process will sleep until the other lock is released (or a deadlock situation is detected). A single process can be waiting to acquire at most one lock at a time.

Throughout running a transaction, a server process holds an exclusive lock on the transaction's virtual transaction ID. If a permanent ID is assigned to the transaction (which normally happens only if the transaction changes the state of the database), it also holds an exclusive lock on the transaction's permanent transaction ID until it ends. When a process finds it necessary to wait specifically for another transaction to end, it does so by attempting to acquire share lock on the other transaction's ID (either virtual or permanent ID depending on the situation). That will succeed only when the other transaction terminates and releases its locks.

Although tuples are a lockable type of object, information about row-level locks is stored on disk, not in memory, and therefore row-level locks normally do not appear in this view. If a process is waiting for a row-level lock, it will usually appear in the view as waiting for the permanent transaction ID of the current holder of that row lock.

Advisory locks can be acquired on keys consisting of either a single `bigint` value or two integer values. A `bigint` key is displayed with its high-order half in the `classid` column, its low-order half in the `objid` column, and `objsubid` equal to 1. The original `bigint` value can be reassembled with the expression `(classid::bigint << 32) | objid::bigint`. Integer keys are displayed with the first key in the `classid` column, the second key in the `objid` column, and `objsubid` equal to 2. The actual meaning of the keys is up to the user. Advisory locks are local to each database, so the `database` column is meaningful for an advisory lock.

`pg_locks` provides a global view of all locks in the database cluster, not only those relevant to the current database. Although its `relation` column can be joined against `pg_class.oid` to identify locked relations, this will only work correctly for relations in the current database (those for which the `database` column is either the current database's OID or zero).

The `pid` column can be joined to the `pid` column of the `pg_stat_activity` view to get more information on the session holding or awaiting each lock, for example

```
SELECT * FROM pg_locks pl LEFT JOIN pg_stat_activity psa
ON pl.pid = psa.pid;
```

Also, if you are using prepared transactions, the `virtualtransaction` column can be joined to the `transaction` column of the `pg_prepared_xacts` view to get more information on prepared transactions that hold locks. (A prepared transaction can never be waiting for a lock, but it continues to hold the locks it acquired while running.) For example:

```
SELECT * FROM pg_locks pl LEFT JOIN pg_prepared_xacts ppx
ON pl.virtualtransaction = '-1/' || ppx.transaction;
```

While it is possible to obtain information about which processes block which other processes by joining `pg_locks` against itself, this is very difficult to get right in detail. Such a query would have to encode knowledge about which lock modes conflict with which others. Worse, the `pg_locks` view does not expose information about which processes are ahead of which others in lock wait queues, nor information about which processes are parallel workers running on behalf of which other client sessions. It is better to

use the `pg_blocking_pids()` function (see [Table 9.63](#)) to identify which process(es) a waiting process is blocked behind.

The `pg_locks` view displays data from both the regular lock manager and the predicate lock manager, which are separate systems; in addition, the regular lock manager subdivides its locks into regular and *fast-path* locks. This data is not guaranteed to be entirely consistent. When the view is queried, data on fast-path locks (with `fastpath = true`) is gathered from each backend one at a time, without freezing the state of the entire lock manager, so it is possible for locks to be taken or released while information is gathered. Note, however, that these locks are known not to conflict with any other lock currently in place. After all backends have been queried for fast-path locks, the remainder of the regular lock manager is locked as a unit, and a consistent snapshot of all remaining locks is collected as an atomic action. After unlocking the regular lock manager, the predicate lock manager is similarly locked and all predicate locks are collected as an atomic action. Thus, with the exception of fast-path locks, each lock manager will deliver a consistent set of results, but as we do not lock both lock managers simultaneously, it is possible for locks to be taken or released after we interrogate the regular lock manager and before we interrogate the predicate lock manager.

Locking the regular and/or predicate lock manager could have some impact on database performance if this view is very frequently accessed. The locks are held only for the minimum amount of time necessary to obtain data from the lock managers, but this does not completely eliminate the possibility of a performance impact.

## 49.74. `pg_matviews`

The view `pg_matviews` provides access to useful information about each materialized view in the database.

**Table 49.75. `pg_matviews` Columns**

Column Type	Description
schemaname name (references <a href="#">pg_namespace</a> .nspname)	Name of schema containing materialized view
matviewname name (references <a href="#">pg_class</a> .relname)	Name of materialized view
matviewowner name (references <a href="#">pg_authid</a> .rolname)	Name of materialized view's owner
tablespace name (references <a href="#">pg_tablespace</a> .spcname)	Name of tablespace containing materialized view (null if default for database)
hasindexes bool	True if materialized view has (or recently had) any indexes
ispopulated bool	True if materialized view is currently populated
definition text	Materialized view definition (a reconstructed <code>SELECT</code> query)

## 49.75. `pg_policies`

The view `pg_policies` provides access to useful information about each row-level security policy in the database.

**Table 49.76. `pg_policies` Columns**

Column Type	Description
schemaname name (references <a href="#">pg_namespace</a> .nspname)	

Column Type	Description
	Name of schema containing table policy is on
tablename name (references <code>pg_class</code> .relname)	Name of table policy is on
policyname name (references <code>pg_policy</code> .polname)	Name of policy
permissive text	Is the policy permissive or restrictive?
roles name[]	The roles to which this policy applies
cmd text	The command type to which the policy is applied
qual text	The expression added to the security barrier qualifications for queries that this policy applies to
with_check text	The expression added to the WITH CHECK qualifications for queries that attempt to add rows to this table

## 49.76. pg\_prepared\_statements

The `pg_prepared_statements` view displays all the prepared statements that are available in the current session. See [PREPARE](#) for more information about prepared statements.

`pg_prepared_statements` contains one row for each prepared statement. Rows are added to the view when a new prepared statement is created and removed when a prepared statement is released (for example, via the [DEALLOCATE](#) command).

**Table 49.77. pg\_prepared\_statements Columns**

Column Type	Description
name text	The identifier of the prepared statement
statement text	The query string submitted by the client to create this prepared statement. For prepared statements created via SQL, this is the <code>PREPARE</code> statement submitted by the client. For prepared statements created via the frontend/backend protocol, this is the text of the prepared statement itself.
prepare_time timestamptz	The time at which the prepared statement was created
parameter_types regtype[]	The expected parameter types for the prepared statement in the form of an array of <code>regtype</code> . The OID corresponding to an element of this array can be obtained by casting the <code>regtype</code> value to <code>oid</code> .
from_sql bool	<code>true</code> if the prepared statement was created via the <code>PREPARE</code> SQL command; <code>false</code> if the statement was prepared via the frontend/backend protocol

The `pg_prepared_statements` view is read only.

## 49.77. pg\_prepared\_xacts

The view `pg_prepared_xacts` displays information about transactions that are currently prepared for two-phase commit (see [PREPARE TRANSACTION](#) for details).

`pg_prepared_xacts` contains one row per prepared transaction. An entry is removed when the transaction is committed or rolled back.

**Table 49.78. `pg_prepared_xacts` Columns**

Column Type	Description
<code>transaction_xid</code>	Numeric transaction identifier of the prepared transaction
<code>gid_text</code>	Global transaction identifier that was assigned to the transaction
<code>prepared_timestampz</code>	Time at which the transaction was prepared for commit
<code>owner_name</code> (references <code>pg_authid</code> .rolname)	Name of the user that executed the transaction
<code>database_name</code> (references <code>pg_database</code> .datname)	Name of the database in which the transaction was executed

When the `pg_prepared_xacts` view is accessed, the internal transaction manager data structures are momentarily locked, and a copy is made for the view to display. This ensures that the view produces a consistent set of results, while not blocking normal operations longer than necessary. Nonetheless there could be some impact on database performance if this view is frequently accessed.

## 49.78. `pg_publication_tables`

The view `pg_publication_tables` provides information about the mapping between publications and the tables they contain. Unlike the underlying catalog `pg_publication_rel`, this view expands publications defined as `FOR ALL TABLES`, so for such publications there will be a row for each eligible table.

**Table 49.79. `pg_publication_tables` Columns**

Column Type	Description
<code>pubname_name</code> (references <code>pg_publication</code> .pubname)	Name of publication
<code>schemaname_name</code> (references <code>pg_namespace</code> .nspname)	Name of schema containing table
<code>tablename_name</code> (references <code>pg_class</code> .relname)	Name of table

## 49.79. `pg_replication_origin_status`

The `pg_replication_origin_status` view contains information about how far replay for a certain origin has progressed. For more on replication origins see [Chapter 47](#).

**Table 49.80. `pg_replication_origin_status` Columns**

Column Type	Description
<code>local_id</code> oid (references <code>pg_replication_origin</code> .roident)	internal node identifier
<code>external_id</code> text (references <code>pg_replication_origin</code> .roname)	

Column Type	Description
	external node identifier
remote_lsn pg_lsn	The origin node's LSN up to which data has been replicated.
local_lsn pg_lsn	This node's LSN at which <code>remote_lsn</code> has been replicated. Used to flush commit records before persisting data to disk when using asynchronous commits.

## 49.80. pg\_replication\_slots

The `pg_replication_slots` view provides a listing of all replication slots that currently exist on the database cluster, along with their current state.

For more on replication slots, see [Section 25.2.6](#) and [Chapter 46](#).

**Table 49.81. pg\_replication\_slots Columns**

Column Type	Description
slot_name name	A unique, cluster-wide identifier for the replication slot
plugin name	The base name of the shared object containing the output plugin this logical slot is using, or null for physical slots.
slot_type text	The slot type: <code>physical</code> or <code>logical</code>
datoid oid (references <a href="#">pg_database .oid</a> )	The OID of the database this slot is associated with, or null. Only logical slots have an associated database.
database name (references <a href="#">pg_database .datname</a> )	The name of the database this slot is associated with, or null. Only logical slots have an associated database.
temporary bool	True if this is a temporary replication slot. Temporary slots are not saved to disk and are automatically dropped on error or when the session has finished.
active bool	True if this slot is currently actively being used
active_pid int4	The process ID of the session using this slot if the slot is currently actively being used. NULL if inactive.
xmin xid	The oldest transaction that this slot needs the database to retain. <code>VACUUM</code> cannot remove tuples deleted by any later transaction.
catalog_xmin xid	The oldest transaction affecting the system catalogs that this slot needs the database to retain. <code>VACUUM</code> cannot remove catalog tuples deleted by any later transaction.
restart_lsn pg_lsn	The address (LSN) of oldest WAL which still might be required by the consumer of this slot and thus won't be automatically removed during checkpoints unless this LSN gets behind more than <a href="#">max_slot_wal_keep_size</a> from the current LSN. NULL if the LSN of this slot has never been reserved.

Column Type	Description
<code>confirmed_flush_lsn</code> <code>pg_lsn</code>	The address (LSN) up to which the logical slot's consumer has confirmed receiving data. Data older than this is not available anymore. NULL for physical slots.
<code>wal_status</code> <code>text</code>	Availability of WAL files claimed by this slot. Possible values are: <ul style="list-style-type: none"> <li><code>reserved</code> means that the claimed files are within <code>max_wal_size</code> .</li> <li><code>extended</code> means that <code>max_wal_size</code> is exceeded but the files are still retained, either by the replication slot or by <code>wal_keep_size</code> .</li> <li><code>unreserved</code> means that the slot no longer retains the required WAL files and some of them are to be removed at the next checkpoint. This state can return to <code>reserved</code> or <code>extended</code>.</li> <li><code>lost</code> means that some required WAL files have been removed and this slot is no longer usable.</li> </ul> The last two states are seen only when <code>max_slot_wal_keep_size</code> is non-negative. If <code>restart_lsn</code> is NULL, this field is null.
<code>safe_wal_size</code> <code>int8</code>	The number of bytes that can be written to WAL such that this slot is not in danger of getting in state "lost". It is NULL for lost slots, as well as if <code>max_slot_wal_keep_size</code> is -1.

## 49.81. pg\_roles

The view `pg_roles` provides access to information about database roles. This is simply a publicly readable view of `pg_authid` that blanks out the password field.

**Table 49.82. pg\_roles Columns**

Column Type	Description
<code>rolname</code> <code>name</code>	Role name
<code>rolsuper</code> <code>bool</code>	Role has superuser privileges
<code>rolinherit</code> <code>bool</code>	Role automatically inherits privileges of roles it is a member of
<code>rolcreaterole</code> <code>bool</code>	Role can create more roles
<code>rolcreatedb</code> <code>bool</code>	Role can create databases
<code>rolcanlogin</code> <code>bool</code>	Role can log in. That is, this role can be given as the initial session authorization identifier
<code>rolreplication</code> <code>bool</code>	Role is a replication role. A replication role can initiate replication connections and create and drop replication slots.
<code>rolconlimit</code> <code>int4</code>	For roles that can log in, this sets maximum number of concurrent connections this role can make. -1 means no limit.
<code>rolpassword</code> <code>text</code>	Not the password (always reads as <code>*****</code> )
<code>rolvaliduntil</code> <code>timestamptz</code>	

Column Type	Description
	Password expiry time (only used for password authentication); null if no expiration
rolbypassrls bool	Role bypasses every row level security policy, see <a href="#">Section 5.8</a> for more information.
rolconfig text []	Role-specific defaults for run-time configuration variables
oid oid (references <a href="#">pg_authid</a> .oid)	ID of role

## 49.82. pg\_rules

The view `pg_rules` provides access to useful information about query rewrite rules.

**Table 49.83. pg\_rules Columns**

Column Type	Description
schemaname name (references <a href="#">pg_namespace</a> .nspname)	Name of schema containing table
tablename name (references <a href="#">pg_class</a> .relname)	Name of table the rule is for
rulename name (references <a href="#">pg_rewrite</a> .rulename)	Name of rule
definition text	Rule definition (a reconstructed creation command)

The `pg_rules` view excludes the `ON SELECT` rules of views and materialized views; those can be seen in `pg_views` and `pg_matviews`.

## 49.83. pg\_seclabels

The view `pg_seclabels` provides information about security labels. It is an easier-to-query version of the `pg_seclabel` catalog.

**Table 49.84. pg\_seclabels Columns**

Column Type	Description
objoid oid (references any OID column)	The OID of the object this security label pertains to
classoid oid (references <a href="#">pg_class</a> .oid)	The OID of the system catalog this object appears in
objsubid int4	For a security label on a table column, this is the column number (the <code>objoid</code> and <code>classoid</code> refer to the table itself). For all other object types, this column is zero.
objtype text	The type of object to which this label applies, as text.
objnamespace oid (references <a href="#">pg_namespace</a> .oid)	The OID of the namespace for this object, if applicable; otherwise NULL.
objname text	The name of the object to which this label applies, as text.
provider text (references <a href="#">pg_seclabel</a> .provider)	

Column Type	Description
	The label provider associated with this label.
label text (references <a href="#">pg_seclabel</a> .label)	The security label applied to this object.

## 49.84. pg\_sequences

The view `pg_sequences` provides access to useful information about each sequence in the database.

**Table 49.85. pg\_sequences Columns**

Column Type	Description
schemaname name (references <a href="#">pg_namespace</a> .nspname)	Name of schema containing sequence
sequencename name (references <a href="#">pg_class</a> .relname)	Name of sequence
sequenceowner name (references <a href="#">pg_authid</a> .rolname)	Name of sequence's owner
data_type regtype (references <a href="#">pg_type</a> .oid)	Data type of the sequence
start_value int8	Start value of the sequence
min_value int8	Minimum value of the sequence
max_value int8	Maximum value of the sequence
increment_by int8	Increment value of the sequence
cycle bool	Whether the sequence cycles
cache_size int8	Cache size of the sequence
last_value int8	The last sequence value written to disk. If caching is used, this value can be greater than the last value handed out from the sequence. Null if the sequence has not been read from yet. Also, if the current user does not have <code>USAGE</code> or <code>SELECT</code> privilege on the sequence, the value is null.

## 49.85. pg\_settings

The view `pg_settings` provides access to run-time parameters of the server. It is essentially an alternative interface to the [SHOW](#) and [SET](#) commands. It also provides access to some facts about each parameter that are not directly available from `SHOW`, such as minimum and maximum values.

**Table 49.86. pg\_settings Columns**

Column Type	Description
name text	Run-time configuration parameter name
setting text	

<b>Column Type</b>	<b>Description</b>
	Current value of the parameter
unit text	Implicit unit of the parameter
category text	Logical group of the parameter
short_desc text	A brief description of the parameter
extra_desc text	Additional, more detailed, description of the parameter
context text	Context required to set the parameter's value (see below)
vartype text	Parameter type (bool, enum, integer, real, or string)
source text	Source of the current parameter value
min_val text	Minimum allowed value of the parameter (null for non-numeric values)
max_val text	Maximum allowed value of the parameter (null for non-numeric values)
enumvals text[]	Allowed values of an enum parameter (null for non-enum values)
boot_val text	Parameter value assumed at server startup if the parameter is not otherwise set
reset_val text	Value that RESET would reset the parameter to in the current session
sourcefile text	Configuration file the current value was set in (null for values set from sources other than configuration files, or when examined by a user who is neither a superuser or a member of <code>pg_read_all_settings</code> ); helpful when using <code>include</code> directives in configuration files
sourceline int4	Line number within the configuration file the current value was set at (null for values set from sources other than configuration files, or when examined by a user who is neither a superuser or a member of <code>pg_read_all_settings</code> ).
pending_restart bool	true if the value has been changed in the configuration file but needs a restart; or false otherwise.

There are several possible values of `context`. In order of decreasing difficulty of changing the setting, they are:

`internal`

These settings cannot be changed directly; they reflect internally determined values. Some of them may be adjustable by rebuilding the server with different configuration options, or by changing options supplied to `initdb`.

`postmaster`

These settings can only be applied when the server starts, so any change requires restarting the server. Values for these settings are typically stored in the `postgresql.conf` file, or passed on the

command line when starting the server. Of course, settings with any of the lower `context` types can also be set at server start time.

#### `sighup`

Changes to these settings can be made in `postgresql.conf` without restarting the server. Send a `SIGHUP` signal to the postmaster to cause it to re-read `postgresql.conf` and apply the changes. The postmaster will also forward the `SIGHUP` signal to its child processes so that they all pick up the new value.

#### `superuser-backend`

Changes to these settings can be made in `postgresql.conf` without restarting the server. They can also be set for a particular session in the connection request packet (for example, via libpq's `PGOPTIONS` environment variable), but only if the connecting user is a superuser. However, these settings never change in a session after it is started. If you change them in `postgresql.conf`, send a `SIGHUP` signal to the postmaster to cause it to re-read `postgresql.conf`. The new values will only affect subsequently-launched sessions.

#### `backend`

Changes to these settings can be made in `postgresql.conf` without restarting the server. They can also be set for a particular session in the connection request packet (for example, via libpq's `PGOPTIONS` environment variable); any user can make such a change for their session. However, these settings never change in a session after it is started. If you change them in `postgresql.conf`, send a `SIGHUP` signal to the postmaster to cause it to re-read `postgresql.conf`. The new values will only affect subsequently-launched sessions.

#### `superuser`

These settings can be set from `postgresql.conf`, or within a session via the `SET` command; but only superusers can change them via `SET`. Changes in `postgresql.conf` will affect existing sessions only if no session-local value has been established with `SET`.

#### `user`

These settings can be set from `postgresql.conf`, or within a session via the `SET` command. Any user is allowed to change their session-local value. Changes in `postgresql.conf` will affect existing sessions only if no session-local value has been established with `SET`.

See [Section 18.1](#) for more information about the various ways to change these parameters.

The `pg_settings` view cannot be inserted into or deleted from, but it can be updated. An `UPDATE` applied to a row of `pg_settings` is equivalent to executing the `SET` command on that named parameter. The change only affects the value used by the current session. If an `UPDATE` is issued within a transaction that is later aborted, the effects of the `UPDATE` command disappear when the transaction is rolled back. Once the surrounding transaction is committed, the effects will persist until the end of the session, unless overridden by another `UPDATE` or `SET`.

## 49.86. `pg_shadow`

The view `pg_shadow` exists for backwards compatibility: it emulates a catalog that existed in PostgreSQL before version 8.1. It shows properties of all roles that are marked as `rolcanlogin` in `pg_authid`.

The name stems from the fact that this table should not be readable by the public since it contains passwords. `pg_user` is a publicly readable view on `pg_shadow` that blanks out the password field.

**Table 49.87. `pg_shadow` Columns**

Column Type	Description
<code>username</code> name	(references <code>pg_authid</code> .rolname)

Column Type	Description
	User name
usesysid oid (references <code>pg_authid .oid</code> )	ID of this user
usecreatedb bool	User can create databases
usesuper bool	User is a superuser
userepl bool	User can initiate streaming replication and put the system in and out of backup mode.
usebypassrls bool	User bypasses every row level security policy, see <a href="#">Section 5.8</a> for more information.
passwd text	Password (possibly encrypted); null if none. See <code>pg_authid</code> for details of how encrypted passwords are stored.
valuntil timestamptz	Password expiry time (only used for password authentication)
useconfig text []	Session defaults for run-time configuration variables

## 49.87. `pg_shmem_allocations`

The `pg_shmem_allocations` view shows allocations made from the server's main shared memory segment. This includes both memory allocated by postgres itself and memory allocated by extensions using the mechanisms detailed in [Section 35.10.10](#).

Note that this view does not include memory allocated using the dynamic shared memory infrastructure.

**Table 49.88. `pg_shmem_allocations` Columns**

Column Type	Description
name text	The name of the shared memory allocation. NULL for unused memory and <code>&lt;anonymous&gt;</code> for anonymous allocations.
off int8	The offset at which the allocation starts. NULL for anonymous allocations, since details related to them are not known.
size int8	Size of the allocation
allocated_size int8	Size of the allocation including padding. For anonymous allocations, no information about padding is available, so the <code>size</code> and <code>allocated_size</code> columns will always be equal. Padding is not meaningful for free memory, so the columns will be equal in that case also.

Anonymous allocations are allocations that have been made with `ShmemAlloc()` directly, rather than via `ShmemInitStruct()` or `ShmemInitHash()`.

By default, the `pg_shmem_allocations` view can be read only by superusers.

## 49.88. `pg_stats`

The view `pg_stats` provides access to the information stored in the `pg_statistic` catalog. This view allows access only to rows of `pg_statistic` that correspond to tables the user has permission to read, and therefore it is safe to allow public read access to this view.

`pg_stats` is also designed to present the information in a more readable format than the underlying catalog — at the cost that its schema must be extended whenever new slot types are defined for `pg_statistic`.

**Table 49.89. `pg_stats` Columns**

Column Type	Description
<code>schemaname name</code> (references <code>pg_namespace .nspname</code> )	Name of schema containing table
<code>tablename name</code> (references <code>pg_class .relname</code> )	Name of table
<code>attname name</code> (references <code>pg_attribute .attname</code> )	Name of the column described by this row
<code>inherited bool</code>	If true, this row includes inheritance child columns, not just the values in the specified table
<code>null_frac float4</code>	Fraction of column entries that are null
<code>avg_width int4</code>	Average width in bytes of column's entries
<code>n_distinct float4</code>	If greater than zero, the estimated number of distinct values in the column. If less than zero, the negative of the number of distinct values divided by the number of rows. (The negated form is used when <code>ANALYZE</code> believes that the number of distinct values is likely to increase as the table grows; the positive form is used when the column seems to have a fixed number of possible values.) For example, -1 indicates a unique column in which the number of distinct values is the same as the number of rows.
<code>most_common_vals anyarray</code>	A list of the most common values in the column. (Null if no values seem to be more common than any others.)
<code>most_common_freqs float4[]</code>	A list of the frequencies of the most common values, i.e., number of occurrences of each divided by total number of rows. (Null when <code>most_common_vals</code> is.)
<code>histogram_bounds anyarray</code>	A list of values that divide the column's values into groups of approximately equal population. The values in <code>most_common_vals</code> , if present, are omitted from this histogram calculation. (This column is null if the column data type does not have a < operator or if the <code>most_common_vals</code> list accounts for the entire population.)
<code>correlation float4</code>	Statistical correlation between physical row ordering and logical ordering of the column values. This ranges from -1 to +1. When the value is near -1 or +1, an index scan on the column will be estimated to be cheaper than when it is near zero, due to reduction of random access to the disk. (This column is null if the column data type does not have a < operator.)
<code>most_common_elems anyarray</code>	A list of non-null element values most often appearing within values of the column. (Null for scalar types.)
<code>most_common_elem_freqs float4[]</code>	A list of the frequencies of the most common element values, i.e., the fraction of rows containing at least one instance of the given value. Two or three additional values follow the

Column Type	Description
	per-element frequencies; these are the minimum and maximum of the preceding per-element frequencies, and optionally the frequency of null elements. (Null when <code>most_common_elems</code> is.)
<code>elem_count_histogram float4[]</code>	A histogram of the counts of distinct non-null element values within the values of the column, followed by the average number of distinct non-null elements. (Null for scalar types.)

The maximum number of entries in the array fields can be controlled on a column-by-column basis using the `ALTER TABLE SET STATISTICS` command, or globally by setting the `default_statistics_target` run-time parameter.

## 49.89. `pg_stats_ext`

The view `pg_stats_ext` provides access to the information stored in the `pg_statistic_ext` and `pg_statistic_ext_data` catalogs. This view allows access only to rows of `pg_statistic_ext` and `pg_statistic_ext_data` that correspond to tables the user has permission to read, and therefore it is safe to allow public read access to this view.

`pg_stats_ext` is also designed to present the information in a more readable format than the underlying catalogs — at the cost that its schema must be extended whenever new types of extended statistics are added to `pg_statistic_ext`.

**Table 49.90. `pg_stats_ext` Columns**

Column Type	Description
<code>schemaname name (references <code>pg_namespace</code> .nspname)</code>	Name of schema containing table
<code>tablename name (references <code>pg_class</code> .relname)</code>	Name of table
<code>statistics_schemaname name (references <code>pg_namespace</code> .nspname)</code>	Name of schema containing extended statistic
<code>statistics_name name (references <code>pg_statistic_ext</code> .stxname)</code>	Name of extended statistics
<code>statistics_owner name (references <code>pg_authid</code> .rolname)</code>	Owner of the extended statistics
<code>attnames name[] (references <code>pg_attribute</code> .attname)</code>	Names of the columns the extended statistics is defined on
<code>kinds char[]</code>	Types of extended statistics enabled for this record
<code>n_distinct pg_ndistinct</code>	N-distinct counts for combinations of column values. If greater than zero, the estimated number of distinct values in the combination. If less than zero, the negative of the number of distinct values divided by the number of rows. (The negated form is used when <code>ANALYZE</code> believes that the number of distinct values is likely to increase as the table grows; the positive form is used when the column seems to have a fixed number of possible values.) For example, -1 indicates a unique combination of columns in which the number of distinct combinations is the same as the number of rows.
<code>dependencies pg_dependencies</code>	Functional dependency statistics
<code>most_common_vals text[]</code>	

Column Type	Description
	A list of the most common combinations of values in the columns. (Null if no combinations seem to be more common than any others.)
<code>most_common_val_nulls</code> <code>bool[]</code>	A list of NULL flags for the most common combinations of values. (Null when <code>most_common_vals</code> is.)
<code>most_common_freqs</code> <code>float8[]</code>	A list of the frequencies of the most common combinations, i.e., number of occurrences of each divided by total number of rows. (Null when <code>most_common_vals</code> is.)
<code>most_common_base_freqs</code> <code>float8[]</code>	A list of the base frequencies of the most common combinations, i.e., product of per-value frequencies. (Null when <code>most_common_vals</code> is.)

The maximum number of entries in the array fields can be controlled on a column-by-column basis using the `ALTER TABLE SET STATISTICS` command, or globally by setting the `default_statistics_target` runtime parameter.

## 49.90. `pg_tables`

The view `pg_tables` provides access to useful information about each table in the database.

**Table 49.91. `pg_tables` Columns**

Column Type	Description
<code>schemaname</code> <code>name</code> (references <code>pg_namespace</code> <code>.nspname</code> )	Name of schema containing table
<code>tablename</code> <code>name</code> (references <code>pg_class</code> <code>.relname</code> )	Name of table
<code>tableowner</code> <code>name</code> (references <code>pg_authid</code> <code>.rolname</code> )	Name of table's owner
<code>tablespace</code> <code>name</code> (references <code>pg_tablespace</code> <code>.spcname</code> )	Name of tablespace containing table (null if default for database)
<code>hasindexes</code> <code>bool</code> (references <code>pg_class</code> <code>.relhasindex</code> )	True if table has (or recently had) any indexes
<code>hasrules</code> <code>bool</code> (references <code>pg_class</code> <code>.relhasrules</code> )	True if table has (or once had) rules
<code>hastriggers</code> <code>bool</code> (references <code>pg_class</code> <code>.relhastriggers</code> )	True if table has (or once had) triggers
<code>rowsecurity</code> <code>bool</code> (references <code>pg_class</code> <code>.relrowsecurity</code> )	True if row security is enabled on the table

## 49.91. `pg_timezone_abbrevs`

The view `pg_timezone_abbrevs` provides a list of time zone abbreviations that are currently recognized by the datetime input routines. The contents of this view change when the `timezone_abbreviations` runtime parameter is modified.

**Table 49.92. `pg_timezone_abbrevs` Columns**

Column Type	Description
<code>abbrev</code> <code>text</code>	

Column Type	Description
	Time zone abbreviation
utc_offset interval	Offset from UTC (positive means east of Greenwich)
is_dst bool	True if this is a daylight-savings abbreviation

While most timezone abbreviations represent fixed offsets from UTC, there are some that have historically varied in value (see [Section B.4](#) for more information). In such cases this view presents their current meaning.

## 49.92. pg\_timezone\_names

The view `pg_timezone_names` provides a list of time zone names that are recognized by `SET TIMEZONE`, along with their associated abbreviations, UTC offsets, and daylight-savings status. (Technically, Postgres Pro does not use UTC because leap seconds are not handled.) Unlike the abbreviations shown in `pg_timezone_abbrevs`, many of these names imply a set of daylight-savings transition date rules. Therefore, the associated information changes across local DST boundaries. The displayed information is computed based on the current value of `CURRENT_TIMESTAMP`.

**Table 49.93. pg\_timezone\_names Columns**

Column Type	Description
name text	Time zone name
abbrev text	Time zone abbreviation
utc_offset interval	Offset from UTC (positive means east of Greenwich)
is_dst bool	True if currently observing daylight savings

## 49.93. pg\_user

The view `pg_user` provides access to information about database users. This is simply a publicly readable view of `pg_shadow` that blanks out the password field.

**Table 49.94. pg\_user Columns**

Column Type	Description
username name	User name
usesysid oid	ID of this user
usecreatedb bool	User can create databases
usesuper bool	User is a superuser
userepl bool	User can initiate streaming replication and put the system in and out of backup mode.

Column Type	Description
usebypassrls bool	User bypasses every row level security policy, see <a href="#">Section 5.8</a> for more information.
passwd text	Not the password (always reads as <code>*****</code> )
valuntil timestampz	Password expiry time (only used for password authentication)
useconfig text []	Session defaults for run-time configuration variables

## 49.94. pg\_user\_mappings

The view `pg_user_mappings` provides access to information about user mappings. This is essentially a publicly readable view of `pg_user_mapping` that leaves out the options field if the user has no rights to use it.

**Table 49.95. pg\_user\_mappings Columns**

Column Type	Description
umid oid (references <code>pg_user_mapping</code> .oid)	OID of the user mapping
srvid oid (references <code>pg_foreign_server</code> .oid)	The OID of the foreign server that contains this mapping
srvname name (references <code>pg_foreign_server</code> .srvname)	Name of the foreign server
umuser oid (references <code>pg_authid</code> .oid)	OID of the local role being mapped, 0 if the user mapping is public
username name	Name of the local user to be mapped
umoptions text []	User mapping specific options, as “keyword=value” strings

To protect password information stored as a user mapping option, the `umoptions` column will read as null unless one of the following applies:

- current user is the user being mapped, and owns the server or holds `USAGE` privilege on it
- current user is the server owner and mapping is for `PUBLIC`
- current user is a superuser

## 49.95. pg\_views

The view `pg_views` provides access to useful information about each view in the database.

**Table 49.96. pg\_views Columns**

Column Type	Description
schemaname name (references <code>pg_namespace</code> .nspname)	Name of schema containing view
viewname name (references <code>pg_class</code> .relname)	Name of view

<b>Column Type</b>	<b>Description</b>
viewowner name (references <code>pg_authid</code> .rolname)	Name of view's owner
definition text	View definition (a reconstructed <code>SELECT</code> query)

---

# Chapter 50. Frontend/Backend Protocol

Postgres Pro uses a message-based protocol for communication between frontends and backends (clients and servers). The protocol is supported over TCP/IP and also over Unix-domain sockets. Port number 5432 has been registered with IANA as the customary TCP port number for servers supporting this protocol, but in practice any non-privileged port number can be used.

This document describes version 3.0 of the protocol, implemented in PostgreSQL 7.4 and later. For descriptions of the earlier protocol versions, see previous releases of the PostgreSQL documentation. A single server can support multiple protocol versions. The initial startup-request message tells the server which protocol version the client is attempting to use. If the major version requested by the client is not supported by the server, the connection will be rejected (for example, this would occur if the client requested protocol version 4.0, which does not exist as of this writing). If the minor version requested by the client is not supported by the server (e.g., the client requests version 3.1, but the server supports only 3.0), the server may either reject the connection or may respond with a `NegotiateProtocolVersion` message containing the highest minor protocol version which it supports. The client may then choose either to continue with the connection using the specified protocol version or to abort the connection.

In order to serve multiple clients efficiently, the server launches a new “backend” process for each client. In the current implementation, a new child process is created immediately after an incoming connection is detected. This is transparent to the protocol, however. For purposes of the protocol, the terms “backend” and “server” are interchangeable; likewise “frontend” and “client” are interchangeable.

## 50.1. Overview

The protocol has separate phases for startup and normal operation. In the startup phase, the frontend opens a connection to the server and authenticates itself to the satisfaction of the server. (This might involve a single message, or multiple messages depending on the authentication method being used.) If all goes well, the server then sends status information to the frontend, and finally enters normal operation. Except for the initial startup-request message, this part of the protocol is driven by the server.

During normal operation, the frontend sends queries and other commands to the backend, and the backend sends back query results and other responses. There are a few cases (such as `NOTIFY`) wherein the backend will send unsolicited messages, but for the most part this portion of a session is driven by frontend requests.

Termination of the session is normally by frontend choice, but can be forced by the backend in certain cases. In any case, when the backend closes the connection, it will roll back any open (incomplete) transaction before exiting.

Within normal operation, SQL commands can be executed through either of two sub-protocols. In the “simple query” protocol, the frontend just sends a textual query string, which is parsed and immediately executed by the backend. In the “extended query” protocol, processing of queries is separated into multiple steps: parsing, binding of parameter values, and execution. This offers flexibility and performance benefits, at the cost of extra complexity.

Normal operation has additional sub-protocols for special operations such as `COPY`.

### 50.1.1. Messaging Overview

All communication is through a stream of messages. The first byte of a message identifies the message type, and the next four bytes specify the length of the rest of the message (this length count includes itself, but not the message-type byte). The remaining contents of the message are determined by the message type. For historical reasons, the very first message sent by the client (the startup message) has no initial message-type byte.

To avoid losing synchronization with the message stream, both servers and clients typically read an entire message into a buffer (using the byte count) before attempting to process its contents. This allows

easy recovery if an error is detected while processing the contents. In extreme situations (such as not having enough memory to buffer the message), the receiver can use the byte count to determine how much input to skip before it resumes reading messages.

Conversely, both servers and clients must take care never to send an incomplete message. This is commonly done by marshaling the entire message in a buffer before beginning to send it. If a communications failure occurs partway through sending or receiving a message, the only sensible response is to abandon the connection, since there is little hope of recovering message-boundary synchronization.

### 50.1.2. Extended Query Overview

In the extended-query protocol, execution of SQL commands is divided into multiple steps. The state retained between steps is represented by two types of objects: *prepared statements* and *portals*. A prepared statement represents the result of parsing and semantic analysis of a textual query string. A prepared statement is not in itself ready to execute, because it might lack specific values for *parameters*. A portal represents a ready-to-execute or already-partially-executed statement, with any missing parameter values filled in. (For `SELECT` statements, a portal is equivalent to an open cursor, but we choose to use a different term since cursors don't handle non-`SELECT` statements.)

The overall execution cycle consists of a *parse* step, which creates a prepared statement from a textual query string; a *bind* step, which creates a portal given a prepared statement and values for any needed parameters; and an *execute* step that runs a portal's query. In the case of a query that returns rows (`SELECT`, `SHOW`, etc), the execute step can be told to fetch only a limited number of rows, so that multiple execute steps might be needed to complete the operation.

The backend can keep track of multiple prepared statements and portals (but note that these exist only within a session, and are never shared across sessions). Existing prepared statements and portals are referenced by names assigned when they were created. In addition, an “unnamed” prepared statement and portal exist. Although these behave largely the same as named objects, operations on them are optimized for the case of executing a query only once and then discarding it, whereas operations on named objects are optimized on the expectation of multiple uses.

### 50.1.3. Formats and Format Codes

Data of a particular data type might be transmitted in any of several different *formats*. As of PostgreSQL 7.4 the only supported formats are “text” and “binary”, but the protocol makes provision for future extensions. The desired format for any value is specified by a *format code*. Clients can specify a format code for each transmitted parameter value and for each column of a query result. Text has format code zero, binary has format code one, and all other format codes are reserved for future definition.

The text representation of values is whatever strings are produced and accepted by the input/output conversion functions for the particular data type. In the transmitted representation, there is no trailing null character; the frontend must add one to received values if it wants to process them as C strings. (The text format does not allow embedded nulls, by the way.)

Binary representations for integers use network byte order (most significant byte first). For other data types consult the documentation or source code to learn about the binary representation. Keep in mind that binary representations for complex data types might change across server versions; the text format is usually the more portable choice.

## 50.2. Message Flow

This section describes the message flow and the semantics of each message type. (Details of the exact representation of each message appear in [Section 50.7](#).) There are several different sub-protocols depending on the state of the connection: start-up, query, function call, `COPY`, and termination. There are also special provisions for asynchronous operations (including notification responses and command cancellation), which can occur at any time after the start-up phase.

### 50.2.1. Start-up

To begin a session, a frontend opens a connection to the server and sends a startup message. This message includes the names of the user and of the database the user wants to connect to; it also identifies the particular protocol version to be used. (Optionally, the startup message can include additional settings for run-time parameters.) The server then uses this information and the contents of its configuration files (such as `pg_hba.conf`) to determine whether the connection is provisionally acceptable, and what additional authentication is required (if any).

The server then sends an appropriate authentication request message, to which the frontend must reply with an appropriate authentication response message (such as a password). For all authentication methods except GSSAPI, SSPI and SASL, there is at most one request and one response. In some methods, no response at all is needed from the frontend, and so no authentication request occurs. For GSSAPI, SSPI and SASL, multiple exchanges of packets may be needed to complete the authentication.

The authentication cycle ends with the server either rejecting the connection attempt (`ErrorResponse`), or sending `AuthenticationOk`.

The possible messages from the server in this phase are:

#### `ErrorResponse`

The connection attempt has been rejected. The server then immediately closes the connection.

#### `AuthenticationOk`

The authentication exchange is successfully completed.

#### `AuthenticationKerberosV5`

The frontend must now take part in a Kerberos V5 authentication dialog (not described here, part of the Kerberos specification) with the server. If this is successful, the server responds with an `AuthenticationOk`, otherwise it responds with an `ErrorResponse`. This is no longer supported.

#### `AuthenticationCleartextPassword`

The frontend must now send a `PasswordMessage` containing the password in clear-text form. If this is the correct password, the server responds with an `AuthenticationOk`, otherwise it responds with an `ErrorResponse`.

#### `AuthenticationMD5Password`

The frontend must now send a `PasswordMessage` containing the password (with user name) encrypted via MD5, then encrypted again using the 4-byte random salt specified in the `AuthenticationMD5Password` message. If this is the correct password, the server responds with an `AuthenticationOk`, otherwise it responds with an `ErrorResponse`. The actual `PasswordMessage` can be computed in SQL as `concat ('md5', md5 (concat (md5 (concat (password, username)), random-salt)))`. (Keep in mind the `md5()` function returns its result as a hex string.)

#### `AuthenticationSCMCredential`

This response is only possible for local Unix-domain connections on platforms that support SCM credential messages. The frontend must issue an SCM credential message and then send a single data byte. (The contents of the data byte are uninteresting; it's only used to ensure that the server waits long enough to receive the credential message.) If the credential is acceptable, the server responds with an `AuthenticationOk`, otherwise it responds with an `ErrorResponse`. (This message type is only issued by pre-9.1 servers. It may eventually be removed from the protocol specification.)

#### `AuthenticationGSS`

The frontend must now initiate a GSSAPI negotiation. The frontend will send a `GSSResponse` message with the first part of the GSSAPI data stream in response to this. If further messages are needed, the server will respond with `AuthenticationGSSContinue`.

### AuthenticationSSPI

The frontend must now initiate a SSPI negotiation. The frontend will send a GSSResponse with the first part of the SSPI data stream in response to this. If further messages are needed, the server will respond with AuthenticationGSSContinue.

### AuthenticationGSSContinue

This message contains the response data from the previous step of GSSAPI or SSPI negotiation (AuthenticationGSS, AuthenticationSSPI or a previous AuthenticationGSSContinue). If the GSSAPI or SSPI data in this message indicates more data is needed to complete the authentication, the frontend must send that data as another GSSResponse message. If GSSAPI or SSPI authentication is completed by this message, the server will next send AuthenticationOk to indicate successful authentication or ErrorResponse to indicate failure.

### AuthenticationSASL

The frontend must now initiate a SASL negotiation, using one of the SASL mechanisms listed in the message. The frontend will send a SASLInitialResponse with the name of the selected mechanism, and the first part of the SASL data stream in response to this. If further messages are needed, the server will respond with AuthenticationSASLContinue. See [Section 50.3](#) for details.

### AuthenticationSASLContinue

This message contains challenge data from the previous step of SASL negotiation (AuthenticationSASL, or a previous AuthenticationSASLContinue). The frontend must respond with a SASLResponse message.

### AuthenticationSASLFinal

SASL authentication has completed with additional mechanism-specific data for the client. The server will next send AuthenticationOk to indicate successful authentication, or an ErrorResponse to indicate failure. This message is sent only if the SASL mechanism specifies additional data to be sent from server to client at completion.

### NegotiateProtocolVersion

The server does not support the minor protocol version requested by the client, but does support an earlier version of the protocol; this message indicates the highest supported minor version. This message will also be sent if the client requested unsupported protocol options (i.e., beginning with `_pq_.`) in the startup packet. This message will be followed by an ErrorResponse or a message indicating the success or failure of authentication.

If the frontend does not support the authentication method requested by the server, then it should immediately close the connection.

After having received AuthenticationOk, the frontend must wait for further messages from the server. In this phase a backend process is being started, and the frontend is just an interested bystander. It is still possible for the startup attempt to fail (ErrorResponse) or the server to decline support for the requested minor protocol version (NegotiateProtocolVersion), but in the normal case the backend will send some ParameterStatus messages, BackendKeyData, and finally ReadyForQuery.

During this phase the backend will attempt to apply any additional run-time parameter settings that were given in the startup message. If successful, these values become session defaults. An error causes ErrorResponse and exit.

The possible messages from the backend in this phase are:

### BackendKeyData

This message provides secret-key data that the frontend must save if it wants to be able to issue cancel requests later. The frontend should not respond to this message, but should continue listening for a ReadyForQuery message.

### ParameterStatus

This message informs the frontend about the current (initial) setting of backend parameters, such as [client\\_encoding](#) or [DateStyle](#). The frontend can ignore this message, or record the settings for its future use; see [Section 50.2.6](#) for more details. The frontend should not respond to this message, but should continue listening for a ReadyForQuery message.

### ReadyForQuery

Start-up is completed. The frontend can now issue commands.

### ErrorResponse

Start-up failed. The connection is closed after sending this message.

### NoticeResponse

A warning message has been issued. The frontend should display the message but continue listening for ReadyForQuery or ErrorResponse.

The ReadyForQuery message is the same one that the backend will issue after each command cycle. Depending on the coding needs of the frontend, it is reasonable to consider ReadyForQuery as starting a command cycle, or to consider ReadyForQuery as ending the start-up phase and each subsequent command cycle.

## 50.2.2. Simple Query

A simple query cycle is initiated by the frontend sending a Query message to the backend. The message includes an SQL command (or commands) expressed as a text string. The backend then sends one or more response messages depending on the contents of the query command string, and finally a ReadyForQuery response message. ReadyForQuery informs the frontend that it can safely send a new command. (It is not actually necessary for the frontend to wait for ReadyForQuery before issuing another command, but the frontend must then take responsibility for figuring out what happens if the earlier command fails and already-issued later commands succeed.)

The possible response messages from the backend are:

### CommandComplete

An SQL command completed normally.

### CopyInResponse

The backend is ready to copy data from the frontend to a table; see [Section 50.2.5](#).

### CopyOutResponse

The backend is ready to copy data from a table to the frontend; see [Section 50.2.5](#).

### RowDescription

Indicates that rows are about to be returned in response to a `SELECT`, `FETCH`, etc query. The contents of this message describe the column layout of the rows. This will be followed by a DataRow message for each row being returned to the frontend.

### DataRow

One of the set of rows returned by a `SELECT`, `FETCH`, etc query.

### EmptyQueryResponse

An empty query string was recognized.

### ErrorResponse

An error has occurred.

## ReadyForQuery

Processing of the query string is complete. A separate message is sent to indicate this because the query string might contain multiple SQL commands. (CommandComplete marks the end of processing one SQL command, not the whole string.) ReadyForQuery will always be sent, whether processing terminates successfully or with an error.

## NoticeResponse

A warning message has been issued in relation to the query. Notices are in addition to other responses, i.e., the backend will continue processing the command.

The response to a `SELECT` query (or other queries that return row sets, such as `EXPLAIN` or `SHOW`) normally consists of `RowDescription`, zero or more `DataRow` messages, and then `CommandComplete`. `COPY` to or from the frontend invokes special protocol as described in [Section 50.2.5](#). All other query types normally produce only a `CommandComplete` message.

Since a query string could contain several queries (separated by semicolons), there might be several such response sequences before the backend finishes processing the query string. `ReadyForQuery` is issued when the entire string has been processed and the backend is ready to accept a new query string.

If a completely empty (no contents other than whitespace) query string is received, the response is `EmptyQueryResponse` followed by `ReadyForQuery`.

In the event of an error, `ErrorResponse` is issued followed by `ReadyForQuery`. All further processing of the query string is aborted by `ErrorResponse` (even if more queries remained in it). Note that this might occur partway through the sequence of messages generated by an individual query.

In simple Query mode, the format of retrieved values is always text, except when the given command is a `FETCH` from a cursor declared with the `BINARY` option. In that case, the retrieved values are in binary format. The format codes given in the `RowDescription` message tell which format is being used.

A frontend must be prepared to accept `ErrorResponse` and `NoticeResponse` messages whenever it is expecting any other type of message. See also [Section 50.2.6](#) concerning messages that the backend might generate due to outside events.

Recommended practice is to code frontends in a state-machine style that will accept any message type at any time that it could make sense, rather than wiring in assumptions about the exact sequence of messages.

### 50.2.2.1. Multiple Statements in a Simple Query

When a simple Query message contains more than one SQL statement (separated by semicolons), those statements are executed as a single transaction, unless explicit transaction control commands are included to force a different behavior. For example, if the message contains

```
INSERT INTO mytable VALUES (1);
SELECT 1/0;
INSERT INTO mytable VALUES (2);
```

then the divide-by-zero failure in the `SELECT` will force rollback of the first `INSERT`. Furthermore, because execution of the message is abandoned at the first error, the second `INSERT` is never attempted at all.

If instead the message contains

```
BEGIN;
INSERT INTO mytable VALUES (1);
COMMIT;
INSERT INTO mytable VALUES (2);
SELECT 1/0;
```

then the first `INSERT` is committed by the explicit `COMMIT` command. The second `INSERT` and the `SELECT` are still treated as a single transaction, so that the divide-by-zero failure will roll back the second `INSERT`, but not the first one.

This behavior is implemented by running the statements in a multi-statement Query message in an *implicit transaction block* unless there is some explicit transaction block for them to run in. The main difference between an implicit transaction block and a regular one is that an implicit block is closed automatically at the end of the Query message, either by an implicit commit if there was no error, or an implicit rollback if there was an error. This is similar to the implicit commit or rollback that happens for a statement executed by itself (when not in a transaction block).

If the session is already in a transaction block, as a result of a `BEGIN` in some previous message, then the Query message simply continues that transaction block, whether the message contains one statement or several. However, if the Query message contains a `COMMIT` or `ROLLBACK` closing the existing transaction block, then any following statements are executed in an implicit transaction block. Conversely, if a `BEGIN` appears in a multi-statement Query message, then it starts a regular transaction block that will only be terminated by an explicit `COMMIT` or `ROLLBACK`, whether that appears in this Query message or a later one. If the `BEGIN` follows some statements that were executed as an implicit transaction block, those statements are not immediately committed; in effect, they are retroactively included into the new regular transaction block.

A `COMMIT` or `ROLLBACK` appearing in an implicit transaction block is executed as normal, closing the implicit block; however, a warning will be issued since a `COMMIT` or `ROLLBACK` without a previous `BEGIN` might represent a mistake. If more statements follow, a new implicit transaction block will be started for them.

Savepoints are not allowed in an implicit transaction block, since they would conflict with the behavior of automatically closing the block upon any error.

Remember that, regardless of any transaction control commands that may be present, execution of the Query message stops at the first error. Thus for example given

```
BEGIN;  
SELECT 1/0;  
ROLLBACK;
```

in a single Query message, the session will be left inside a failed regular transaction block, since the `ROLLBACK` is not reached after the divide-by-zero error. Another `ROLLBACK` will be needed to restore the session to a usable state.

Another behavior of note is that initial lexical and syntactic analysis is done on the entire query string before any of it is executed. Thus simple errors (such as a misspelled keyword) in later statements can prevent execution of any of the statements. This is normally invisible to users since the statements would all roll back anyway when done as an implicit transaction block. However, it can be visible when attempting to do multiple transactions within a multi-statement Query. For instance, if a typo turned our previous example into

```
BEGIN;  
INSERT INTO mytable VALUES(1);  
COMMIT;  
INSERT INTO mytable VALUES(2);  
SELCT 1/0;
```

then none of the statements would get run, resulting in the visible difference that the first `INSERT` is not committed. Errors detected at semantic analysis or later, such as a misspelled table or column name, do not have this effect.

### 50.2.3. Extended Query

The extended query protocol breaks down the above-described simple query protocol into multiple steps. The results of preparatory steps can be re-used multiple times for improved efficiency. Furthermore, additional features are available, such as the possibility of supplying data values as separate parameters instead of having to insert them directly into a query string.

In the extended protocol, the frontend first sends a Parse message, which contains a textual query string, optionally some information about data types of parameter placeholders, and the name of a destination

prepared-statement object (an empty string selects the unnamed prepared statement). The response is either `ParseComplete` or `ErrorResponse`. Parameter data types can be specified by OID; if not given, the parser attempts to infer the data types in the same way as it would do for untyped literal string constants.

### Note

A parameter data type can be left unspecified by setting it to zero, or by making the array of parameter type OIDs shorter than the number of parameter symbols ( $\$n$ ) used in the query string. Another special case is that a parameter's type can be specified as `void` (that is, the OID of the `void` pseudo-type). This is meant to allow parameter symbols to be used for function parameters that are actually OUT parameters. Ordinarily there is no context in which a `void` parameter could be used, but if such a parameter symbol appears in a function's parameter list, it is effectively ignored. For example, a function call such as `foo($1,$2,$3,$4)` could match a function with two IN and two OUT arguments, if  $\$3$  and  $\$4$  are specified as having type `void`.

### Note

The query string contained in a `Parse` message cannot include more than one SQL statement; else a syntax error is reported. This restriction does not exist in the simple-query protocol, but it does exist in the extended protocol, because allowing prepared statements or portals to contain multiple commands would complicate the protocol unduly.

If successfully created, a named prepared-statement object lasts till the end of the current session, unless explicitly destroyed. An unnamed prepared statement lasts only until the next `Parse` statement specifying the unnamed statement as destination is issued. (Note that a simple `Query` message also destroys the unnamed statement.) Named prepared statements must be explicitly closed before they can be redefined by another `Parse` message, but this is not required for the unnamed statement. Named prepared statements can also be created and accessed at the SQL command level, using `PREPARE` and `EXECUTE`.

Once a prepared statement exists, it can be readied for execution using a `Bind` message. The `Bind` message gives the name of the source prepared statement (empty string denotes the unnamed prepared statement), the name of the destination portal (empty string denotes the unnamed portal), and the values to use for any parameter placeholders present in the prepared statement. The supplied parameter set must match those needed by the prepared statement. (If you declared any `void` parameters in the `Parse` message, pass `NULL` values for them in the `Bind` message.) `Bind` also specifies the format to use for any data returned by the query; the format can be specified overall, or per-column. The response is either `BindComplete` or `ErrorResponse`.

### Note

The choice between text and binary output is determined by the format codes given in `Bind`, regardless of the SQL command involved. The `BINARY` attribute in cursor declarations is irrelevant when using extended query protocol.

Query planning typically occurs when the `Bind` message is processed. If the prepared statement has no parameters, or is executed repeatedly, the server might save the created plan and re-use it during subsequent `Bind` messages for the same prepared statement. However, it will do so only if it finds that a generic plan can be created that is not much less efficient than a plan that depends on the specific parameter values supplied. This happens transparently so far as the protocol is concerned.

If successfully created, a named portal object lasts till the end of the current transaction, unless explicitly destroyed. An unnamed portal is destroyed at the end of the transaction, or as soon as the next `Bind` statement specifying the unnamed portal as destination is issued. (Note that a simple `Query` message also destroys the unnamed portal.) Named portals must be explicitly closed before they can be redefined

by another Bind message, but this is not required for the unnamed portal. Named portals can also be created and accessed at the SQL command level, using `DECLARE CURSOR` and `FETCH`.

Once a portal exists, it can be executed using an Execute message. The Execute message specifies the portal name (empty string denotes the unnamed portal) and a maximum result-row count (zero meaning “fetch all rows”). The result-row count is only meaningful for portals containing commands that return row sets; in other cases the command is always executed to completion, and the row count is ignored. The possible responses to Execute are the same as those described above for queries issued via simple query protocol, except that Execute doesn't cause ReadyForQuery or RowDescription to be issued.

If Execute terminates before completing the execution of a portal (due to reaching a nonzero result-row count), it will send a PortalSuspended message; the appearance of this message tells the frontend that another Execute should be issued against the same portal to complete the operation. The CommandComplete message indicating completion of the source SQL command is not sent until the portal's execution is completed. Therefore, an Execute phase is always terminated by the appearance of exactly one of these messages: CommandComplete, EmptyQueryResponse (if the portal was created from an empty query string), ErrorResponse, or PortalSuspended.

At completion of each series of extended-query messages, the frontend should issue a Sync message. This parameterless message causes the backend to close the current transaction if it's not inside a BEGIN/COMMIT transaction block (“close” meaning to commit if no error, or roll back if error). Then a ReadyForQuery response is issued. The purpose of Sync is to provide a resynchronization point for error recovery. When an error is detected while processing any extended-query message, the backend issues ErrorResponse, then reads and discards messages until a Sync is reached, then issues ReadyForQuery and returns to normal message processing. (But note that no skipping occurs if an error is detected *while* processing Sync — this ensures that there is one and only one ReadyForQuery sent for each Sync.)

### Note

Sync does not cause a transaction block opened with `BEGIN` to be closed. It is possible to detect this situation since the ReadyForQuery message includes transaction status information.

In addition to these fundamental, required operations, there are several optional operations that can be used with extended-query protocol.

The Describe message (portal variant) specifies the name of an existing portal (or an empty string for the unnamed portal). The response is a RowDescription message describing the rows that will be returned by executing the portal; or a NoData message if the portal does not contain a query that will return rows; or ErrorResponse if there is no such portal.

The Describe message (statement variant) specifies the name of an existing prepared statement (or an empty string for the unnamed prepared statement). The response is a ParameterDescription message describing the parameters needed by the statement, followed by a RowDescription message describing the rows that will be returned when the statement is eventually executed (or a NoData message if the statement will not return rows). ErrorResponse is issued if there is no such prepared statement. Note that since Bind has not yet been issued, the formats to be used for returned columns are not yet known to the backend; the format code fields in the RowDescription message will be zeroes in this case.

### Tip

In most scenarios the frontend should issue one or the other variant of Describe before issuing Execute, to ensure that it knows how to interpret the results it will get back.

The Close message closes an existing prepared statement or portal and releases resources. It is not an error to issue Close against a nonexistent statement or portal name. The response is normally CloseComplete, but could be ErrorResponse if some difficulty is encountered while releasing resources. Note that closing a prepared statement implicitly closes any open portals that were constructed from that statement.

The Flush message does not cause any specific output to be generated, but forces the backend to deliver any data pending in its output buffers. A Flush must be sent after any extended-query command except Sync, if the frontend wishes to examine the results of that command before issuing more commands. Without Flush, messages returned by the backend will be combined into the minimum possible number of packets to minimize network overhead.

### Note

The simple Query message is approximately equivalent to the series Parse, Bind, portal Describe, Execute, Close, Sync, using the unnamed prepared statement and portal objects and no parameters. One difference is that it will accept multiple SQL statements in the query string, automatically performing the bind/describe/execute sequence for each one in succession. Another difference is that it will not return ParseComplete, BindComplete, CloseComplete, or NoData messages.

## 50.2.4. Function Call

The Function Call sub-protocol allows the client to request a direct call of any function that exists in the database's `pg_proc` system catalog. The client must have execute permission for the function.

### Note

The Function Call sub-protocol is a legacy feature that is probably best avoided in new code. Similar results can be accomplished by setting up a prepared statement that does `SELECT function($1, ...)`. The Function Call cycle can then be replaced with Bind/Execute.

A Function Call cycle is initiated by the frontend sending a FunctionCall message to the backend. The backend then sends one or more response messages depending on the results of the function call, and finally a ReadyForQuery response message. ReadyForQuery informs the frontend that it can safely send a new query or function call.

The possible response messages from the backend are:

ErrorResponse

An error has occurred.

FunctionCallResponse

The function call was completed and returned the result given in the message. (Note that the Function Call protocol can only handle a single scalar result, not a row type or set of results.)

ReadyForQuery

Processing of the function call is complete. ReadyForQuery will always be sent, whether processing terminates successfully or with an error.

NoticeResponse

A warning message has been issued in relation to the function call. Notices are in addition to other responses, i.e., the backend will continue processing the command.

## 50.2.5. COPY Operations

The COPY command allows high-speed bulk data transfer to or from the server. Copy-in and copy-out operations each switch the connection into a distinct sub-protocol, which lasts until the operation is completed.

Copy-in mode (data transfer to the server) is initiated when the backend executes a `COPY FROM STDIN` SQL statement. The backend sends a CopyInResponse message to the frontend. The frontend should then

send zero or more CopyData messages, forming a stream of input data. (The message boundaries are not required to have anything to do with row boundaries, although that is often a reasonable choice.) The frontend can terminate the copy-in mode by sending either a CopyDone message (allowing successful termination) or a CopyFail message (which will cause the COPY SQL statement to fail with an error). The backend then reverts to the command-processing mode it was in before the COPY started, which will be either simple or extended query protocol. It will next send either CommandComplete (if successful) or ErrorResponse (if not).

In the event of a backend-detected error during copy-in mode (including receipt of a CopyFail message), the backend will issue an ErrorResponse message. If the COPY command was issued via an extended-query message, the backend will now discard frontend messages until a Sync message is received, then it will issue ReadyForQuery and return to normal processing. If the COPY command was issued in a simple Query message, the rest of that message is discarded and ReadyForQuery is issued. In either case, any subsequent CopyData, CopyDone, or CopyFail messages issued by the frontend will simply be dropped.

The backend will ignore Flush and Sync messages received during copy-in mode. Receipt of any other non-copy message type constitutes an error that will abort the copy-in state as described above. (The exception for Flush and Sync is for the convenience of client libraries that always send Flush or Sync after an Execute message, without checking whether the command to be executed is a COPY FROM STDIN.)

Copy-out mode (data transfer from the server) is initiated when the backend executes a COPY TO STDOUT SQL statement. The backend sends a CopyOutResponse message to the frontend, followed by zero or more CopyData messages (always one per row), followed by CopyDone. The backend then reverts to the command-processing mode it was in before the COPY started, and sends CommandComplete. The frontend cannot abort the transfer (except by closing the connection or issuing a Cancel request), but it can discard unwanted CopyData and CopyDone messages.

In the event of a backend-detected error during copy-out mode, the backend will issue an ErrorResponse message and revert to normal processing. The frontend should treat receipt of ErrorResponse as terminating the copy-out mode.

It is possible for NoticeResponse and ParameterStatus messages to be interspersed between CopyData messages; frontends must handle these cases, and should be prepared for other asynchronous message types as well (see [Section 50.2.6](#)). Otherwise, any message type other than CopyData or CopyDone may be treated as terminating copy-out mode.

There is another Copy-related mode called copy-both, which allows high-speed bulk data transfer to *and* from the server. Copy-both mode is initiated when a backend in walsender mode executes a START\_REPLICATION statement. The backend sends a CopyBothResponse message to the frontend. Both the backend and the frontend may then send CopyData messages until either end sends a CopyDone message. After the client sends a CopyDone message, the connection goes from copy-both mode to copy-out mode, and the client may not send any more CopyData messages. Similarly, when the server sends a CopyDone message, the connection goes into copy-in mode, and the server may not send any more CopyData messages. After both sides have sent a CopyDone message, the copy mode is terminated, and the backend reverts to the command-processing mode. In the event of a backend-detected error during copy-both mode, the backend will issue an ErrorResponse message, discard frontend messages until a Sync message is received, and then issue ReadyForQuery and return to normal processing. The frontend should treat receipt of ErrorResponse as terminating the copy in both directions; no CopyDone should be sent in this case. See [Section 50.4](#) for more information on the subprotocol transmitted over copy-both mode.

The CopyInResponse, CopyOutResponse and CopyBothResponse messages include fields that inform the frontend of the number of columns per row and the format codes being used for each column. (As of the present implementation, all columns in a given COPY operation will use the same format, but the message design does not assume this.)

## 50.2.6. Asynchronous Operations

There are several cases in which the backend will send messages that are not specifically prompted by the frontend's command stream. Frontends must be prepared to deal with these messages at any time,

even when not engaged in a query. At minimum, one should check for these cases before beginning to read a query response.

It is possible for NoticeResponse messages to be generated due to outside activity; for example, if the database administrator commands a “fast” database shutdown, the backend will send a NoticeResponse indicating this fact before closing the connection. Accordingly, frontends should always be prepared to accept and display NoticeResponse messages, even when the connection is nominally idle.

ParameterStatus messages will be generated whenever the active value changes for any of the parameters the backend believes the frontend should know about. Most commonly this occurs in response to a SET SQL command executed by the frontend, and this case is effectively synchronous — but it is also possible for parameter status changes to occur because the administrator changed a configuration file and then sent the SIGHUP signal to the server. Also, if a SET command is rolled back, an appropriate ParameterStatus message will be generated to report the current effective value.

At present there is a hard-wired set of parameters for which ParameterStatus will be generated: they are `server_version`, `server_encoding`, `client_encoding`, `application_name`, `is_superuser`, `session_authorization`, `DateStyle`, `IntervalStyle`, `TimeZone`, `integer_datetimes`, and `standard_conforming_strings`. (`server_encoding`, `TimeZone`, and `integer_datetimes` were not reported by releases before 8.0; `standard_conforming_strings` was not reported by releases before 8.1; `IntervalStyle` was not reported by releases before 8.4; `application_name` was not reported by releases before 9.0.) Note that `server_version`, `server_encoding` and `integer_datetimes` are pseudo-parameters that cannot change after startup. This set might change in the future, or even become configurable. Accordingly, a frontend should simply ignore ParameterStatus for parameters that it does not understand or care about.

If a frontend issues a LISTEN command, then the backend will send a NotificationResponse message (not to be confused with NoticeResponse!) whenever a NOTIFY command is executed for the same channel name.

### Note

At present, NotificationResponse can only be sent outside a transaction, and thus it will not occur in the middle of a command-response series, though it might occur just before ReadyForQuery. It is unwise to design frontend logic that assumes that, however. Good practice is to be able to accept NotificationResponse at any point in the protocol.

## 50.2.7. Canceling Requests in Progress

During the processing of a query, the frontend might request cancellation of the query. The cancel request is not sent directly on the open connection to the backend for reasons of implementation efficiency: we don't want to have the backend constantly checking for new input from the frontend during query processing. Cancel requests should be relatively infrequent, so we make them slightly cumbersome in order to avoid a penalty in the normal case.

To issue a cancel request, the frontend opens a new connection to the server and sends a CancelRequest message, rather than the StartupMessage message that would ordinarily be sent across a new connection. The server will process this request and then close the connection. For security reasons, no direct reply is made to the cancel request message.

A CancelRequest message will be ignored unless it contains the same key data (PID and secret key) passed to the frontend during connection start-up. If the request matches the PID and secret key for a currently executing backend, the processing of the current query is aborted. (In the existing implementation, this is done by sending a special signal to the backend process that is processing the query.)

The cancellation signal might or might not have any effect — for example, if it arrives after the backend has finished processing the query, then it will have no effect. If the cancellation is effective, it results in the current command being terminated early with an error message.

The upshot of all this is that for reasons of both security and efficiency, the frontend has no direct way to tell whether a cancel request has succeeded. It must continue to wait for the backend to respond to the query. Issuing a cancel simply improves the odds that the current query will finish soon, and improves the odds that it will fail with an error message instead of succeeding.

Since the cancel request is sent across a new connection to the server and not across the regular frontend/backend communication link, it is possible for the cancel request to be issued by any process, not just the frontend whose query is to be canceled. This might provide additional flexibility when building multiple-process applications. It also introduces a security risk, in that unauthorized persons might try to cancel queries. The security risk is addressed by requiring a dynamically generated secret key to be supplied in cancel requests.

### 50.2.8. Termination

The normal, graceful termination procedure is that the frontend sends a `Terminate` message and immediately closes the connection. On receipt of this message, the backend closes the connection and terminates.

In rare cases (such as an administrator-commanded database shutdown) the backend might disconnect without any frontend request to do so. In such cases the backend will attempt to send an error or notice message giving the reason for the disconnection before it closes the connection.

Other termination scenarios arise from various failure cases, such as core dump at one end or the other, loss of the communications link, loss of message-boundary synchronization, etc. If either frontend or backend sees an unexpected closure of the connection, it should clean up and terminate. The frontend has the option of launching a new backend by recontacting the server if it doesn't want to terminate itself. Closing the connection is also advisable if an unrecognizable message type is received, since this probably indicates loss of message-boundary sync.

For either normal or abnormal termination, any open transaction is rolled back, not committed. One should note however that if a frontend disconnects while a non-`SELECT` query is being processed, the backend will probably finish the query before noticing the disconnection. If the query is outside any transaction block (`BEGIN ... COMMIT` sequence) then its results might be committed before the disconnection is recognized.

### 50.2.9. SSL Session Encryption

If Postgres Pro was built with SSL support, frontend/backend communications can be encrypted using SSL. This provides communication security in environments where attackers might be able to capture the session traffic. For more information on encrypting Postgres Pro sessions with SSL, see [Section 17.9](#).

To initiate an SSL-encrypted connection, the frontend initially sends an `SSLRequest` message rather than a `StartupMessage`. The server then responds with a single byte containing `s` or `N`, indicating that it is willing or unwilling to perform SSL, respectively. The frontend might close the connection at this point if it is dissatisfied with the response. To continue after `s`, perform an SSL startup handshake (not described here, part of the SSL specification) with the server. If this is successful, continue with sending the usual `StartupMessage`. In this case the `StartupMessage` and all subsequent data will be SSL-encrypted. To continue after `N`, send the usual `StartupMessage` and proceed without encryption. (Alternatively, it is permissible to issue a `GSSENCRequest` message after an `N` response to try to use GSSAPI encryption instead of SSL.)

The frontend should also be prepared to handle an `ErrorMessage` response to `SSLRequest` from the server. This would only occur if the server predates the addition of SSL support to Postgres Pro. (Such servers are now very ancient, and likely do not exist in the wild anymore.) In this case the connection must be closed, but the frontend might choose to open a fresh connection and proceed without requesting SSL.

When SSL encryption can be performed, the server is expected to send only the single `s` byte and then wait for the frontend to initiate an SSL handshake. If additional bytes are available to read at this point, it likely means that a man-in-the-middle is attempting to perform a buffer-stuffing attack ([CVE-2021-23222](#)). Frontends should be coded either to read exactly one byte from the socket before

turning the socket over to their SSL library, or to treat it as a protocol violation if they find they have read additional bytes.

An initial `SSLRequest` can also be used in a connection that is being opened to send a `CancelRequest` message.

While the protocol itself does not provide a way for the server to force SSL encryption, the administrator can configure the server to reject unencrypted sessions as a byproduct of authentication checking.

### 50.2.10. GSSAPI Session Encryption

If Postgres Pro was built with GSSAPI support, frontend/backend communications can be encrypted using GSSAPI. This provides communication security in environments where attackers might be able to capture the session traffic. For more information on encrypting Postgres Pro sessions with GSSAPI, see [Section 17.10](#).

To initiate a GSSAPI-encrypted connection, the frontend initially sends a `GSSENCRequest` message rather than a `StartupMessage`. The server then responds with a single byte containing `G` or `N`, indicating that it is willing or unwilling to perform GSSAPI encryption, respectively. The frontend might close the connection at this point if it is dissatisfied with the response. To continue after `G`, using the GSSAPI C bindings as discussed in RFC2744 or equivalent, perform a GSSAPI initialization by calling `gss_init_sec_context()` in a loop and sending the result to the server, starting with an empty input and then with each result from the server, until it returns no output. When sending the results of `gss_init_sec_context()` to the server, prepend the length of the message as a four byte integer in network byte order. To continue after `N`, send the usual `StartupMessage` and proceed without encryption. (Alternatively, it is permissible to issue an `SSLRequest` message after an `N` response to try to use SSL encryption instead of GSSAPI.)

The frontend should also be prepared to handle an `ErrorMessage` response to `GSSENCRequest` from the server. This would only occur if the server predates the addition of GSSAPI encryption support to Postgres Pro. In this case the connection must be closed, but the frontend might choose to open a fresh connection and proceed without requesting GSSAPI encryption.

When GSSAPI encryption can be performed, the server is expected to send only the single `G` byte and then wait for the frontend to initiate a GSSAPI handshake. If additional bytes are available to read at this point, it likely means that a man-in-the-middle is attempting to perform a buffer-stuffing attack ([CVE-2021-23222](#)). Frontends should be coded either to read exactly one byte from the socket before turning the socket over to their GSSAPI library, or to treat it as a protocol violation if they find they have read additional bytes.

An initial `GSSENCRequest` can also be used in a connection that is being opened to send a `CancelRequest` message.

Once GSSAPI encryption has been successfully established, use `gss_wrap()` to encrypt the usual `StartupMessage` and all subsequent data, prepending the length of the result from `gss_wrap()` as a four byte integer in network byte order to the actual encrypted payload. Note that the server will only accept encrypted packets from the client which are less than 16kB; `gss_wrap_size_limit()` should be used by the client to determine the size of the unencrypted message which will fit within this limit and larger messages should be broken up into multiple `gss_wrap()` calls. Typical segments are 8kB of unencrypted data, resulting in encrypted packets of slightly larger than 8kB but well within the 16kB maximum. The server can be expected to not send encrypted packets of larger than 16kB to the client.

While the protocol itself does not provide a way for the server to force GSSAPI encryption, the administrator can configure the server to reject unencrypted sessions as a byproduct of authentication checking.

## 50.3. SASL Authentication

*SASL* is a framework for authentication in connection-oriented protocols. At the moment, Postgres Pro implements two SASL authentication mechanisms, SCRAM-SHA-256 and SCRAM-SHA-256-PLUS. More

might be added in the future. The below steps illustrate how SASL authentication is performed in general, while the next subsection gives more details on SCRAM-SHA-256 and SCRAM-SHA-256-PLUS.

### SASL Authentication Message Flow

1. To begin a SASL authentication exchange, the server sends an `AuthenticationSASL` message. It includes a list of SASL authentication mechanisms that the server can accept, in the server's preferred order.
2. The client selects one of the supported mechanisms from the list, and sends a `SASLInitialResponse` message to the server. The message includes the name of the selected mechanism, and an optional Initial Client Response, if the selected mechanism uses that.
3. One or more server-challenge and client-response message will follow. Each server-challenge is sent in an `AuthenticationSASLContinue` message, followed by a response from client in an `SASLResponse` message. The particulars of the messages are mechanism specific.
4. Finally, when the authentication exchange is completed successfully, the server sends an `AuthenticationSASLFinal` message, followed immediately by an `AuthenticationOk` message. The `AuthenticationSASLFinal` contains additional server-to-client data, whose content is particular to the selected authentication mechanism. If the authentication mechanism doesn't use additional data that's sent at completion, the `AuthenticationSASLFinal` message is not sent.

On error, the server can abort the authentication at any stage, and send an `ErrorMessage`.

## 50.3.1. SCRAM-SHA-256 Authentication

The implemented SASL mechanisms at the moment are `SCRAM-SHA-256` and its variant with channel binding `SCRAM-SHA-256-PLUS`. They are described in detail in RFC 7677 and RFC 5802.

When `SCRAM-SHA-256` is used in Postgres Pro, the server will ignore the user name that the client sends in the `client-first-message`. The user name that was already sent in the startup message is used instead. Postgres Pro supports multiple character encodings, while SCRAM dictates UTF-8 to be used for the user name, so it might be impossible to represent the Postgres Pro user name in UTF-8.

The SCRAM specification dictates that the password is also in UTF-8, and is processed with the `SASLprep` algorithm. Postgres Pro, however, does not require UTF-8 to be used for the password. When a user's password is set, it is processed with `SASLprep` as if it was in UTF-8, regardless of the actual encoding used. However, if it is not a legal UTF-8 byte sequence, or it contains UTF-8 byte sequences that are prohibited by the `SASLprep` algorithm, the raw password will be used without `SASLprep` processing, instead of throwing an error. This allows the password to be normalized when it is in UTF-8, but still allows a non-UTF-8 password to be used, and doesn't require the system to know which encoding the password is in.

*Channel binding* is supported in Postgres Pro builds with SSL support. The SASL mechanism name for SCRAM with channel binding is `SCRAM-SHA-256-PLUS`. The channel binding type used by Postgres Pro is `tls-server-end-point`.

In SCRAM without channel binding, the server chooses a random number that is transmitted to the client to be mixed with the user-supplied password in the transmitted password hash. While this prevents the password hash from being successfully retransmitted in a later session, it does not prevent a fake server between the real server and client from passing through the server's random value and successfully authenticating.

SCRAM with channel binding prevents such man-in-the-middle attacks by mixing the signature of the server's certificate into the transmitted password hash. While a fake server can retransmit the real server's certificate, it doesn't have access to the private key matching that certificate, and therefore cannot prove it is the owner, causing SSL connection failure.

### Example

1. The server sends an `AuthenticationSASL` message. It includes a list of SASL authentication mechanisms that the server can accept. This will be `SCRAM-SHA-256-PLUS` and `SCRAM-SHA-256` if the server is built with SSL support, or else just the latter.

2. The client responds by sending a `SASLInitialResponse` message, which indicates the chosen mechanism, `SCRAM-SHA-256` or `SCRAM-SHA-256-PLUS`. (A client is free to choose either mechanism, but for better security it should choose the channel-binding variant if it can support it.) In the Initial Client response field, the message contains the SCRAM `client-first-message`. The `client-first-message` also contains the channel binding type chosen by the client.
3. Server sends an `AuthenticationSASLContinue` message, with a SCRAM `server-first-message` as the content.
4. Client sends a `SASLResponse` message, with SCRAM `client-final-message` as the content.
5. Server sends an `AuthenticationSASLFinal` message, with the SCRAM `server-final-message`, followed immediately by an `AuthenticationOk` message.

## 50.4. Streaming Replication Protocol

To initiate streaming replication, the frontend sends the `replication` parameter in the startup message. A Boolean value of `true` (or `on`, `yes`, `1`) tells the backend to go into physical replication walsender mode, wherein a small set of replication commands, shown below, can be issued instead of SQL statements.

Passing `database` as the value for the `replication` parameter instructs the backend to go into logical replication walsender mode, connecting to the database specified in the `dbname` parameter. In logical replication walsender mode, the replication commands shown below as well as normal SQL commands can be issued.

In either physical replication or logical replication walsender mode, only the simple query protocol can be used.

For the purpose of testing replication commands, you can make a replication connection via `psql` or any other libpq-using tool with a connection string including the `replication` option, e.g.:

```
psql "dbname=postgres replication=database" -c "IDENTIFY_SYSTEM;"
```

However, it is often more useful to use [pg\\_receivewal](#) (for physical replication) or [pg\\_recvlogical](#) (for logical replication).

Replication commands are logged in the server log when [log\\_replication\\_commands](#) is enabled.

The commands accepted in replication mode are:

`IDENTIFY_SYSTEM`

Requests the server to identify itself. Server replies with a result set of a single row, containing four fields:

`systemid` (text)

The unique system identifier identifying the cluster. This can be used to check that the base backup used to initialize the standby came from the same cluster.

`timeline` (int4)

Current timeline ID. Also useful to check that the standby is consistent with the master.

`xlogpos` (text)

Current WAL flush location. Useful to get a known location in the write-ahead log where streaming can start.

`dbname` (text)

Database connected to or null.

`SHOW name`

Requests the server to send the current setting of a run-time parameter. This is similar to the SQL command [SHOW](#).

*name*

The name of a run-time parameter. Available parameters are documented in [Chapter 18](#).

`TIMELINE_HISTORY tli`

Requests the server to send over the timeline history file for timeline *tli*. Server replies with a result set of a single row, containing two fields. While the fields are labeled as `text` and `bytea`, they effectively return raw bytes, with no escaping or encoding conversion:

`filename (text)`

File name of the timeline history file, e.g., `00000002.history`.

`content (bytea)`

Contents of the timeline history file.

`CREATE_REPLICATION_SLOT slot_name [ TEMPORARY ] { PHYSICAL [ RESERVE_WAL ] | LOGICAL output_plugin [ EXPORT_SNAPSHOT | NOEXPORT_SNAPSHOT | USE_SNAPSHOT ] }`

Create a physical or logical replication slot. See [Section 25.2.6](#) for more about replication slots.

*slot\_name*

The name of the slot to create. Must be a valid replication slot name (see [Section 25.2.6.1](#)).

*output\_plugin*

The name of the output plugin used for logical decoding (see [Section 46.6](#)).

`TEMPORARY`

Specify that this replication slot is a temporary one. Temporary slots are not saved to disk and are automatically dropped on error or when the session has finished.

`RESERVE_WAL`

Specify that this physical replication slot reserves WAL immediately. Otherwise, WAL is only reserved upon connection from a streaming replication client.

`EXPORT_SNAPSHOT`

`NOEXPORT_SNAPSHOT`

`USE_SNAPSHOT`

Decides what to do with the snapshot created during logical slot initialization. `EXPORT_SNAPSHOT`, which is the default, will export the snapshot for use in other sessions. This option can't be used inside a transaction. `USE_SNAPSHOT` will use the snapshot for the current transaction executing the command. This option must be used in a transaction, and `CREATE_REPLICATION_SLOT` must be the first command run in that transaction. Finally, `NOEXPORT_SNAPSHOT` will just use the snapshot for logical decoding as normal but won't do anything else with it.

In response to this command, the server will send a one-row result set containing the following fields:

`slot_name (text)`

The name of the newly-created replication slot.

`consistent_point (text)`

The WAL location at which the slot became consistent. This is the earliest location from which streaming can start on this replication slot.

`snapshot_name (text)`

The identifier of the snapshot exported by the command. The snapshot is valid until a new command is executed on this connection or the replication connection is closed. Null if the created slot is physical.

`output_plugin` (text)

The name of the output plugin used by the newly-created replication slot. Null if the created slot is physical.

`START_REPLICATION` [ `SLOT` *slot\_name* ] [ `PHYSICAL` ] *XXX/XXX* [ `TIMELINE` *tli* ]

Instructs server to start streaming WAL, starting at WAL location *XXX/XXX*. If `TIMELINE` option is specified, streaming starts on timeline *tli*; otherwise, the server's current timeline is selected. The server can reply with an error, for example if the requested section of WAL has already been recycled. On success, the server responds with a `CopyBothResponse` message, and then starts to stream WAL to the frontend.

If a slot's name is provided via *slot\_name*, it will be updated as replication progresses so that the server knows which WAL segments, and if `hot_standby_feedback` is on which transactions, are still needed by the standby.

If the client requests a timeline that's not the latest but is part of the history of the server, the server will stream all the WAL on that timeline starting from the requested start point up to the point where the server switched to another timeline. If the client requests streaming at exactly the end of an old timeline, the server responds immediately with `CommandComplete` without entering `COPY` mode.

After streaming all the WAL on a timeline that is not the latest one, the server will end streaming by exiting the `COPY` mode. When the client acknowledges this by also exiting `COPY` mode, the server sends a result set with one row and two columns, indicating the next timeline in this server's history. The first column is the next timeline's ID (type `int8`), and the second column is the WAL location where the switch happened (type `text`). Usually, the switch position is the end of the WAL that was streamed, but there are corner cases where the server can send some WAL from the old timeline that it has not itself replayed before promoting. Finally, the server sends two `CommandComplete` messages (one that ends the `CopyData` and the other ends the `START_REPLICATION` itself), and is ready to accept a new command.

WAL data is sent as a series of `CopyData` messages. (This allows other information to be intermixed; in particular the server can send an `ErrorResponse` message if it encounters a failure after beginning to stream.) The payload of each `CopyData` message from server to the client contains a message of one of the following formats:

XLogData (B)

Byte1('w')

Identifies the message as WAL data.

Int64

The starting point of the WAL data in this message.

Int64

The current end of WAL on the server.

Int64

The server's system clock at the time of transmission, as microseconds since midnight on 2000-01-01.

Byten

A section of the WAL data stream.

A single WAL record is never split across two XLogData messages. When a WAL record crosses a WAL page boundary, and is therefore already split using continuation records, it can be split at the page boundary. In other words, the first main WAL record and its continuation records can be sent in different XLogData messages.

## Primary keepalive message (B)

Byte1('k')

Identifies the message as a sender keepalive.

Int64

The current end of WAL on the server.

Int64

The server's system clock at the time of transmission, as microseconds since midnight on 2000-01-01.

Byte1

1 means that the client should reply to this message as soon as possible, to avoid a timeout disconnect. 0 otherwise.

The receiving process can send replies back to the sender at any time, using one of the following message formats (also in the payload of a CopyData message):

## Standby status update (F)

Byte1('r')

Identifies the message as a receiver status update.

Int64

The location of the last WAL byte + 1 received and written to disk in the standby.

Int64

The location of the last WAL byte + 1 flushed to disk in the standby.

Int64

The location of the last WAL byte + 1 applied in the standby.

Int64

The client's system clock at the time of transmission, as microseconds since midnight on 2000-01-01.

Byte1

If 1, the client requests the server to reply to this message immediately. This can be used to ping the server, to test if the connection is still healthy.

## Hot Standby feedback message (F)

Byte1('h')

Identifies the message as a Hot Standby feedback message.

Int64

The client's system clock at the time of transmission, as microseconds since midnight on 2000-01-01.

Int32

The standby's current global xmin, excluding the catalog\_xmin from any replication slots. If both this value and the following catalog\_xmin are 0 this is treated as a notification that Hot Standby feedback will no longer be sent on this connection. Later non-zero messages may reinitiate the feedback mechanism.

Int32

The epoch of the global xmin xid on the standby.

Int32

The lowest catalog xmin of any replication slots on the standby. Set to 0 if no catalog xmin exists on the standby or if hot standby feedback is being disabled.

Int32

The epoch of the catalog xmin xid on the standby.

```
START_REPLICATION SLOT slot_name LOGICAL XXX/XXX [ ( option_name [ option_value ] [, ...] ) ]
```

Instructs server to start streaming WAL for logical replication, starting at WAL location *XXX/XXX*. The server can reply with an error, for example if the requested section of WAL has already been recycled. On success, server responds with a CopyBothResponse message, and then starts to stream WAL to the frontend.

The messages inside the CopyBothResponse messages are of the same format documented for START\_REPLICATION ... PHYSICAL, including two CommandComplete messages.

The output plugin associated with the selected slot is used to process the output for streaming.

*SLOT slot\_name*

The name of the slot to stream changes from. This parameter is required, and must correspond to an existing logical replication slot created with CREATE\_REPLICATION\_SLOT in LOGICAL mode.

*XXX/XXX*

The WAL location to begin streaming at.

*option\_name*

The name of an option passed to the slot's logical decoding plugin.

*option\_value*

Optional value, in the form of a string constant, associated with the specified option.

```
DROP_REPLICATION_SLOT slot_name [ WAIT ]
```

Drops a replication slot, freeing any reserved server-side resources. If the slot is a logical slot that was created in a database other than the database the walsender is connected to, this command fails.

*slot\_name*

The name of the slot to drop.

WAIT

This option causes the command to wait if the slot is active until it becomes inactive, instead of the default behavior of raising an error.

```
BASE_BACKUP [ LABEL 'label' ] [ PROGRESS ] [ FAST ] [ WAL ] [ NOWAIT ] [ MAX_RATE rate ] [ TABLESPACE_MAP ] [ NOVERIFY_CHECKSUMS ] [ MANIFEST manifest_option ] [ MANIFEST_CHECKSUMS checksum_algorithm ]
```

Instructs the server to start streaming a base backup. The system will automatically be put in backup mode before the backup is started, and taken out of it when the backup is complete. The following options are accepted:

LABEL '*label*'

Sets the label of the backup. If none is specified, a backup label of `base backup` will be used. The quoting rules for the label are the same as a standard SQL string with [standard\\_conforming\\_strings](#) turned on.

## PROGRESS

Request information required to generate a progress report. This will send back an approximate size in the header of each tablespace, which can be used to calculate how far along the stream is done. This is calculated by enumerating all the file sizes once before the transfer is even started, and might as such have a negative impact on the performance. In particular, it might take longer before the first data is streamed. Since the database files can change during the backup, the size is only approximate and might both grow and shrink between the time of approximation and the sending of the actual files.

## FAST

Request a fast checkpoint.

## WAL

Include the necessary WAL segments in the backup. This will include all the files between start and stop backup in the `pg_wal` directory of the base directory tar file.

## NOWAIT

By default, the backup will wait until the last required WAL segment has been archived, or emit a warning if log archiving is not enabled. Specifying `NOWAIT` disables both the waiting and the warning, leaving the client responsible for ensuring the required log is available.

MAX\_RATE *rate*

Limit (throttle) the maximum amount of data transferred from server to client per unit of time. The expected unit is kilobytes per second. If this option is specified, the value must either be equal to zero or it must fall within the range from 32 kB through 1 GB (inclusive). If zero is passed or the option is not specified, no restriction is imposed on the transfer.

## TABLESPACE\_MAP

Include information about symbolic links present in the directory `pg_tblspc` in a file named `tablespace_map`. The tablespace map file includes each symbolic link name as it exists in the directory `pg_tblspc/` and the full path of that symbolic link.

## NOVERIFY\_CHECKSUMS

By default, checksums are verified during a base backup if they are enabled. Specifying `NOVERIFY_CHECKSUMS` disables this verification.

MANIFEST *manifest\_option*

When this option is specified with a value of `yes` or `force-encode`, a backup manifest is created and sent along with the backup. The manifest is a list of every file present in the backup with the exception of any WAL files that may be included. It also stores the size, last modification time, and optionally a checksum for each file. A value of `force-encode` forces all filenames to be hex-encoded; otherwise, this type of encoding is performed only for files whose names are non-UTF8 octet sequences. `force-encode` is intended primarily for testing purposes, to be sure that clients which read the backup manifest can handle this case. For compatibility with previous releases, the default is `MANIFEST 'no'`.

MANIFEST\_CHECKSUMS *checksum\_algorithm*

Specifies the checksum algorithm that should be applied to each file included in the backup manifest. Currently, the available algorithms are `NONE`, `CRC32C`, `SHA224`, `SHA256`, `SHA384`, and `SHA512`. The default is `CRC32C`.

When the backup is started, the server will first send two ordinary result sets, followed by one or more CopyResponse results.

The first ordinary result set contains the starting position of the backup, in a single row with two columns. The first column contains the start position given in XLogRecPtr format, and the second column contains the corresponding timeline ID.

The second ordinary result set has one row for each tablespace. The fields in this row are:

`spcoid (oid)`

The OID of the tablespace, or null if it's the base directory.

`spclocation (text)`

The full path of the tablespace directory, or null if it's the base directory.

`size (int8)`

The approximate size of the tablespace, in kilobytes (1024 bytes), if progress report has been requested; otherwise it's null.

After the second regular result set, one or more CopyResponse results will be sent, one for the main data directory and one for each additional tablespace other than `pg_default` and `pg_global`. The data in the CopyResponse results will be a tar format (following the “ustar interchange format” specified in the POSIX 1003.1-2008 standard) dump of the tablespace contents, except that the two trailing blocks of zeroes specified in the standard are omitted. After the tar data is complete, and if a backup manifest was requested, another CopyResponse result is sent, containing the manifest data for the current base backup. In any case, a final ordinary result set will be sent, containing the WAL end position of the backup, in the same format as the start position.

The tar archive for the data directory and each tablespace will contain all files in the directories, regardless of whether they are Postgres Pro files or other files added to the same directory. The only excluded files are:

- `postmaster.pid`
- `postmaster.opts`
- `pg_internal.init` (found in multiple directories)
- Various temporary files and directories created during the operation of the Postgres Pro server, such as any file or directory beginning with `pgsql_tmp` and temporary relations.
- Unlogged relations, except for the init fork which is required to recreate the (empty) unlogged relation on recovery.
- `pg_wal`, including subdirectories. If the backup is run with WAL files included, a synthesized version of `pg_wal` will be included, but it will only contain the files necessary for the backup to work, not the rest of the contents.
- `pg_dynshmem`, `pg_notify`, `pg_replslot`, `pg_serial`, `pg_snapshots`, `pg_stat_tmp`, and `pg_subtrans` are copied as empty directories (even if they are symbolic links).
- Files other than regular files and directories, such as symbolic links (other than for the directories listed above) and special device files, are skipped. (Symbolic links in `pg_tblspc` are maintained.)

Owner, group, and file mode are set if the underlying file system on the server supports it.

## 50.5. Logical Streaming Replication Protocol

This section describes the logical replication protocol, which is the message flow started by the `START_REPLICATION SLOT slot_name LOGICAL` replication command.

The logical streaming replication protocol builds on the primitives of the physical streaming replication protocol.

### 50.5.1. Logical Streaming Replication Parameters

The logical replication `START_REPLICATION` command accepts following parameters:

proto\_version

Protocol version. Currently only version 1 is supported.

publication\_names

Comma separated list of publication names for which to subscribe (receive changes). The individual publication names are treated as standard objects names and can be quoted the same as needed.

## 50.5.2. Logical Replication Protocol Messages

The individual protocol messages are discussed in the following subsections. Individual messages are described in [Section 50.9](#).

All top-level protocol messages begin with a message type byte. While represented in code as a character, this is a signed byte with no associated encoding.

Since the streaming replication protocol supplies a message length there is no need for top-level protocol messages to embed a length in their header.

## 50.5.3. Logical Replication Protocol Message Flow

With the exception of the `START_REPLICATION` command and the replay progress messages, all information flows only from the backend to the frontend.

The logical replication protocol sends individual transactions one by one. This means that all messages between a pair of Begin and Commit messages belong to the same transaction.

Every sent transaction contains zero or more DML messages (Insert, Update, Delete). In case of a cascaded setup it can also contain Origin messages. The origin message indicates that the transaction originated on different replication node. Since a replication node in the scope of logical replication protocol can be pretty much anything, the only identifier is the origin name. It's downstream's responsibility to handle this as needed (if needed). The Origin message is always sent before any DML messages in the transaction.

Every DML message contains a relation OID, identifying the publisher's relation that was acted on. Before the first DML message for a given relation OID, a Relation message will be sent, describing the schema of that relation. Subsequently, a new Relation message will be sent if the relation's definition has changed since the last Relation message was sent for it. (The protocol assumes that the client is capable of remembering this metadata for as many relations as needed.)

Relation messages identify column types by their OIDs. In the case of a built-in type, it is assumed that the client can look up that type OID locally, so no additional data is needed. For a non-built-in type OID, a Type message will be sent before the Relation message, to provide the type name associated with that OID. Thus, a client that needs to specifically identify the types of relation columns should cache the contents of Type messages, and first consult that cache to see if the type OID is defined there. If not, look up the type OID locally.

## 50.6. Message Data Types

This section describes the base data types used in messages.

$\text{Int}_n(i)$

An  $n$ -bit integer in network byte order (most significant byte first). If  $i$  is specified it is the exact value that will appear, otherwise the value is variable. Eg. `Int16`, `Int32(42)`.

$\text{Int}_n[k]$

An array of  $k$   $n$ -bit integers, each in network byte order. The array length  $k$  is always determined by an earlier field in the message. Eg. `Int16[M]`.

**String(*s*)**

A null-terminated string (C-style string). There is no specific length limitation on strings. If *s* is specified it is the exact value that will appear, otherwise the value is variable. Eg. String, String("user").

**Note**

*There is no predefined limit on the length of a string that can be returned by the backend. Good coding strategy for a frontend is to use an expandable buffer so that anything that fits in memory can be accepted. If that's not feasible, read the full string and discard trailing characters that don't fit into your fixed-size buffer.*

**Byte<sub>*n*</sub>(*c*)**

Exactly *n* bytes. If the field width *n* is not a constant, it is always determinable from an earlier field in the message. If *c* is specified it is the exact value. Eg. Byte2, Byte1('\n').

## 50.7. Message Formats

This section describes the detailed format of each message. Each is marked to indicate that it can be sent by a frontend (F), a backend (B), or both (F & B). Notice that although each message includes a byte count at the beginning, the message format is defined so that the message end can be found without reference to the byte count. This aids validity checking. (The CopyData message is an exception, because it forms part of a data stream; the contents of any individual CopyData message cannot be interpretable on their own.)

**AuthenticationOk (B)**

Byte1('R')

Identifies the message as an authentication request.

Int32(8)

Length of message contents in bytes, including self.

Int32(0)

Specifies that the authentication was successful.

**AuthenticationKerberosV5 (B)**

Byte1('R')

Identifies the message as an authentication request.

Int32(8)

Length of message contents in bytes, including self.

Int32(2)

Specifies that Kerberos V5 authentication is required.

**AuthenticationCleartextPassword (B)**

Byte1('R')

Identifies the message as an authentication request.

Int32(8)

Length of message contents in bytes, including self.

Int32(3)

Specifies that a clear-text password is required.

AuthenticationMD5Password (B)

Byte1('R')

Identifies the message as an authentication request.

Int32(12)

Length of message contents in bytes, including self.

Int32(5)

Specifies that an MD5-encrypted password is required.

Byte4

The salt to use when encrypting the password.

AuthenticationSCMCredential (B)

Byte1('R')

Identifies the message as an authentication request.

Int32(8)

Length of message contents in bytes, including self.

Int32(6)

Specifies that an SCM credentials message is required.

AuthenticationGSS (B)

Byte1('R')

Identifies the message as an authentication request.

Int32(8)

Length of message contents in bytes, including self.

Int32(7)

Specifies that GSSAPI authentication is required.

AuthenticationSSPI (B)

Byte1('R')

Identifies the message as an authentication request.

Int32(8)

Length of message contents in bytes, including self.

Int32(9)

Specifies that SSPI authentication is required.

AuthenticationGSSContinue (B)

Byte1('R')

Identifies the message as an authentication request.

Int32

Length of message contents in bytes, including self.

Int32(8)

Specifies that this message contains GSSAPI or SSPI data.

Byte<sub>*n*</sub>

GSSAPI or SSPI authentication data.

AuthenticationSASL (B)

Byte1('R')

Identifies the message as an authentication request.

Int32

Length of message contents in bytes, including self.

Int32(10)

Specifies that SASL authentication is required.

The message body is a list of SASL authentication mechanisms, in the server's order of preference. A zero byte is required as terminator after the last authentication mechanism name. For each mechanism, there is the following:

String

Name of a SASL authentication mechanism.

AuthenticationSASLContinue (B)

Byte1('R')

Identifies the message as an authentication request.

Int32

Length of message contents in bytes, including self.

Int32(11)

Specifies that this message contains a SASL challenge.

Byte<sub>*n*</sub>

SASL data, specific to the SASL mechanism being used.

AuthenticationSASLFinal (B)

Byte1('R')

Identifies the message as an authentication request.

Int32

Length of message contents in bytes, including self.

Int32(12)

Specifies that SASL authentication has completed.

Byte<sub>*n*</sub>

SASL outcome "additional data", specific to the SASL mechanism being used.

## BackendKeyData (B)

Byte1('K')

Identifies the message as cancellation key data. The frontend must save these values if it wishes to be able to issue CancelRequest messages later.

Int32(12)

Length of message contents in bytes, including self.

Int32

The process ID of this backend.

Int32

The secret key of this backend.

## Bind (F)

Byte1('B')

Identifies the message as a Bind command.

Int32

Length of message contents in bytes, including self.

String

The name of the destination portal (an empty string selects the unnamed portal).

String

The name of the source prepared statement (an empty string selects the unnamed prepared statement).

Int16

The number of parameter format codes that follow (denoted  $c$  below). This can be zero to indicate that there are no parameters or that the parameters all use the default format (text); or one, in which case the specified format code is applied to all parameters; or it can equal the actual number of parameters.

Int16[ $c$ ]

The parameter format codes. Each must presently be zero (text) or one (binary).

Int16

The number of parameter values that follow (possibly zero). This must match the number of parameters needed by the query.

Next, the following pair of fields appear for each parameter:

Int32

The length of the parameter value, in bytes (this count does not include itself). Can be zero. As a special case, -1 indicates a NULL parameter value. No value bytes follow in the NULL case.

Byte $n$ 

The value of the parameter, in the format indicated by the associated format code.  $n$  is the above length.

After the last parameter, the following fields appear:

**Int16**

The number of result-column format codes that follow (denoted  $R$  below). This can be zero to indicate that there are no result columns or that the result columns should all use the default format (text); or one, in which case the specified format code is applied to all result columns (if any); or it can equal the actual number of result columns of the query.

**Int16[ $R$ ]**

The result-column format codes. Each must presently be zero (text) or one (binary).

**BindComplete (B)****Byte1('2')**

Identifies the message as a Bind-complete indicator.

**Int32(4)**

Length of message contents in bytes, including self.

**CancelRequest (F)****Int32(16)**

Length of message contents in bytes, including self.

**Int32(80877102)**

The cancel request code. The value is chosen to contain 1234 in the most significant 16 bits, and 5678 in the least significant 16 bits. (To avoid confusion, this code must not be the same as any protocol version number.)

**Int32**

The process ID of the target backend.

**Int32**

The secret key for the target backend.

**Close (F)****Byte1('C')**

Identifies the message as a Close command.

**Int32**

Length of message contents in bytes, including self.

**Byte1**

'S' to close a prepared statement; or 'P' to close a portal.

**String**

The name of the prepared statement or portal to close (an empty string selects the unnamed prepared statement or portal).

**CloseComplete (B)****Byte1('3')**

Identifies the message as a Close-complete indicator.

**Int32(4)**

Length of message contents in bytes, including self.

**CommandComplete (B)**

Byte1('C')

Identifies the message as a command-completed response.

Int32

Length of message contents in bytes, including self.

String

The command tag. This is usually a single word that identifies which SQL command was completed.

For an `INSERT` command, the tag is `INSERT oid rows`, where `rows` is the number of rows inserted. `oid` used to be the object ID of the inserted row if `rows` was 1 and the target table had OIDs, but OIDs system columns are not supported anymore; therefore `oid` is always 0.

For a `DELETE` command, the tag is `DELETE rows` where `rows` is the number of rows deleted.

For an `UPDATE` command, the tag is `UPDATE rows` where `rows` is the number of rows updated.

For a `SELECT` or `CREATE TABLE AS` command, the tag is `SELECT rows` where `rows` is the number of rows retrieved.

For a `MOVE` command, the tag is `MOVE rows` where `rows` is the number of rows the cursor's position has been changed by.

For a `FETCH` command, the tag is `FETCH rows` where `rows` is the number of rows that have been retrieved from the cursor.

For a `COPY` command, the tag is `COPY rows` where `rows` is the number of rows copied. (Note: the row count appears only in PostgreSQL 8.2 and later.)

**CopyData (F & B)**

Byte1('d')

Identifies the message as `COPY` data.

Int32

Length of message contents in bytes, including self.

Byten

Data that forms part of a `COPY` data stream. Messages sent from the backend will always correspond to single data rows, but messages sent by frontends might divide the data stream arbitrarily.

**CopyDone (F & B)**

Byte1('c')

Identifies the message as a `COPY`-complete indicator.

Int32(4)

Length of message contents in bytes, including self.

**CopyFail (F)**

Byte1('f')

Identifies the message as a `COPY`-failure indicator.

Int32

Length of message contents in bytes, including self.

String

An error message to report as the cause of failure.

CopyInResponse (B)

Byte1('G')

Identifies the message as a Start Copy In response. The frontend must now send copy-in data (if not prepared to do so, send a CopyFail message).

Int32

Length of message contents in bytes, including self.

Int8

0 indicates the overall COPY format is textual (rows separated by newlines, columns separated by separator characters, etc). 1 indicates the overall copy format is binary (similar to DataRow format). See [COPY](#) for more information.

Int16

The number of columns in the data to be copied (denoted  $N$  below).

Int16[ $N$ ]

The format codes to be used for each column. Each must presently be zero (text) or one (binary). All must be zero if the overall copy format is textual.

CopyOutResponse (B)

Byte1('H')

Identifies the message as a Start Copy Out response. This message will be followed by copy-out data.

Int32

Length of message contents in bytes, including self.

Int8

0 indicates the overall COPY format is textual (rows separated by newlines, columns separated by separator characters, etc). 1 indicates the overall copy format is binary (similar to DataRow format). See [COPY](#) for more information.

Int16

The number of columns in the data to be copied (denoted  $N$  below).

Int16[ $N$ ]

The format codes to be used for each column. Each must presently be zero (text) or one (binary). All must be zero if the overall copy format is textual.

CopyBothResponse (B)

Byte1('W')

Identifies the message as a Start Copy Both response. This message is used only for Streaming Replication.

Int32

Length of message contents in bytes, including self.

**Int8**

0 indicates the overall `COPY` format is textual (rows separated by newlines, columns separated by separator characters, etc). 1 indicates the overall copy format is binary (similar to `DataRow` format). See [COPY](#) for more information.

**Int16**

The number of columns in the data to be copied (denoted  $N$  below).

**Int16[ $N$ ]**

The format codes to be used for each column. Each must presently be zero (text) or one (binary). All must be zero if the overall copy format is textual.

**DataRow (B)****Byte1('D')**

Identifies the message as a data row.

**Int32**

Length of message contents in bytes, including self.

**Int16**

The number of column values that follow (possibly zero).

Next, the following pair of fields appear for each column:

**Int32**

The length of the column value, in bytes (this count does not include itself). Can be zero. As a special case, -1 indicates a NULL column value. No value bytes follow in the NULL case.

**Byte $n$** 

The value of the column, in the format indicated by the associated format code.  $n$  is the above length.

**Describe (F)****Byte1('D')**

Identifies the message as a Describe command.

**Int32**

Length of message contents in bytes, including self.

**Byte1**

'S' to describe a prepared statement; or 'P' to describe a portal.

**String**

The name of the prepared statement or portal to describe (an empty string selects the unnamed prepared statement or portal).

**EmptyQueryResponse (B)****Byte1('I')**

Identifies the message as a response to an empty query string. (This substitutes for `CommandComplete`.)

**Int32(4)**

Length of message contents in bytes, including self.

## ErrorResponse (B)

Byte1('E')

Identifies the message as an error.

Int32

Length of message contents in bytes, including self.

The message body consists of one or more identified fields, followed by a zero byte as a terminator. Fields can appear in any order. For each field there is the following:

Byte1

A code identifying the field type; if zero, this is the message terminator and no string follows. The presently defined field types are listed in [Section 50.8](#). Since more field types might be added in future, frontends should silently ignore fields of unrecognized type.

String

The field value.

## Execute (F)

Byte1('E')

Identifies the message as an Execute command.

Int32

Length of message contents in bytes, including self.

String

The name of the portal to execute (an empty string selects the unnamed portal).

Int32

Maximum number of rows to return, if portal contains a query that returns rows (ignored otherwise). Zero denotes “no limit”.

## Flush (F)

Byte1('H')

Identifies the message as a Flush command.

Int32(4)

Length of message contents in bytes, including self.

## FunctionCall (F)

Byte1('F')

Identifies the message as a function call.

Int32

Length of message contents in bytes, including self.

Int32

Specifies the object ID of the function to call.

Int16

The number of argument format codes that follow (denoted *c* below). This can be zero to indicate that there are no arguments or that the arguments all use the default format (text); or one, in

which case the specified format code is applied to all arguments; or it can equal the actual number of arguments.

Int16[c]

The argument format codes. Each must presently be zero (text) or one (binary).

Int16

Specifies the number of arguments being supplied to the function.

Next, the following pair of fields appear for each argument:

Int32

The length of the argument value, in bytes (this count does not include itself). Can be zero. As a special case, -1 indicates a NULL argument value. No value bytes follow in the NULL case.

Byte<sub>n</sub>

The value of the argument, in the format indicated by the associated format code. *n* is the above length.

After the last argument, the following field appears:

Int16

The format code for the function result. Must presently be zero (text) or one (binary).

FunctionCallResponse (B)

Byte1('V')

Identifies the message as a function call result.

Int32

Length of message contents in bytes, including self.

Int32

The length of the function result value, in bytes (this count does not include itself). Can be zero. As a special case, -1 indicates a NULL function result. No value bytes follow in the NULL case.

Byte<sub>n</sub>

The value of the function result, in the format indicated by the associated format code. *n* is the above length.

GSSResponse (F)

Byte1('p')

Identifies the message as a GSSAPI or SSPI response. Note that this is also used for SASL and password response messages. The exact message type can be deduced from the context.

Int32

Length of message contents in bytes, including self.

Byte<sub>n</sub>

GSSAPI/SSPI specific message data.

NegotiateProtocolVersion (B)

Byte1('v')

Identifies the message as a protocol version negotiation message.

Int32

Length of message contents in bytes, including self.

Int32

Newest minor protocol version supported by the server for the major protocol version requested by the client.

Int32

Number of protocol options not recognized by the server.

Then, for protocol option not recognized by the server, there is the following:

String

The option name.

NoData (B)

Byte1('n')

Identifies the message as a no-data indicator.

Int32(4)

Length of message contents in bytes, including self.

NoticeResponse (B)

Byte1('N')

Identifies the message as a notice.

Int32

Length of message contents in bytes, including self.

The message body consists of one or more identified fields, followed by a zero byte as a terminator. Fields can appear in any order. For each field there is the following:

Byte1

A code identifying the field type; if zero, this is the message terminator and no string follows. The presently defined field types are listed in [Section 50.8](#). Since more field types might be added in future, frontends should silently ignore fields of unrecognized type.

String

The field value.

NotificationResponse (B)

Byte1('A')

Identifies the message as a notification response.

Int32

Length of message contents in bytes, including self.

Int32

The process ID of the notifying backend process.

String

The name of the channel that the notify has been raised on.

String

The “payload” string passed from the notifying process.

ParameterDescription (B)

Byte1('t')

Identifies the message as a parameter description.

Int32

Length of message contents in bytes, including self.

Int16

The number of parameters used by the statement (can be zero).

Then, for each parameter, there is the following:

Int32

Specifies the object ID of the parameter data type.

ParameterStatus (B)

Byte1('S')

Identifies the message as a run-time parameter status report.

Int32

Length of message contents in bytes, including self.

String

The name of the run-time parameter being reported.

String

The current value of the parameter.

Parse (F)

Byte1('P')

Identifies the message as a Parse command.

Int32

Length of message contents in bytes, including self.

String

The name of the destination prepared statement (an empty string selects the unnamed prepared statement).

String

The query string to be parsed.

Int16

The number of parameter data types specified (can be zero). Note that this is not an indication of the number of parameters that might appear in the query string, only the number that the frontend wants to prespecify types for.

Then, for each parameter, there is the following:

Int32

Specifies the object ID of the parameter data type. Placing a zero here is equivalent to leaving the type unspecified.

ParseComplete (B)

Byte1('1')

Identifies the message as a Parse-complete indicator.

Int32(4)

Length of message contents in bytes, including self.

PasswordMessage (F)

Byte1('p')

Identifies the message as a password response. Note that this is also used for GSSAPI, SSPI and SASL response messages. The exact message type can be deduced from the context.

Int32

Length of message contents in bytes, including self.

String

The password (encrypted, if requested).

PortalSuspended (B)

Byte1('s')

Identifies the message as a portal-suspended indicator. Note this only appears if an Execute message's row-count limit was reached.

Int32(4)

Length of message contents in bytes, including self.

Query (F)

Byte1('Q')

Identifies the message as a simple query.

Int32

Length of message contents in bytes, including self.

String

The query string itself.

ReadyForQuery (B)

Byte1('Z')

Identifies the message type. ReadyForQuery is sent whenever the backend is ready for a new query cycle.

Int32(5)

Length of message contents in bytes, including self.

Byte1

Current backend transaction status indicator. Possible values are 'I' if idle (not in a transaction block); 'T' if in a transaction block; or 'E' if in a failed transaction block (queries will be rejected until block is ended).

## RowDescription (B)

Byte1('T')

Identifies the message as a row description.

Int32

Length of message contents in bytes, including self.

Int16

Specifies the number of fields in a row (can be zero).

Then, for each field, there is the following:

String

The field name.

Int32

If the field can be identified as a column of a specific table, the object ID of the table; otherwise zero.

Int16

If the field can be identified as a column of a specific table, the attribute number of the column; otherwise zero.

Int32

The object ID of the field's data type.

Int16

The data type size (see `pg_type.typelen`). Note that negative values denote variable-width types.

Int32

The type modifier (see `pg_attribute.atttypmod`). The meaning of the modifier is type-specific.

Int16

The format code being used for the field. Currently will be zero (text) or one (binary). In a RowDescription returned from the statement variant of Describe, the format code is not yet known and will always be zero.

## SASLInitialResponse (F)

Byte1('p')

Identifies the message as an initial SASL response. Note that this is also used for GSSAPI, SSPI and password response messages. The exact message type is deduced from the context.

Int32

Length of message contents in bytes, including self.

String

Name of the SASL authentication mechanism that the client selected.

Int32

Length of SASL mechanism specific "Initial Client Response" that follows, or -1 if there is no Initial Response.

Byte<sub>n</sub>

SASL mechanism specific "Initial Response".

SASLResponse (F)

Byte1('p')

Identifies the message as a SASL response. Note that this is also used for GSSAPI, SSPI and password response messages. The exact message type can be deduced from the context.

Int32

Length of message contents in bytes, including self.

Byte<sub>n</sub>

SASL mechanism specific message data.

SSLRequest (F)

Int32(8)

Length of message contents in bytes, including self.

Int32(80877103)

The SSL request code. The value is chosen to contain 1234 in the most significant 16 bits, and 5679 in the least significant 16 bits. (To avoid confusion, this code must not be the same as any protocol version number.)

GSSENCRequest (F)

Int32(8)

Length of message contents in bytes, including self.

Int32(80877104)

The GSSAPI Encryption request code. The value is chosen to contain 1234 in the most significant 16 bits, and 5680 in the least significant 16 bits. (To avoid confusion, this code must not be the same as any protocol version number.)

StartupMessage (F)

Int32

Length of message contents in bytes, including self.

Int32(196608)

The protocol version number. The most significant 16 bits are the major version number (3 for the protocol described here). The least significant 16 bits are the minor version number (0 for the protocol described here).

The protocol version number is followed by one or more pairs of parameter name and value strings. A zero byte is required as a terminator after the last name/value pair. Parameters can appear in any order. `user` is required, others are optional. Each parameter is specified as:

String

The parameter name. Currently recognized names are:

`user`

The database user name to connect as. Required; there is no default.

`database`

The database to connect to. Defaults to the user name.

`options`

Command-line arguments for the backend. (This is deprecated in favor of setting individual run-time parameters.) Spaces within this string are considered to separate arguments, unless escaped with a backslash (`\`); write `\\` to represent a literal backslash.

`replication`

Used to connect in streaming replication mode, where a small set of replication commands can be issued instead of SQL statements. Value can be `true`, `false`, or `database`, and the default is `false`. See [Section 50.4](#) for details.

In addition to the above, other parameters may be listed. Parameter names beginning with `_pq_.` are reserved for use as protocol extensions, while others are treated as run-time parameters to be set at backend start time. Such settings will be applied during backend start (after parsing the command-line arguments if any) and will act as session defaults.

## String

The parameter value.

## Sync (F)

## Byte1('S')

Identifies the message as a Sync command.

## Int32(4)

Length of message contents in bytes, including self.

## Terminate (F)

## Byte1('X')

Identifies the message as a termination.

## Int32(4)

Length of message contents in bytes, including self.

## 50.8. Error and Notice Message Fields

This section describes the fields that can appear in `ErrorResponse` and `NoticeResponse` messages. Each field type has a single-byte identification token. Note that any given field type should appear at most once per message.

## S

**Severity:** the field contents are `ERROR`, `FATAL`, or `PANIC` (in an error message), or `WARNING`, `NOTICE`, `DEBUG`, `INFO`, or `LOG` (in a notice message), or a localized translation of one of these. Always present.

## V

**Severity:** the field contents are `ERROR`, `FATAL`, or `PANIC` (in an error message), or `WARNING`, `NOTICE`, `DEBUG`, `INFO`, or `LOG` (in a notice message). This is identical to the `S` field except that the contents are never localized. This is present only in messages generated by Postgres Pro versions 9.6 and later.

## C

**Code:** the `SQLSTATE` code for the error (see [Appendix A](#)). Not localizable. Always present.

## M

**Message:** the primary human-readable error message. This should be accurate but terse (typically one line). Always present.

D

Detail: an optional secondary error message carrying more detail about the problem. Might run to multiple lines.

H

Hint: an optional suggestion what to do about the problem. This is intended to differ from Detail in that it offers advice (potentially inappropriate) rather than hard facts. Might run to multiple lines.

P

Position: the field value is a decimal ASCII integer, indicating an error cursor position as an index into the original query string. The first character has index 1, and positions are measured in characters not bytes.

p

Internal position: this is defined the same as the P field, but it is used when the cursor position refers to an internally generated command rather than the one submitted by the client. The q field will always appear when this field appears.

q

Internal query: the text of a failed internally-generated command. This could be, for example, a SQL query issued by a PL/pgSQL function.

W

Where: an indication of the context in which the error occurred. Presently this includes a call stack traceback of active procedural language functions and internally-generated queries. The trace is one entry per line, most recent first.

s

Schema name: if the error was associated with a specific database object, the name of the schema containing that object, if any.

t

Table name: if the error was associated with a specific table, the name of the table. (Refer to the schema name field for the name of the table's schema.)

c

Column name: if the error was associated with a specific table column, the name of the column. (Refer to the schema and table name fields to identify the table.)

d

Data type name: if the error was associated with a specific data type, the name of the data type. (Refer to the schema name field for the name of the data type's schema.)

n

Constraint name: if the error was associated with a specific constraint, the name of the constraint. Refer to fields listed above for the associated table or domain. (For this purpose, indexes are treated as constraints, even if they weren't created with constraint syntax.)

F

File: the file name of the source-code location where the error was reported.

L

Line: the line number of the source-code location where the error was reported.

R

Routine: the name of the source-code routine reporting the error.

### Note

The fields for schema name, table name, column name, data type name, and constraint name are supplied only for a limited number of error types; see [Appendix A](#). Frontends should not assume that the presence of any of these fields guarantees the presence of another field. Core error sources observe the interrelationships noted above, but user-defined functions may use these fields in other ways. In the same vein, clients should not assume that these fields denote contemporary objects in the current database.

The client is responsible for formatting displayed information to meet its needs; in particular it should break long lines as needed. Newline characters appearing in the error message fields should be treated as paragraph breaks, not line breaks.

## 50.9. Logical Replication Message Formats

This section describes the detailed format of each logical replication message. These messages are returned either by the replication slot SQL interface or are sent by a walsender. In case of a walsender they are encapsulated inside the replication protocol WAL messages as described in [Section 50.4](#) and generally obey same message flow as physical replication.

Begin

Byte1('B')

Identifies the message as a begin message.

Int64

The final LSN of the transaction.

Int64

Commit timestamp of the transaction. The value is in number of microseconds since Postgres Pro epoch (2000-01-01).

Int32

Xid of the transaction.

Commit

Byte1('C')

Identifies the message as a commit message.

Int8

Flags; currently unused (must be 0).

Int64

The LSN of the commit.

Int64

The end LSN of the transaction.

Int64

Commit timestamp of the transaction. The value is in number of microseconds since Postgres Pro epoch (2000-01-01).

**Origin**

Byte1('O')

Identifies the message as an origin message.

Int64

The LSN of the commit on the origin server.

String

Name of the origin.

Note that there can be multiple Origin messages inside a single transaction.

**Relation**

Byte1('R')

Identifies the message as a relation message.

Int32

ID of the relation.

String

Namespace (empty string for `pg_catalog`).

String

Relation name.

Int8

Replica identity setting for the relation (same as `relreplident` in `pg_class`).

Int16

Number of columns.

Next, the following message part appears for each column (except generated columns):

Int8

Flags for the column. Currently can be either 0 for no flags or 1 which marks the column as part of the key.

String

Name of the column.

Int32

ID of the column's data type.

Int32

Type modifier of the column (`atttypmod`).**Type**

Byte1('Y')

Identifies the message as a type message.

Int32

ID of the data type.

String

Namespace (empty string for `pg_catalog`).

String

Name of the data type.

Insert

Byte1('I')

Identifies the message as an insert message.

Int32

ID of the relation corresponding to the ID in the relation message.

Byte1('N')

Identifies the following TupleData message as a new tuple.

TupleData

TupleData message part representing the contents of new tuple.

Update

Byte1('U')

Identifies the message as an update message.

Int32

ID of the relation corresponding to the ID in the relation message.

Byte1('K')

Identifies the following TupleData submessage as a key. This field is optional and is only present if the update changed data in any of the column(s) that are part of the REPLICATION index.

Byte1('O')

Identifies the following TupleData submessage as an old tuple. This field is optional and is only present if table in which the update happened has REPLICATION set to FULL.

TupleData

TupleData message part representing the contents of the old tuple or primary key. Only present if the previous 'O' or 'K' part is present.

Byte1('N')

Identifies the following TupleData message as a new tuple.

TupleData

TupleData message part representing the contents of a new tuple.

The Update message may contain either a 'K' message part or an 'O' message part or neither of them, but never both of them.

Delete

Byte1('D')

Identifies the message as a delete message.

Int32

ID of the relation corresponding to the ID in the relation message.

Byte1('K')

Identifies the following TupleData submessage as a key. This field is present if the table in which the delete has happened uses an index as REPLICA IDENTITY.

Byte1('O')

Identifies the following TupleData message as an old tuple. This field is present if the table in which the delete happened has REPLICA IDENTITY set to FULL.

TupleData

TupleData message part representing the contents of the old tuple or primary key, depending on the previous field.

The Delete message may contain either a 'K' message part or an 'O' message part, but never both of them.

Truncate

Byte1('T')

Identifies the message as a truncate message.

Int32

Number of relations

Int8

Option bits for TRUNCATE: 1 for CASCADE, 2 for RESTART IDENTITY

Int32

ID of the relation corresponding to the ID in the relation message. This field is repeated for each relation.

The following message parts are shared by the above messages.

TupleData

Int16

Number of columns.

Next, one of the following submessages appears for each column (except generated columns):

Byte1('n')

Identifies the data as NULL value.

Or

Byte1('u')

Identifies unchanged TOASTed value (the actual value is not sent).

Or

Byte1('t')

Identifies the data as text formatted value.

Int32

Length of the column value.

Byte<sub>*n*</sub>

The value of the column, in text format. (A future release might support additional formats.) *n* is the above length.

## 50.10. Summary of Changes since Protocol 2.0

This section provides a quick checklist of changes, for the benefit of developers trying to update existing client libraries to protocol 3.0.

The initial startup packet uses a flexible list-of-strings format instead of a fixed format. Notice that session default values for run-time parameters can now be specified directly in the startup packet. (Actually, you could do that before using the `options` field, but given the limited width of `options` and the lack of any way to quote whitespace in the values, it wasn't a very safe technique.)

All messages now have a length count immediately following the message type byte (except for startup packets, which have no type byte). Also note that `PasswordMessage` now has a type byte.

`ErrorResponse` and `NoticeResponse` ('E' and 'N') messages now contain multiple fields, from which the client code can assemble an error message of the desired level of verbosity. Note that individual fields will typically not end with a newline, whereas the single string sent in the older protocol always did.

The `ReadyForQuery` ('Z') message includes a transaction status indicator.

The distinction between `BinaryRow` and `DataRow` message types is gone; the single `DataRow` message type serves for returning data in all formats. Note that the layout of `DataRow` has changed to make it easier to parse. Also, the representation of binary values has changed: it is no longer directly tied to the server's internal representation.

There is a new “extended query” sub-protocol, which adds the frontend message types `Parse`, `Bind`, `Execute`, `Describe`, `Close`, `Flush`, and `Sync`, and the backend message types `ParseComplete`, `BindComplete`, `PortalSuspended`, `ParameterDescription`, `NoData`, and `CloseComplete`. Existing clients do not have to concern themselves with this sub-protocol, but making use of it might allow improvements in performance or functionality.

`COPY` data is now encapsulated into `CopyData` and `CopyDone` messages. There is a well-defined way to recover from errors during `COPY`. The special “\.” last line is not needed anymore, and is not sent during `COPY OUT`. (It is still recognized as a terminator during `COPY IN`, but its use is deprecated and will eventually be removed.) Binary `COPY` is supported. The `CopyInResponse` and `CopyOutResponse` messages include fields indicating the number of columns and the format of each column.

The layout of `FunctionCall` and `FunctionCallResponse` messages has changed. `FunctionCall` can now support passing `NULL` arguments to functions. It also can handle passing parameters and retrieving results in either text or binary format. There is no longer any reason to consider `FunctionCall` a potential security hole, since it does not offer direct access to internal server data representations.

The backend sends `ParameterStatus` ('S') messages during connection startup for all parameters it considers interesting to the client library. Subsequently, a `ParameterStatus` message is sent whenever the active value changes for any of these parameters.

The `RowDescription` ('T') message carries new table OID and column number fields for each column of the described row. It also shows the format code for each column.

The `CursorResponse` ('P') message is no longer generated by the backend.

The `NotificationResponse` ('A') message has an additional string field, which can carry a “payload” string passed from the `NOTIFY` event sender.

The `EmptyQueryResponse` ('I') message used to include an empty string parameter; this has been removed.

---

# Chapter 51. Writing a Procedural Language Handler

All calls to functions that are written in a language other than the current “version 1” interface for compiled languages (this includes functions in user-defined procedural languages and functions written in SQL) go through a *call handler* function for the specific language. It is the responsibility of the call handler to execute the function in a meaningful way, such as by interpreting the supplied source text. This chapter outlines how a new procedural language's call handler can be written.

The call handler for a procedural language is a “normal” function that must be written in a compiled language such as C, using the version-1 interface, and registered with Postgres Pro as taking no arguments and returning the type `language_handler`. This special pseudo-type identifies the function as a call handler and prevents it from being called directly in SQL commands. For more details on C language calling conventions and dynamic loading, see [Section 35.10](#).

The call handler is called in the same way as any other function: It receives a pointer to a `FunctionCallInfoBaseData` struct containing argument values and information about the called function, and it is expected to return a `Datum` result (and possibly set the `isnull` field of the `FunctionCallInfoBaseData` structure, if it wishes to return an SQL null result). The difference between a call handler and an ordinary callee function is that the `flinfo->fn_oid` field of the `FunctionCallInfoBaseData` structure will contain the OID of the actual function to be called, not of the call handler itself. The call handler must use this field to determine which function to execute. Also, the passed argument list has been set up according to the declaration of the target function, not of the call handler.

It's up to the call handler to fetch the entry of the function from the `pg_proc` system catalog and to analyze the argument and return types of the called function. The `AS` clause from the `CREATE FUNCTION` command for the function will be found in the `prosrc` column of the `pg_proc` row. This is commonly source text in the procedural language, but in theory it could be something else, such as a path name to a file, or anything else that tells the call handler what to do in detail.

Often, the same function is called many times per SQL statement. A call handler can avoid repeated lookups of information about the called function by using the `flinfo->fn_extra` field. This will initially be `NULL`, but can be set by the call handler to point at information about the called function. On subsequent calls, if `flinfo->fn_extra` is already non-`NULL` then it can be used and the information lookup step skipped. The call handler must make sure that `flinfo->fn_extra` is made to point at memory that will live at least until the end of the current query, since an `FmgrInfo` data structure could be kept that long. One way to do this is to allocate the extra data in the memory context specified by `flinfo->fn_mcxt`; such data will normally have the same lifespan as the `FmgrInfo` itself. But the handler could also choose to use a longer-lived memory context so that it can cache function definition information across queries.

When a procedural-language function is invoked as a trigger, no arguments are passed in the usual way, but the `FunctionCallInfoBaseData`'s `context` field points at a `TriggerData` structure, rather than being `NULL` as it is in a plain function call. A language handler should provide mechanisms for procedural-language functions to get at the trigger information.

This is a template for a procedural-language handler written in C:

```
#include "postgres.h"
#include "executor/spi.h"
#include "commands/trigger.h"
#include "fmgr.h"
#include "access/heapam.h"
#include "utils/syscache.h"
#include "catalog/pg_proc.h"
#include "catalog/pg_type.h"
```

```

PG_MODULE_MAGIC;

PG_FUNCTION_INFO_V1(plsample_call_handler);

Datum
plsample_call_handler(PG_FUNCTION_ARGS)
{
    Datum          retval;

    if (CALLED_AS_TRIGGER(fcinfo))
    {
        /*
         * Called as a trigger function
         */
        TriggerData *trigdata = (TriggerData *) fcinfo->context;

        retval = ...
    }
    else
    {
        /*
         * Called as a function
         */

        retval = ...
    }

    return retval;
}

```

Only a few thousand lines of code have to be added instead of the dots to complete the call handler.

After having compiled the handler function into a loadable module (see [Section 35.10.5](#)), the following commands then register the sample procedural language:

```

CREATE FUNCTION plsample_call_handler() RETURNS language_handler
AS 'filename'
LANGUAGE C;
CREATE LANGUAGE plsample
HANDLER plsample_call_handler;

```

Although providing a call handler is sufficient to create a minimal procedural language, there are two other functions that can optionally be provided to make the language more convenient to use. These are a *validator* and an *inline handler*. A validator can be provided to allow language-specific checking to be done during [CREATE FUNCTION](#). An inline handler can be provided to allow the language to support anonymous code blocks executed via the [DO](#) command.

If a validator is provided by a procedural language, it must be declared as a function taking a single parameter of type `oid`. The validator's result is ignored, so it is customarily declared to return `void`. The validator will be called at the end of a `CREATE FUNCTION` command that has created or updated a function written in the procedural language. The passed-in OID is the OID of the function's `pg_proc` row. The validator must fetch this row in the usual way, and do whatever checking is appropriate. First, call `CheckFunctionValidatorAccess()` to diagnose explicit calls to the validator that the user could not achieve through `CREATE FUNCTION`. Typical checks then include verifying that the function's argument and result types are supported by the language, and that the function's body is syntactically correct in the language. If the validator finds the function to be okay, it should just return. If it finds an error, it should report that via the normal `ereport()` error reporting mechanism. Throwing an error will force a transaction rollback and thus prevent the incorrect function definition from being committed.

Validator functions should typically honor the `check_function_bodies` parameter: if it is turned off then any expensive or context-sensitive checking should be skipped. If the language provides for code execution at compilation time, the validator must suppress checks that would induce such execution. In particular, this parameter is turned off by `pg_dump` so that it can load procedural language functions without worrying about side effects or dependencies of the function bodies on other database objects. (Because of this requirement, the call handler should avoid assuming that the validator has fully checked the function. The point of having a validator is not to let the call handler omit checks, but to notify the user immediately if there are obvious errors in a `CREATE FUNCTION` command.) While the choice of exactly what to check is mostly left to the discretion of the validator function, note that the core `CREATE FUNCTION` code only executes `SET` clauses attached to a function when `check_function_bodies` is on. Therefore, checks whose results might be affected by GUC parameters definitely should be skipped when `check_function_bodies` is off, to avoid false failures when reloading a dump.

If an inline handler is provided by a procedural language, it must be declared as a function taking a single parameter of type `internal`. The inline handler's result is ignored, so it is customarily declared to return `void`. The inline handler will be called when a `DO` statement is executed specifying the procedural language. The parameter actually passed is a pointer to an `InlineCodeBlock` struct, which contains information about the `DO` statement's parameters, in particular the text of the anonymous code block to be executed. The inline handler should execute this code and return.

It's recommended that you wrap all these function declarations, as well as the `CREATE LANGUAGE` command itself, into an *extension* so that a simple `CREATE EXTENSION` command is sufficient to install the language. See [Section 35.17](#) for information about writing extensions.

The procedural languages included in the standard distribution are good references when trying to write your own language handler. The [CREATE LANGUAGE](#) reference page has some useful details.

---

# Chapter 52. Writing a Foreign Data Wrapper

All operations on a foreign table are handled through its foreign data wrapper, which consists of a set of functions that the core server calls. The foreign data wrapper is responsible for fetching data from the remote data source and returning it to the Postgres Pro executor. If updating foreign tables is to be supported, the wrapper must handle that, too. This chapter outlines how to write a new foreign data wrapper.

The foreign data wrappers included in the standard distribution are good references when trying to write your own. Look into the `contrib` subdirectory of the source tree. The [CREATE FOREIGN DATA WRAPPER](#) reference page also has some useful details.

## Note

The SQL standard specifies an interface for writing foreign data wrappers. However, Postgres Pro does not implement that API, because the effort to accommodate it into Postgres Pro would be large, and the standard API hasn't gained wide adoption anyway.

## 52.1. Foreign Data Wrapper Functions

The FDW author needs to implement a handler function, and optionally a validator function. Both functions must be written in a compiled language such as C, using the version-1 interface. For details on C language calling conventions and dynamic loading, see [Section 35.10](#).

The handler function simply returns a struct of function pointers to callback functions that will be called by the planner, executor, and various maintenance commands. Most of the effort in writing an FDW is in implementing these callback functions. The handler function must be registered with Postgres Pro as taking no arguments and returning the special pseudo-type `fdw_handler`. The callback functions are plain C functions and are not visible or callable at the SQL level. The callback functions are described in [Section 52.2](#).

The validator function is responsible for validating options given in `CREATE` and `ALTER` commands for its foreign data wrapper, as well as foreign servers, user mappings, and foreign tables using the wrapper. The validator function must be registered as taking two arguments, a text array containing the options to be validated, and an OID representing the type of object the options are associated with (in the form of the OID of the system catalog the object would be stored in, either `ForeignDataWrapperRelationId`, `ForeignServerRelationId`, `UserMappingRelationId`, or `ForeignTableRelationId`). If no validator function is supplied, options are not checked at object creation time or object alteration time.

## 52.2. Foreign Data Wrapper Callback Routines

The FDW handler function returns a palloc'd `FdwRoutine` struct containing pointers to the callback functions described below. The scan-related functions are required, the rest are optional.

The `FdwRoutine` struct type is declared in `src/include/foreign/fdwapi.h`, which see for additional details.

### 52.2.1. FDW Routines for Scanning Foreign Tables

```
void
GetForeignRelSize(PlannerInfo *root,
                 RelOptInfo *baserel,
                 Oid foreigntableid);
```

Obtain relation size estimates for a foreign table. This is called at the beginning of planning for a query that scans a foreign table. `root` is the planner's global information about the query; `baserel` is the planner's information about this table; and `foreigntableid` is the `pg_class` OID of the foreign table.

(`foreigntableid` could be obtained from the planner data structures, but it's passed explicitly to save effort.)

This function should update `baserel->rows` to be the expected number of rows returned by the table scan, after accounting for the filtering done by the restriction quals. The initial value of `baserel->rows` is just a constant default estimate, which should be replaced if at all possible. The function may also choose to update `baserel->width` if it can compute a better estimate of the average result row width. (The initial value is based on column data types and on column average-width values measured by the last `ANALYZE`.) Also, this function may update `baserel->tuples` if it can compute a better estimate of the foreign table's total row count. (The initial value is from `pg_class.reltuples` which represents the total row count seen by the last `ANALYZE`.)

See [Section 52.4](#) for additional information.

```
void
GetForeignPaths(PlannerInfo *root,
                RelOptInfo *baserel,
                Oid foreigntableid);
```

Create possible access paths for a scan on a foreign table. This is called during query planning. The parameters are the same as for `GetForeignRelSize`, which has already been called.

This function must generate at least one access path (`ForeignPath` node) for a scan on the foreign table and must call `add_path` to add each such path to `baserel->pathlist`. It's recommended to use `create_foreignscan_path` to build the `ForeignPath` nodes. The function can generate multiple access paths, e.g., a path which has valid `pathkeys` to represent a pre-sorted result. Each access path must contain cost estimates, and can contain any FDW-private information that is needed to identify the specific scan method intended.

See [Section 52.4](#) for additional information.

```
ForeignScan *
GetForeignPlan(PlannerInfo *root,
               RelOptInfo *baserel,
               Oid foreigntableid,
               ForeignPath *best_path,
               List *tlist,
               List *scan_clauses,
               Plan *outer_plan);
```

Create a `ForeignScan` plan node from the selected foreign access path. This is called at the end of query planning. The parameters are as for `GetForeignRelSize`, plus the selected `ForeignPath` (previously produced by `GetForeignPaths`, `GetForeignJoinPaths`, or `GetForeignUpperPaths`), the target list to be emitted by the plan node, the restriction clauses to be enforced by the plan node, and the outer subplan of the `ForeignScan`, which is used for rechecks performed by `RecheckForeignScan`. (If the path is for a join rather than a base relation, `foreigntableid` is `InvalidOid`.)

This function must create and return a `ForeignScan` plan node; it's recommended to use `make_foreignscan` to build the `ForeignScan` node.

See [Section 52.4](#) for additional information.

```
void
BeginForeignScan(ForeignScanState *node,
                 int eflags);
```

Begin executing a foreign scan. This is called during executor startup. It should perform any initialization needed before the scan can start, but not start executing the actual scan (that should be done upon the first call to `IterateForeignScan`). The `ForeignScanState` node has already been created, but its `fdw_state` field is still `NULL`. Information about the table to scan is accessible through the `ForeignScanState` node (in particular, from the underlying `ForeignScan` plan node, which contains

any FDW-private information provided by `GetForeignPlan`). `eflags` contains flag bits describing the executor's operating mode for this plan node.

Note that when `(eflags & EXEC_FLAG_EXPLAIN_ONLY)` is true, this function should not perform any externally-visible actions; it should only do the minimum required to make the node state valid for `ExplainForeignScan` and `EndForeignScan`.

```
TupleTableSlot *
IterateForeignScan(ForeignScanState *node);
```

Fetch one row from the foreign source, returning it in a tuple table slot (the node's `ScanTupleSlot` should be used for this purpose). Return NULL if no more rows are available. The tuple table slot infrastructure allows either a physical or virtual tuple to be returned; in most cases the latter choice is preferable from a performance standpoint. Note that this is called in a short-lived memory context that will be reset between invocations. Create a memory context in `BeginForeignScan` if you need longer-lived storage, or use the `es_query_cxt` of the node's `EState`.

The rows returned must match the `fdw_scan_tlist` target list if one was supplied, otherwise they must match the row type of the foreign table being scanned. If you choose to optimize away fetching columns that are not needed, you should insert nulls in those column positions, or else generate a `fdw_scan_tlist` list with those columns omitted.

Note that Postgres Pro's executor doesn't care whether the rows returned violate any constraints that were defined on the foreign table — but the planner does care, and may optimize queries incorrectly if there are rows visible in the foreign table that do not satisfy a declared constraint. If a constraint is violated when the user has declared that the constraint should hold true, it may be appropriate to raise an error (just as you would need to do in the case of a data type mismatch).

```
void
ReScanForeignScan(ForeignScanState *node);
```

Restart the scan from the beginning. Note that any parameters the scan depends on may have changed value, so the new scan does not necessarily return exactly the same rows.

```
void
EndForeignScan(ForeignScanState *node);
```

End the scan and release resources. It is normally not important to release palloc'd memory, but for example open files and connections to remote servers should be cleaned up.

## 52.2.2. FDW Routines for Scanning Foreign Joins

If an FDW supports performing foreign joins remotely (rather than by fetching both tables' data and doing the join locally), it should provide this callback function:

```
void
GetForeignJoinPaths(PlannerInfo *root,
                   RelOptInfo *joinrel,
                   RelOptInfo *outerrel,
                   RelOptInfo *innerrel,
                   JoinType jointype,
                   JoinPathExtraData *extra);
```

Create possible access paths for a join of two (or more) foreign tables that all belong to the same foreign server. This optional function is called during query planning. As with `GetForeignPaths`, this function should generate `ForeignPath` path(s) for the supplied `joinrel` (use `create_foreign_join_path` to build them), and call `add_path` to add these paths to the set of paths considered for the join. But unlike `GetForeignPaths`, it is not necessary that this function succeed in creating at least one path, since paths involving local joining are always possible.

Note that this function will be invoked repeatedly for the same join relation, with different combinations of inner and outer relations; it is the responsibility of the FDW to minimize duplicated work.

If a `ForeignPath` path is chosen for the join, it will represent the entire join process; paths generated for the component tables and subsidiary joins will not be used. Subsequent processing of the join path proceeds much as it does for a path scanning a single foreign table. One difference is that the `scanrelid` of the resulting `ForeignScan` plan node should be set to zero, since there is no single relation that it represents; instead, the `fs_relids` field of the `ForeignScan` node represents the set of relations that were joined. (The latter field is set up automatically by the core planner code, and need not be filled by the FDW.) Another difference is that, because the column list for a remote join cannot be found from the system catalogs, the FDW must fill `fdw_scan_tlist` with an appropriate list of `TargetEntry` nodes, representing the set of columns it will supply at run time in the tuples it returns.

See [Section 52.4](#) for additional information.

### 52.2.3. FDW Routines for Planning Post-Scan/Join Processing

If an FDW supports performing remote post-scan/join processing, such as remote aggregation, it should provide this callback function:

```
void
GetForeignUpperPaths(PlannerInfo *root,
                    UpperRelationKind stage,
                    RelOptInfo *input_rel,
                    RelOptInfo *output_rel,
                    void *extra);
```

Create possible access paths for *upper relation* processing, which is the planner's term for all post-scan/join query processing, such as aggregation, window functions, sorting, and table updates. This optional function is called during query planning. Currently, it is called only if all base relation(s) involved in the query belong to the same FDW. This function should generate `ForeignPath` path(s) for any post-scan/join processing that the FDW knows how to perform remotely (use `create_foreign_upper_path` to build them), and call `add_path` to add these paths to the indicated upper relation. As with `GetForeignJoinPaths`, it is not necessary that this function succeed in creating any paths, since paths involving local processing are always possible.

The `stage` parameter identifies which post-scan/join step is currently being considered. `output_rel` is the upper relation that should receive paths representing computation of this step, and `input_rel` is the relation representing the input to this step. The `extra` parameter provides additional details, currently, it is set only for `UPPERREL_PARTIAL_GROUP_AGG` or `UPPERREL_GROUP_AGG`, in which case it points to a `GroupPathExtraData` structure; or for `UPPERREL_FINAL`, in which case it points to a `FinalPathExtraData` structure. (Note that `ForeignPath` paths added to `output_rel` would typically not have any direct dependency on paths of the `input_rel`, since their processing is expected to be done externally. However, examining paths previously generated for the previous processing step can be useful to avoid redundant planning work.)

See [Section 52.4](#) for additional information.

### 52.2.4. FDW Routines for Updating Foreign Tables

If an FDW supports writable foreign tables, it should provide some or all of the following callback functions depending on the needs and capabilities of the FDW:

```
void
AddForeignUpdateTargets(Query *parsetree,
                      RangeTblEntry *target_rte,
                      Relation target_relation);
```

`UPDATE` and `DELETE` operations are performed against rows previously fetched by the table-scanning functions. The FDW may need extra information, such as a row ID or the values of primary-key columns, to ensure that it can identify the exact row to update or delete. To support that, this function can add extra hidden, or “junk”, target columns to the list of columns that are to be retrieved from the foreign table during an `UPDATE` or `DELETE`.

To do that, add `TargetEntry` items to `parsetree->targetList`, containing expressions for the extra values to be fetched. Each such entry must be marked `resjunk = true`, and must have a distinct `resname` that will identify it at execution time. Avoid using names matching `ctidN`, `wholerow`, or `wholerowN`, as the core system can generate junk columns of these names. If the extra expressions are more complex than simple Vars, they must be run through `eval_const_expressions` before adding them to the target list.

Although this function is called during planning, the information provided is a bit different from that available to other planning routines. `parsetree` is the parse tree for the `UPDATE` or `DELETE` command, while `target_rte` and `target_relation` describe the target foreign table.

If the `AddForeignUpdateTargets` pointer is set to `NULL`, no extra target expressions are added. (This will make it impossible to implement `DELETE` operations, though `UPDATE` may still be feasible if the FDW relies on an unchanging primary key to identify rows.)

```
List *
PlanForeignModify(PlannerInfo *root,
                  ModifyTable *plan,
                  Index resultRelation,
                  int subplan_index);
```

Perform any additional planning actions needed for an insert, update, or delete on a foreign table. This function generates the FDW-private information that will be attached to the `ModifyTable` plan node that performs the update action. This private information must have the form of a `List`, and will be delivered to `BeginForeignModify` during the execution stage.

`root` is the planner's global information about the query. `plan` is the `ModifyTable` plan node, which is complete except for the `fdwPrivLists` field. `resultRelation` identifies the target foreign table by its range table index. `subplan_index` identifies which target of the `ModifyTable` plan node this is, counting from zero; use this if you want to index into `plan->plans` or other substructure of the plan node.

See [Section 52.4](#) for additional information.

If the `PlanForeignModify` pointer is set to `NULL`, no additional plan-time actions are taken, and the `fdw_private` list delivered to `BeginForeignModify` will be `NIL`.

```
void
BeginForeignModify(ModifyTableState *mtstate,
                  ResultRelInfo *rinfo,
                  List *fdw_private,
                  int subplan_index,
                  int eflags);
```

Begin executing a foreign table modification operation. This routine is called during executor startup. It should perform any initialization needed prior to the actual table modifications. Subsequently, `ExecForeignInsert`, `ExecForeignUpdate` or `ExecForeignDelete` will be called for each tuple to be inserted, updated, or deleted.

`mtstate` is the overall state of the `ModifyTable` plan node being executed; global data about the plan and execution state is available via this structure. `rinfo` is the `ResultRelInfo` struct describing the target foreign table. (The `ri_FdwState` field of `ResultRelInfo` is available for the FDW to store any private state it needs for this operation.) `fdw_private` contains the private data generated by `PlanForeignModify`, if any. `subplan_index` identifies which target of the `ModifyTable` plan node this is. `eflags` contains flag bits describing the executor's operating mode for this plan node.

Note that when `(eflags & EXEC_FLAG_EXPLAIN_ONLY)` is true, this function should not perform any externally-visible actions; it should only do the minimum required to make the node state valid for `ExplainForeignModify` and `EndForeignModify`.

If the `BeginForeignModify` pointer is set to `NULL`, no action is taken during executor startup.

```
TupleTableSlot *
ExecForeignInsert (EState *estate,
                  ResultRelInfo *rinfo,
                  TupleTableSlot *slot,
                  TupleTableSlot *planSlot);
```

Insert one tuple into the foreign table. `estate` is global execution state for the query. `rinfo` is the `ResultRelInfo` struct describing the target foreign table. `slot` contains the tuple to be inserted; it will match the row-type definition of the foreign table. `planSlot` contains the tuple that was generated by the `ModifyTable` plan node's subplan; it differs from `slot` in possibly containing additional “junk” columns. (The `planSlot` is typically of little interest for `INSERT` cases, but is provided for completeness.)

The return value is either a slot containing the data that was actually inserted (this might differ from the data supplied, for example as a result of trigger actions), or `NULL` if no row was actually inserted (again, typically as a result of triggers). The passed-in `slot` can be re-used for this purpose.

The data in the returned slot is used only if the `INSERT` statement has a `RETURNING` clause or involves a view `WITH CHECK OPTION`; or if the foreign table has an `AFTER ROW` trigger. Triggers require all columns, but the FDW could choose to optimize away returning some or all columns depending on the contents of the `RETURNING` clause or `WITH CHECK OPTION` constraints. Regardless, some slot must be returned to indicate success, or the query's reported row count will be wrong.

If the `ExecForeignInsert` pointer is set to `NULL`, attempts to insert into the foreign table will fail with an error message.

Note that this function is also called when inserting routed tuples into a foreign-table partition or executing `COPY FROM` on a foreign table, in which case it is called in a different way than it is in the `INSERT` case. See the callback functions described below that allow the FDW to support that.

```
TupleTableSlot *
ExecForeignUpdate (EState *estate,
                  ResultRelInfo *rinfo,
                  TupleTableSlot *slot,
                  TupleTableSlot *planSlot);
```

Update one tuple in the foreign table. `estate` is global execution state for the query. `rinfo` is the `ResultRelInfo` struct describing the target foreign table. `slot` contains the new data for the tuple; it will match the row-type definition of the foreign table. `planSlot` contains the tuple that was generated by the `ModifyTable` plan node's subplan; it differs from `slot` in possibly containing additional “junk” columns. In particular, any junk columns that were requested by `AddForeignUpdateTargets` will be available from this slot.

The return value is either a slot containing the row as it was actually updated (this might differ from the data supplied, for example as a result of trigger actions), or `NULL` if no row was actually updated (again, typically as a result of triggers). The passed-in `slot` can be re-used for this purpose.

The data in the returned slot is used only if the `UPDATE` statement has a `RETURNING` clause or involves a view `WITH CHECK OPTION`; or if the foreign table has an `AFTER ROW` trigger. Triggers require all columns, but the FDW could choose to optimize away returning some or all columns depending on the contents of the `RETURNING` clause or `WITH CHECK OPTION` constraints. Regardless, some slot must be returned to indicate success, or the query's reported row count will be wrong.

If the `ExecForeignUpdate` pointer is set to `NULL`, attempts to update the foreign table will fail with an error message.

```
TupleTableSlot *
ExecForeignDelete (EState *estate,
                  ResultRelInfo *rinfo,
                  TupleTableSlot *slot,
                  TupleTableSlot *planSlot);
```

Delete one tuple from the foreign table. `estate` is global execution state for the query. `rinfo` is the `ResultRelInfo` struct describing the target foreign table. `slot` contains nothing useful upon call, but can be used to hold the returned tuple. `planSlot` contains the tuple that was generated by the `ModifyTable` plan node's subplan; in particular, it will carry any junk columns that were requested by `AddForeignUpdateTargets`. The junk column(s) must be used to identify the tuple to be deleted.

The return value is either a slot containing the row that was deleted, or `NULL` if no row was deleted (typically as a result of triggers). The passed-in `slot` can be used to hold the tuple to be returned.

The data in the returned slot is used only if the `DELETE` query has a `RETURNING` clause or the foreign table has an `AFTER ROW` trigger. Triggers require all columns, but the FDW could choose to optimize away returning some or all columns depending on the contents of the `RETURNING` clause. Regardless, some slot must be returned to indicate success, or the query's reported row count will be wrong.

If the `ExecForeignDelete` pointer is set to `NULL`, attempts to delete from the foreign table will fail with an error message.

```
void
EndForeignModify (EState *estate,
                 ResultRelInfo *rinfo);
```

End the table update and release resources. It is normally not important to release `palloc'd` memory, but for example open files and connections to remote servers should be cleaned up.

If the `EndForeignModify` pointer is set to `NULL`, no action is taken during executor shutdown.

Tuples inserted into a partitioned table by `INSERT` or `COPY FROM` are routed to partitions. If an FDW supports routable foreign-table partitions, it should also provide the following callback functions. These functions are also called when `COPY FROM` is executed on a foreign table.

```
void
BeginForeignInsert (ModifyTableState *mtstate,
                  ResultRelInfo *rinfo);
```

Begin executing an insert operation on a foreign table. This routine is called right before the first tuple is inserted into the foreign table in both cases when it is the partition chosen for tuple routing and the target specified in a `COPY FROM` command. It should perform any initialization needed prior to the actual insertion. Subsequently, `ExecForeignInsert` will be called for each tuple to be inserted into the foreign table.

`mtstate` is the overall state of the `ModifyTable` plan node being executed; global data about the plan and execution state is available via this structure. `rinfo` is the `ResultRelInfo` struct describing the target foreign table. (The `ri_FdwState` field of `ResultRelInfo` is available for the FDW to store any private state it needs for this operation.)

When this is called by a `COPY FROM` command, the plan-related global data in `mtstate` is not provided and the `planSlot` parameter of `ExecForeignInsert` subsequently called for each inserted tuple is `NULL`, whether the foreign table is the partition chosen for tuple routing or the target specified in the command.

If the `BeginForeignInsert` pointer is set to `NULL`, no action is taken for the initialization.

Note that if the FDW does not support routable foreign-table partitions and/or executing `COPY FROM` on foreign tables, this function or `ExecForeignInsert` subsequently called must throw error as needed.

```
void
EndForeignInsert (EState *estate,
                 ResultRelInfo *rinfo);
```

End the insert operation and release resources. It is normally not important to release `palloc'd` memory, but for example open files and connections to remote servers should be cleaned up.

If the `EndForeignInsert` pointer is set to `NULL`, no action is taken for the termination.

```
int
IsForeignRelUpdatable(Relation rel);
```

Report which update operations the specified foreign table supports. The return value should be a bit mask of rule event numbers indicating which operations are supported by the foreign table, using the `CmdType` enumeration; that is,  $(1 \ll \text{CMD\_UPDATE}) = 4$  for `UPDATE`,  $(1 \ll \text{CMD\_INSERT}) = 8$  for `INSERT`, and  $(1 \ll \text{CMD\_DELETE}) = 16$  for `DELETE`.

If the `IsForeignRelUpdatable` pointer is set to `NULL`, foreign tables are assumed to be insertable, updatable, or deletable if the FDW provides `ExecForeignInsert`, `ExecForeignUpdate`, or `ExecForeignDelete` respectively. This function is only needed if the FDW supports some tables that are updatable and some that are not. (Even then, it's permissible to throw an error in the execution routine instead of checking in this function. However, this function is used to determine updatability for display in the `information_schema` views.)

Some inserts, updates, and deletes to foreign tables can be optimized by implementing an alternative set of interfaces. The ordinary interfaces for inserts, updates, and deletes fetch rows from the remote server and then modify those rows one at a time. In some cases, this row-by-row approach is necessary, but it can be inefficient. If it is possible for the foreign server to determine which rows should be modified without actually retrieving them, and if there are no local structures which would affect the operation (row-level local triggers, stored generated columns, or `WITH CHECK OPTION` constraints from parent views), then it is possible to arrange things so that the entire operation is performed on the remote server. The interfaces described below make this possible.

```
bool
PlanDirectModify(PlannerInfo *root,
                 ModifyTable *plan,
                 Index resultRelation,
                 int subplan_index);
```

Decide whether it is safe to execute a direct modification on the remote server. If so, return `true` after performing planning actions needed for that. Otherwise, return `false`. This optional function is called during query planning. If this function succeeds, `BeginDirectModify`, `IterateDirectModify` and `EndDirectModify` will be called at the execution stage, instead. Otherwise, the table modification will be executed using the table-updating functions described above. The parameters are the same as for `PlanForeignModify`.

To execute the direct modification on the remote server, this function must rewrite the target subplan with a `ForeignScan` plan node that executes the direct modification on the remote server. The operation field of the `ForeignScan` must be set to the `CmdType` enumeration appropriately; that is, `CMD_UPDATE` for `UPDATE`, `CMD_INSERT` for `INSERT`, and `CMD_DELETE` for `DELETE`.

See [Section 52.4](#) for additional information.

If the `PlanDirectModify` pointer is set to `NULL`, no attempts to execute a direct modification on the remote server are taken.

```
void
BeginDirectModify(ForeignScanState *node,
                 int eflags);
```

Prepare to execute a direct modification on the remote server. This is called during executor startup. It should perform any initialization needed prior to the direct modification (that should be done upon the first call to `IterateDirectModify`). The `ForeignScanState` node has already been created, but its `fdw_state` field is still `NULL`. Information about the table to modify is accessible through the `ForeignScanState` node (in particular, from the underlying `ForeignScan` plan node, which contains any FDW-private information provided by `PlanDirectModify`). `eflags` contains flag bits describing the executor's operating mode for this plan node.

Note that when (`eflags & EXEC_FLAG_EXPLAIN_ONLY`) is true, this function should not perform any externally-visible actions; it should only do the minimum required to make the node state valid for `ExplainDirectModify` and `EndDirectModify`.

If the `BeginDirectModify` pointer is set to `NULL`, no attempts to execute a direct modification on the remote server are taken.

```
TupleTableSlot *
IterateDirectModify(ForeignScanState *node);
```

When the `INSERT`, `UPDATE` or `DELETE` query doesn't have a `RETURNING` clause, just return `NULL` after a direct modification on the remote server. When the query has the clause, fetch one result containing the data needed for the `RETURNING` calculation, returning it in a tuple table slot (the node's `ScanTupleSlot` should be used for this purpose). The data that was actually inserted, updated or deleted must be stored in the `es_result_relation_info->ri_projectReturning->pi_exprContext->ecxt_scantuple` of the node's `EState`. Return `NULL` if no more rows are available. Note that this is called in a short-lived memory context that will be reset between invocations. Create a memory context in `BeginDirectModify` if you need longer-lived storage, or use the `es_query_cxt` of the node's `EState`.

The rows returned must match the `fdw_scan_tlist` target list if one was supplied, otherwise they must match the row type of the foreign table being updated. If you choose to optimize away fetching columns that are not needed for the `RETURNING` calculation, you should insert nulls in those column positions, or else generate a `fdw_scan_tlist` list with those columns omitted.

Whether the query has the clause or not, the query's reported row count must be incremented by the FDW itself. When the query doesn't have the clause, the FDW must also increment the row count for the `ForeignScanState` node in the `EXPLAIN ANALYZE` case.

If the `IterateDirectModify` pointer is set to `NULL`, no attempts to execute a direct modification on the remote server are taken.

```
void
EndDirectModify(ForeignScanState *node);
```

Clean up following a direct modification on the remote server. It is normally not important to release `palloc'd` memory, but for example open files and connections to the remote server should be cleaned up.

If the `EndDirectModify` pointer is set to `NULL`, no attempts to execute a direct modification on the remote server are taken.

## 52.2.5. FDW Routines for Row Locking

If an FDW wishes to support *late row locking* (as described in [Section 52.5](#)), it must provide the following callback functions:

```
RowMarkType
GetForeignRowMarkType(RangeTblEntry *rte,
                      LockClauseStrength strength);
```

Report which row-marking option to use for a foreign table. `rte` is the `RangeTblEntry` node for the table and `strength` describes the lock strength requested by the relevant `FOR UPDATE/SHARE` clause, if any. The result must be a member of the `RowMarkType` enum type.

This function is called during query planning for each foreign table that appears in an `UPDATE`, `DELETE`, or `SELECT FOR UPDATE/SHARE` query and is not the target of `UPDATE` or `DELETE`.

If the `GetForeignRowMarkType` pointer is set to `NULL`, the `ROW_MARK_COPY` option is always used. (This implies that `RefetchForeignRow` will never be called, so it need not be provided either.)

See [Section 52.5](#) for more information.

```
void
RefetchForeignRow(EState *estate,
                  ExecRowMark *erm,
                  Datum rowid,
                  TupleTableSlot *slot,
                  bool *updated);
```

Re-fetch one tuple slot from the foreign table, after locking it if required. `estate` is global execution state for the query. `erm` is the `ExecRowMark` struct describing the target foreign table and the row lock type (if any) to acquire. `rowid` identifies the tuple to be fetched. `slot` contains nothing useful upon call, but can be used to hold the returned tuple. `updated` is an output parameter.

This function should store the tuple into the provided slot, or clear it if the row lock couldn't be obtained. The row lock type to acquire is defined by `erm->markType`, which is the value previously returned by `GetForeignRowMarkType`. (`ROW_MARK_REFERENCE` means to just re-fetch the tuple without acquiring any lock, and `ROW_MARK_COPY` will never be seen by this routine.)

In addition, `*updated` should be set to `true` if what was fetched was an updated version of the tuple rather than the same version previously obtained. (If the FDW cannot be sure about this, always returning `true` is recommended.)

Note that by default, failure to acquire a row lock should result in raising an error; returning with an empty slot is only appropriate if the `SKIP LOCKED` option is specified by `erm->waitPolicy`.

The `rowid` is the `ctid` value previously read for the row to be re-fetched. Although the `rowid` value is passed as a `Datum`, it can currently only be a `tid`. The function API is chosen in hopes that it may be possible to allow other data types for row IDs in future.

If the `RefetchForeignRow` pointer is set to `NULL`, attempts to re-fetch rows will fail with an error message.

See [Section 52.5](#) for more information.

```
bool
RecheckForeignScan(ForeignScanState *node,
                   TupleTableSlot *slot);
```

Recheck that a previously-returned tuple still matches the relevant scan and join qualifiers, and possibly provide a modified version of the tuple. For foreign data wrappers which do not perform join pushdown, it will typically be more convenient to set this to `NULL` and instead set `fdw_recheck_qual` appropriately. When outer joins are pushed down, however, it isn't sufficient to reapply the checks relevant to all the base tables to the result tuple, even if all needed attributes are present, because failure to match some qualifier might result in some attributes going to `NULL`, rather than in no tuple being returned. `RecheckForeignScan` can recheck qualifiers and return `true` if they are still satisfied and `false` otherwise, but it can also store a replacement tuple into the supplied slot.

To implement join pushdown, a foreign data wrapper will typically construct an alternative local join plan which is used only for rechecks; this will become the outer subplan of the `ForeignScan`. When a recheck is required, this subplan can be executed and the resulting tuple can be stored in the slot. This plan need not be efficient since no base table will return more than one row; for example, it may implement all joins as nested loops. The function `GetExistingLocalJoinPath` may be used to search existing paths for a suitable local join path, which can be used as the alternative local join plan. `GetExistingLocalJoinPath` searches for an unparameterized path in the path list of the specified join relation. (If it does not find such a path, it returns `NULL`, in which case a foreign data wrapper may build the local path by itself or may choose not to create access paths for that join.)

## 52.2.6. FDW Routines for EXPLAIN

```
void
ExplainForeignScan(ForeignScanState *node,
                   ExplainState *es);
```

Print additional `EXPLAIN` output for a foreign table scan. This function can call `ExplainPropertyText` and related functions to add fields to the `EXPLAIN` output. The flag fields in `es` can be used to determine what to print, and the state of the `ForeignScanState` node can be inspected to provide run-time statistics in the `EXPLAIN ANALYZE` case.

If the `ExplainForeignScan` pointer is set to `NULL`, no additional information is printed during `EXPLAIN`.

```
void
ExplainForeignModify(ModifyTableState *mtstate,
                    ResultRelInfo *rinfo,
                    List *fdw_private,
                    int subplan_index,
                    struct ExplainState *es);
```

Print additional `EXPLAIN` output for a foreign table update. This function can call `ExplainPropertyText` and related functions to add fields to the `EXPLAIN` output. The flag fields in `es` can be used to determine what to print, and the state of the `ModifyTableState` node can be inspected to provide run-time statistics in the `EXPLAIN ANALYZE` case. The first four arguments are the same as for `BeginForeignModify`.

If the `ExplainForeignModify` pointer is set to `NULL`, no additional information is printed during `EXPLAIN`.

```
void
ExplainDirectModify(ForeignScanState *node,
                   ExplainState *es);
```

Print additional `EXPLAIN` output for a direct modification on the remote server. This function can call `ExplainPropertyText` and related functions to add fields to the `EXPLAIN` output. The flag fields in `es` can be used to determine what to print, and the state of the `ForeignScanState` node can be inspected to provide run-time statistics in the `EXPLAIN ANALYZE` case.

If the `ExplainDirectModify` pointer is set to `NULL`, no additional information is printed during `EXPLAIN`.

### 52.2.7. FDW Routines for ANALYZE

```
bool
AnalyzeForeignTable(Relation relation,
                   AcquireSampleRowsFunc *func,
                   BlockNumber *totalpages);
```

This function is called when `ANALYZE` is executed on a foreign table. If the FDW can collect statistics for this foreign table, it should return `true`, and provide a pointer to a function that will collect sample rows from the table in `func`, plus the estimated size of the table in pages in `totalpages`. Otherwise, return `false`.

If the FDW does not support collecting statistics for any tables, the `AnalyzeForeignTable` pointer can be set to `NULL`.

If provided, the sample collection function must have the signature

```
int
AcquireSampleRowsFunc(Relation relation,
                     int elevel,
                     HeapTuple *rows,
                     int targrows,
                     double *totalrows,
                     double *totaldeadrows);
```

A random sample of up to `targrows` rows should be collected from the table and stored into the caller-provided `rows` array. The actual number of rows collected must be returned. In addition, store estimates of the total numbers of live and dead rows in the table into the output parameters `totalrows` and `totaldeadrows`. (Set `totaldeadrows` to zero if the FDW does not have any concept of dead rows.)

## 52.2.8. FDW Routines for IMPORT FOREIGN SCHEMA

```
List *
ImportForeignSchema(ImportForeignSchemaStmt *stmt, Oid serverOid);
```

Obtain a list of foreign table creation commands. This function is called when executing **IMPORT FOREIGN SCHEMA**, and is passed the parse tree for that statement, as well as the OID of the foreign server to use. It should return a list of C strings, each of which must contain a **CREATE FOREIGN TABLE** command. These strings will be parsed and executed by the core server.

Within the `ImportForeignSchemaStmt` struct, `remote_schema` is the name of the remote schema from which tables are to be imported. `list_type` identifies how to filter table names: `FDW_IMPORT_SCHEMA_ALL` means that all tables in the remote schema should be imported (in this case `table_list` is empty), `FDW_IMPORT_SCHEMA_LIMIT_TO` means to include only tables listed in `table_list`, and `FDW_IMPORT_SCHEMA_EXCEPT` means to exclude the tables listed in `table_list`. `options` is a list of options used for the import process. The meanings of the options are up to the FDW. For example, an FDW could use an option to define whether the `NOT NULL` attributes of columns should be imported. These options need not have anything to do with those supported by the FDW as database object options.

The FDW may ignore the `local_schema` field of the `ImportForeignSchemaStmt`, because the core server will automatically insert that name into the parsed `CREATE FOREIGN TABLE` commands.

The FDW does not have to concern itself with implementing the filtering specified by `list_type` and `table_list`, either, as the core server will automatically skip any returned commands for tables excluded according to those options. However, it's often useful to avoid the work of creating commands for excluded tables in the first place. The function `IsImportableForeignTable()` may be useful to test whether a given foreign-table name will pass the filter.

If the FDW does not support importing table definitions, the `ImportForeignSchema` pointer can be set to `NULL`.

## 52.2.9. FDW Routines for Parallel Execution

A `ForeignScan` node can, optionally, support parallel execution. A parallel `ForeignScan` will be executed in multiple processes and must return each row exactly once across all cooperating processes. To do this, processes can coordinate through fixed-size chunks of dynamic shared memory. This shared memory is not guaranteed to be mapped at the same address in every process, so it must not contain pointers. The following functions are all optional, but most are required if parallel execution is to be supported.

```
bool
IsForeignScanParallelSafe(PlannerInfo *root, RelOptInfo *rel,
                          RangeTblEntry *rte);
```

Test whether a scan can be performed within a parallel worker. This function will only be called when the planner believes that a parallel plan might be possible, and should return `true` if it is safe for that scan to run within a parallel worker. This will generally not be the case if the remote data source has transaction semantics, unless the worker's connection to the data can somehow be made to share the same transaction context as the leader.

If this function is not defined, it is assumed that the scan must take place within the parallel leader. Note that returning `true` does not mean that the scan itself can be done in parallel, only that the scan can be performed within a parallel worker. Therefore, it can be useful to define this method even when parallel execution is not supported.

```
Size
EstimateDSMForeignScan(ForeignScanState *node, ParallelContext *pcxt);
```

Estimate the amount of dynamic shared memory that will be required for parallel operation. This may be higher than the amount that will actually be used, but it must not be lower. The return value is in bytes. This function is optional, and can be omitted if not needed; but if it is omitted, the next three functions must be omitted as well, because no shared memory will be allocated for the FDW's use.

```
void
InitializeDSMForeignScan(ForeignScanState *node, ParallelContext *pcxt,
                        void *coordinate);
```

Initialize the dynamic shared memory that will be required for parallel operation. `coordinate` points to a shared memory area of size equal to the return value of `EstimateDSMForeignScan`. This function is optional, and can be omitted if not needed.

```
void
ReInitializeDSMForeignScan(ForeignScanState *node, ParallelContext *pcxt,
                          void *coordinate);
```

Re-initialize the dynamic shared memory required for parallel operation when the foreign-scan plan node is about to be re-scanned. This function is optional, and can be omitted if not needed. Recommended practice is that this function reset only shared state, while the `ReScanForeignScan` function resets only local state. Currently, this function will be called before `ReScanForeignScan`, but it's best not to rely on that ordering.

```
void
InitializeWorkerForeignScan(ForeignScanState *node, shm_toc *toc,
                          void *coordinate);
```

Initialize a parallel worker's local state based on the shared state set up by the leader during `InitializeDSMForeignScan`. This function is optional, and can be omitted if not needed.

```
void
ShutdownForeignScan(ForeignScanState *node);
```

Release resources when it is anticipated the node will not be executed to completion. This is not called in all cases; sometimes, `EndForeignScan` may be called without this function having been called first. Since the DSM segment used by parallel query is destroyed just after this callback is invoked, foreign data wrappers that wish to take some action before the DSM segment goes away should implement this method.

## 52.2.10. FDW Routines for Reparameterization of Paths

```
List *
ReparameterizeForeignPathByChild(PlannerInfo *root, List *fdw_private,
                                RelOptInfo *child_rel);
```

This function is called while converting a path parameterized by the top-most parent of the given child relation `child_rel` to be parameterized by the child relation. The function is used to reparameterize any paths or translate any expression nodes saved in the given `fdw_private` member of a `ForeignPath`. The callback may use `reparameterize_path_by_child`, `adjust_appendrel_attrs` or `adjust_appendrel_attrs_multilevel` as required.

## 52.3. Foreign Data Wrapper Helper Functions

Several helper functions are exported from the core server so that authors of foreign data wrappers can get easy access to attributes of FDW-related objects, such as FDW options. To use any of these functions, you need to include the header file `foreign/foreign.h` in your source file. That header also defines the struct types that are returned by these functions.

```
ForeignDataWrapper *
GetForeignDataWrapperExtended(Oid fdwid, bits16 flags);
```

This function returns a `ForeignDataWrapper` object for the foreign-data wrapper with the given OID. A `ForeignDataWrapper` object contains properties of the FDW (see `foreign/foreign.h` for details). `flags` is a bitwise-or'd bit mask indicating an extra set of options. It can take the value `FDW_MISSING_OK`, in which case a `NULL` result is returned to the caller instead of an error for an undefined object.

```
ForeignDataWrapper *
```

```
GetForeignDataWrapper(Oid fdwid);
```

This function returns a `ForeignDataWrapper` object for the foreign-data wrapper with the given OID. A `ForeignDataWrapper` object contains properties of the FDW (see `foreign/foreign.h` for details).

```
ForeignServer *
GetForeignServerExtended(Oid serverid, bits16 flags);
```

This function returns a `ForeignServer` object for the foreign server with the given OID. A `ForeignServer` object contains properties of the server (see `foreign/foreign.h` for details). `flags` is a bitwise-or'd bit mask indicating an extra set of options. It can take the value `FSV_MISSING_OK`, in which case a `NULL` result is returned to the caller instead of an error for an undefined object.

```
ForeignServer *
GetForeignServer(Oid serverid);
```

This function returns a `ForeignServer` object for the foreign server with the given OID. A `ForeignServer` object contains properties of the server (see `foreign/foreign.h` for details).

```
UserMapping *
GetUserMapping(Oid userid, Oid serverid);
```

This function returns a `UserMapping` object for the user mapping of the given role on the given server. (If there is no mapping for the specific user, it will return the mapping for `PUBLIC`, or throw error if there is none.) A `UserMapping` object contains properties of the user mapping (see `foreign/foreign.h` for details).

```
ForeignTable *
GetForeignTable(Oid relid);
```

This function returns a `ForeignTable` object for the foreign table with the given OID. A `ForeignTable` object contains properties of the foreign table (see `foreign/foreign.h` for details).

```
List *
GetForeignColumnOptions(Oid relid, AttrNumber attnum);
```

This function returns the per-column FDW options for the column with the given foreign table OID and attribute number, in the form of a list of `DefElem`. `NIL` is returned if the column has no options.

Some object types have name-based lookup functions in addition to the OID-based ones:

```
ForeignDataWrapper *
GetForeignDataWrapperByName(const char *name, bool missing_ok);
```

This function returns a `ForeignDataWrapper` object for the foreign-data wrapper with the given name. If the wrapper is not found, return `NULL` if `missing_ok` is true, otherwise raise an error.

```
ForeignServer *
GetForeignServerByName(const char *name, bool missing_ok);
```

This function returns a `ForeignServer` object for the foreign server with the given name. If the server is not found, return `NULL` if `missing_ok` is true, otherwise raise an error.

## 52.4. Foreign Data Wrapper Query Planning

The FDW callback functions `GetForeignRelSize`, `GetForeignPaths`, `GetForeignPlan`, `PlanForeignModify`, `GetForeignJoinPaths`, `GetForeignUpperPaths`, and `PlanDirectModify` must fit into the workings of the Postgres Pro planner. Here are some notes about what they must do.

The information in `root` and `baserel` can be used to reduce the amount of information that has to be fetched from the foreign table (and therefore reduce the cost). `baserel->baserestrictinfo` is particularly interesting, as it contains restriction quals (`WHERE` clauses) that should be used to filter the

rows to be fetched. (The FDW itself is not required to enforce these quals, as the core executor can check them instead.) `baserel->reftarget->exprs` can be used to determine which columns need to be fetched; but note that it only lists columns that have to be emitted by the `ForeignScan` plan node, not columns that are used in qual evaluation but not output by the query.

Various private fields are available for the FDW planning functions to keep information in. Generally, whatever you store in FDW private fields should be `palloc'd`, so that it will be reclaimed at the end of planning.

`baserel->fdw_private` is a `void` pointer that is available for FDW planning functions to store information relevant to the particular foreign table. The core planner does not touch it except to initialize it to `NULL` when the `RelOptInfo` node is created. It is useful for passing information forward from `GetForeignRelSize` to `GetForeignPaths` and/or `GetForeignPaths` to `GetForeignPlan`, thereby avoiding recalculation.

`GetForeignPaths` can identify the meaning of different access paths by storing private information in the `fdw_private` field of `ForeignPath` nodes. `fdw_private` is declared as a `List` pointer, but could actually contain anything since the core planner does not touch it. However, best practice is to use a representation that's dumpable by `nodeToString`, for use with debugging support available in the backend.

`GetForeignPlan` can examine the `fdw_private` field of the selected `ForeignPath` node, and can generate `fdw_exprs` and `fdw_private` lists to be placed in the `ForeignScan` plan node, where they will be available at execution time. Both of these lists must be represented in a form that `copyObject` knows how to copy. The `fdw_private` list has no other restrictions and is not interpreted by the core backend in any way. The `fdw_exprs` list, if not `NIL`, is expected to contain expression trees that are intended to be executed at run time. These trees will undergo post-processing by the planner to make them fully executable.

In `GetForeignPlan`, generally the passed-in target list can be copied into the plan node as-is. The passed `scan_clauses` list contains the same clauses as `baserel->baserestrictinfo`, but may be re-ordered for better execution efficiency. In simple cases the FDW can just strip `RestrictInfo` nodes from the `scan_clauses` list (using `extract_actual_clauses`) and put all the clauses into the plan node's qual list, which means that all the clauses will be checked by the executor at run time. More complex FDWs may be able to check some of the clauses internally, in which case those clauses can be removed from the plan node's qual list so that the executor doesn't waste time rechecking them.

As an example, the FDW might identify some restriction clauses of the form `foreign_variable = sub_expression`, which it determines can be executed on the remote server given the locally-evaluated value of the `sub_expression`. The actual identification of such a clause should happen during `GetForeignPaths`, since it would affect the cost estimate for the path. The path's `fdw_private` field would probably include a pointer to the identified clause's `RestrictInfo` node. Then `GetForeignPlan` would remove that clause from `scan_clauses`, but add the `sub_expression` to `fdw_exprs` to ensure that it gets massaged into executable form. It would probably also put control information into the plan node's `fdw_private` field to tell the execution functions what to do at run time. The query transmitted to the remote server would involve something like `WHERE foreign_variable = $1`, with the parameter value obtained at run time from evaluation of the `fdw_exprs` expression tree.

Any clauses removed from the plan node's qual list must instead be added to `fdw_recheck_quals` or rechecked by `RecheckForeignScan` in order to ensure correct behavior at the `READ COMMITTED` isolation level. When a concurrent update occurs for some other table involved in the query, the executor may need to verify that all of the original quals are still satisfied for the tuple, possibly against a different set of parameter values. Using `fdw_recheck_quals` is typically easier than implementing checks inside `RecheckForeignScan`, but this method will be insufficient when outer joins have been pushed down, since the join tuples in that case might have some fields go to `NULL` without rejecting the tuple entirely.

Another `ForeignScan` field that can be filled by FDWs is `fdw_scan_tlist`, which describes the tuples returned by the FDW for this plan node. For simple foreign table scans this can be set to `NIL`, implying that the returned tuples have the row type declared for the foreign table. A non-`NIL` value must be a

target list (list of `TargetEntry`s) containing `Vars` and/or expressions representing the returned columns. This might be used, for example, to show that the FDW has omitted some columns that it noticed won't be needed for the query. Also, if the FDW can compute expressions used by the query more cheaply than can be done locally, it could add those expressions to `fdw_scan_tlist`. Note that join plans (created from paths made by `GetForeignJoinPaths`) must always supply `fdw_scan_tlist` to describe the set of columns they will return.

The FDW should always construct at least one path that depends only on the table's restriction clauses. In join queries, it might also choose to construct path(s) that depend on join clauses, for example `foreign_variable = local_variable`. Such clauses will not be found in `baserel->baserestrictinfo` but must be sought in the relation's join lists. A path using such a clause is called a "parameterized path". It must identify the other relations used in the selected join clause(s) with a suitable value of `param_info`; use `get_baserel_parampathinfo` to compute that value. In `GetForeignPlan`, the `local_variable` portion of the join clause would be added to `fdw_exprs`, and then at run time the case works the same as for an ordinary restriction clause.

If an FDW supports remote joins, `GetForeignJoinPaths` should produce `ForeignPaths` for potential remote joins in much the same way as `GetForeignPaths` works for base tables. Information about the intended join can be passed forward to `GetForeignPlan` in the same ways described above. However, `baserestrictinfo` is not relevant for join relations; instead, the relevant join clauses for a particular join are passed to `GetForeignJoinPaths` as a separate parameter (`extra->restrictlist`).

An FDW might additionally support direct execution of some plan actions that are above the level of scans and joins, such as grouping or aggregation. To offer such options, the FDW should generate paths and insert them into the appropriate *upper relation*. For example, a path representing remote aggregation should be inserted into the `UPPERREL_GROUP_AGG` relation, using `add_path`. This path will be compared on a cost basis with local aggregation performed by reading a simple scan path for the foreign relation (note that such a path must also be supplied, else there will be an error at plan time). If the remote-aggregation path wins, which it usually would, it will be converted into a plan in the usual way, by calling `GetForeignPlan`. The recommended place to generate such paths is in the `GetForeignUpperPaths` callback function, which is called for each upper relation (i.e., each post-scan/join processing step), if all the base relations of the query come from the same FDW.

`PlanForeignModify` and the other callbacks described in [Section 52.2.4](#) are designed around the assumption that the foreign relation will be scanned in the usual way and then individual row updates will be driven by a local `ModifyTable` plan node. This approach is necessary for the general case where an update requires reading local tables as well as foreign tables. However, if the operation could be executed entirely by the foreign server, the FDW could generate a path representing that and insert it into the `UPPERREL_FINAL` upper relation, where it would compete against the `ModifyTable` approach. This approach could also be used to implement remote `SELECT FOR UPDATE`, rather than using the row locking callbacks described in [Section 52.2.5](#). Keep in mind that a path inserted into `UPPERREL_FINAL` is responsible for implementing *all* behavior of the query.

When planning an `UPDATE` or `DELETE`, `PlanForeignModify` and `PlanDirectModify` can look up the `RelOptInfo` struct for the foreign table and make use of the `baserel->fdw_private` data previously created by the scan-planning functions. However, in `INSERT` the target table is not scanned so there is no `RelOptInfo` for it. The `List` returned by `PlanForeignModify` has the same restrictions as the `fdw_private` list of a `ForeignScan` plan node, that is it must contain only structures that `copyObject` knows how to copy.

`INSERT` with an `ON CONFLICT` clause does not support specifying the conflict target, as unique constraints or exclusion constraints on remote tables are not locally known. This in turn implies that `ON CONFLICT DO UPDATE` is not supported, since the specification is mandatory there.

## 52.5. Row Locking in Foreign Data Wrappers

If an FDW's underlying storage mechanism has a concept of locking individual rows to prevent concurrent updates of those rows, it is usually worthwhile for the FDW to perform row-level locking with

as close an approximation as practical to the semantics used in ordinary Postgres Pro tables. There are multiple considerations involved in this.

One key decision to be made is whether to perform *early locking* or *late locking*. In early locking, a row is locked when it is first retrieved from the underlying store, while in late locking, the row is locked only when it is known that it needs to be locked. (The difference arises because some rows may be discarded by locally-checked restriction or join conditions.) Early locking is much simpler and avoids extra round trips to a remote store, but it can cause locking of rows that need not have been locked, resulting in reduced concurrency or even unexpected deadlocks. Also, late locking is only possible if the row to be locked can be uniquely re-identified later. Preferably the row identifier should identify a specific version of the row, as Postgres Pro TIDs do.

By default, Postgres Pro ignores locking considerations when interfacing to FDWs, but an FDW can perform early locking without any explicit support from the core code. The API functions described in [Section 52.2.5](#), which were added in Postgres Pro 9.5, allow an FDW to use late locking if it wishes.

An additional consideration is that in `READ COMMITTED` isolation mode, Postgres Pro may need to re-check restriction and join conditions against an updated version of some target tuple. Rechecking join conditions requires re-obtaining copies of the non-target rows that were previously joined to the target tuple. When working with standard Postgres Pro tables, this is done by including the TIDs of the non-target tables in the column list projected through the join, and then re-fetching non-target rows when required. This approach keeps the join data set compact, but it requires inexpensive re-fetch capability, as well as a TID that can uniquely identify the row version to be re-fetched. By default, therefore, the approach used with foreign tables is to include a copy of the entire row fetched from a foreign table in the column list projected through the join. This puts no special demands on the FDW but can result in reduced performance of merge and hash joins. An FDW that is capable of meeting the re-fetch requirements can choose to do it the first way.

For an `UPDATE` or `DELETE` on a foreign table, it is recommended that the `ForeignScan` operation on the target table perform early locking on the rows that it fetches, perhaps via the equivalent of `SELECT FOR UPDATE`. An FDW can detect whether a table is an `UPDATE/DELETE` target at plan time by comparing its `relid` to `root->parse->resultRelation`, or at execution time by using `ExecRelationIsTargetRelation()`. An alternative possibility is to perform late locking within the `ExecForeignUpdate` or `ExecForeignDelete` callback, but no special support is provided for this.

For foreign tables that are specified to be locked by a `SELECT FOR UPDATE/SHARE` command, the `ForeignScan` operation can again perform early locking by fetching tuples with the equivalent of `SELECT FOR UPDATE/SHARE`. To perform late locking instead, provide the callback functions defined in [Section 52.2.5](#). In `GetForeignRowMarkType`, select rowmark option `ROW_MARK_EXCLUSIVE`, `ROW_MARK_NOKEYEXCLUSIVE`, `ROW_MARK_SHARE`, or `ROW_MARK_KEYSHARE` depending on the requested lock strength. (The core code will act the same regardless of which of these four options you choose.) Elsewhere, you can detect whether a foreign table was specified to be locked by this type of command by using `get_plan_rowmark` at plan time, or `ExecFindRowMark` at execution time; you must check not only whether a non-null rowmark struct is returned, but that its `strength` field is not `LCS_NONE`.

Lastly, for foreign tables that are used in an `UPDATE`, `DELETE` or `SELECT FOR UPDATE/SHARE` command but are not specified to be row-locked, you can override the default choice to copy entire rows by having `GetForeignRowMarkType` select option `ROW_MARK_REFERENCE` when it sees lock strength `LCS_NONE`. This will cause `RefetchForeignRow` to be called with that value for `markType`; it should then re-fetch the row without acquiring any new lock. (If you have a `GetForeignRowMarkType` function but don't wish to re-fetch unlocked rows, select option `ROW_MARK_COPY` for `LCS_NONE`.)

---

# Chapter 53. Writing a Table Sampling Method

Postgres Pro's implementation of the `TABLESAMPLE` clause supports custom table sampling methods, in addition to the `BERNOULLI` and `SYSTEM` methods that are required by the SQL standard. The sampling method determines which rows of the table will be selected when the `TABLESAMPLE` clause is used.

At the SQL level, a table sampling method is represented by a single SQL function, typically implemented in C, having the signature

```
method_name(internal) RETURNS tsm_handler
```

The name of the function is the same method name appearing in the `TABLESAMPLE` clause. The `internal` argument is a dummy (always having value zero) that simply serves to prevent this function from being called directly from a SQL command. The result of the function must be a palloc'd struct of type `TsmRoutine`, which contains pointers to support functions for the sampling method. These support functions are plain C functions and are not visible or callable at the SQL level. The support functions are described in [Section 53.1](#).

In addition to function pointers, the `TsmRoutine` struct must provide these additional fields:

```
List *parameterTypes
```

This is an OID list containing the data type OIDs of the parameter(s) that will be accepted by the `TABLESAMPLE` clause when this sampling method is used. For example, for the built-in methods, this list contains a single item with value `FLOAT4OID`, which represents the sampling percentage. Custom sampling methods can have more or different parameters.

```
bool repeatable_across_queries
```

If `true`, the sampling method can deliver identical samples across successive queries, if the same parameters and `REPEATABLE` seed value are supplied each time and the table contents have not changed. When this is `false`, the `REPEATABLE` clause is not accepted for use with the sampling method.

```
bool repeatable_across_scans
```

If `true`, the sampling method can deliver identical samples across successive scans in the same query (assuming unchanging parameters, seed value, and snapshot). When this is `false`, the planner will not select plans that would require scanning the sampled table more than once, since that might result in inconsistent query output.

The table sampling methods included in the standard distribution are good references when trying to write your own. Look into the `contrib` subdirectory for add-on methods.

## 53.1. Sampling Method Support Functions

The TSM handler function returns a palloc'd `TsmRoutine` struct containing pointers to the support functions described below. Most of the functions are required, but some are optional, and those pointers can be `NULL`.

```
void  
SampleScanGetSampleSize (PlannerInfo *root,  
                          RelOptInfo *baserel,  
                          List *paramexprs,  
                          BlockNumber *pages,  
                          double *tuples);
```

This function is called during planning. It must estimate the number of relation pages that will be read during a sample scan, and the number of tuples that will be selected by the scan. (For example, these

might be determined by estimating the sampling fraction, and then multiplying the `basere1->pages` and `basere1->tuples` numbers by that, being sure to round the results to integral values.) The `paramexprs` list holds the expression(s) that are parameters to the `TABLESAMPLE` clause. It is recommended to use `estimate_expression_value()` to try to reduce these expressions to constants, if their values are needed for estimation purposes; but the function must provide size estimates even if they cannot be reduced, and it should not fail even if the values appear invalid (remember that they're only estimates of what the run-time values will be). The `pages` and `tuples` parameters are outputs.

```
void
InitSampleScan (SampleScanState *node,
                int eflags);
```

Initialize for execution of a `SampleScan` plan node. This is called during executor startup. It should perform any initialization needed before processing can start. The `SampleScanState` node has already been created, but its `tsm_state` field is `NULL`. The `InitSampleScan` function can `malloc` whatever internal state data is needed by the sampling method, and store a pointer to it in `node->tsm_state`. Information about the table to scan is accessible through other fields of the `SampleScanState` node (but note that the `node->ss.ss_currentScanDesc` scan descriptor is not set up yet). `eflags` contains flag bits describing the executor's operating mode for this plan node.

When `(eflags & EXEC_FLAG_EXPLAIN_ONLY)` is true, the scan will not actually be performed, so this function should only do the minimum required to make the node state valid for `EXPLAIN` and `EndSampleScan`.

This function can be omitted (set the pointer to `NULL`), in which case `BeginSampleScan` must perform all initialization needed by the sampling method.

```
void
BeginSampleScan (SampleScanState *node,
                 Datum *params,
                 int nparams,
                 uint32 seed);
```

Begin execution of a sampling scan. This is called just before the first attempt to fetch a tuple, and may be called again if the scan needs to be restarted. Information about the table to scan is accessible through fields of the `SampleScanState` node (but note that the `node->ss.ss_currentScanDesc` scan descriptor is not set up yet). The `params` array, of length `nparams`, contains the values of the parameters supplied in the `TABLESAMPLE` clause. These will have the number and types specified in the sampling method's `parameterTypes` list, and have been checked to not be null. `seed` contains a seed to use for any random numbers generated within the sampling method; it is either a hash derived from the `REPEATABLE` value if one was given, or the result of `random()` if not.

This function may adjust the fields `node->use_bulkread` and `node->use_pagemode`. If `node->use_bulkread` is true, which it is by default, the scan will use a buffer access strategy that encourages recycling buffers after use. It might be reasonable to set this to `false` if the scan will visit only a small fraction of the table's pages. If `node->use_pagemode` is true, which it is by default, the scan will perform visibility checking in a single pass for all tuples on each visited page. It might be reasonable to set this to `false` if the scan will select only a small fraction of the tuples on each visited page. That will result in fewer tuple visibility checks being performed, though each one will be more expensive because it will require more locking.

If the sampling method is marked `repeatable_across_scans`, it must be able to select the same set of tuples during a rescan as it did originally, that is a fresh call of `BeginSampleScan` must lead to selecting the same tuples as before (if the `TABLESAMPLE` parameters and seed don't change).

```
BlockNumber
NextSampleBlock (SampleScanState *node, BlockNumber nblocks);
```

Returns the block number of the next page to be scanned, or `InvalidBlockNumber` if no pages remain to be scanned.

This function can be omitted (set the pointer to NULL), in which case the core code will perform a sequential scan of the entire relation. Such a scan can use synchronized scanning, so that the sampling method cannot assume that the relation pages are visited in the same order on each scan.

```
OffsetNumber  
NextSampleTuple (SampleScanState *node,  
                 BlockNumber blockno,  
                 OffsetNumber maxoffset);
```

Returns the offset number of the next tuple to be sampled on the specified page, or `InvalidOffsetNumber` if no tuples remain to be sampled. `maxoffset` is the largest offset number in use on the page.

### Note

`NextSampleTuple` is not explicitly told which of the offset numbers in the range 1 .. `maxoffset` actually contain valid tuples. This is not normally a problem since the core code ignores requests to sample missing or invisible tuples; that should not result in any bias in the sample. However, if necessary, the function can use `node->donetuples` to examine how many of the tuples it returned were valid and visible.

### Note

`NextSampleTuple` must *not* assume that `blockno` is the same page number returned by the most recent `NextSampleBlock` call. It was returned by some previous `NextSampleBlock` call, but the core code is allowed to call `NextSampleBlock` in advance of actually scanning pages, so as to support prefetching. It is OK to assume that once sampling of a given page begins, successive `NextSampleTuple` calls all refer to the same page until `InvalidOffsetNumber` is returned.

```
void  
EndSampleScan (SampleScanState *node);
```

End the scan and release resources. It is normally not important to release `malloc`'d memory, but any externally-visible resources should be cleaned up. This function can be omitted (set the pointer to NULL) in the common case where no such resources exist.

---

# Chapter 54. Writing a Custom Scan Provider

Postgres Pro supports a set of experimental facilities which are intended to allow extension modules to add new scan types to the system. Unlike a [foreign data wrapper](#), which is only responsible for knowing how to scan its own foreign tables, a custom scan provider can provide an alternative method of scanning any relation in the system. Typically, the motivation for writing a custom scan provider will be to allow the use of some optimization not supported by the core system, such as caching or some form of hardware acceleration. This chapter outlines how to write a new custom scan provider.

Implementing a new type of custom scan is a three-step process. First, during planning, it is necessary to generate access paths representing a scan using the proposed strategy. Second, if one of those access paths is selected by the planner as the optimal strategy for scanning a particular relation, the access path must be converted to a plan. Finally, it must be possible to execute the plan and generate the same results that would have been generated for any other access path targeting the same relation.

## 54.1. Creating Custom Scan Paths

A custom scan provider will typically add paths for a base relation by setting the following hook, which is called after the core code has generated all the access paths it can for the relation (except for Gather paths, which are made after this call so that they can use partial paths added by the hook):

```
typedef void (*set_rel_pathlist_hook_type) (PlannerInfo *root,
                                           RelOptInfo *rel,
                                           Index rti,
                                           RangeTblEntry *rte);

extern PGDLLIMPORT set_rel_pathlist_hook_type set_rel_pathlist_hook;
```

Although this hook function can be used to examine, modify, or remove paths generated by the core system, a custom scan provider will typically confine itself to generating `CustomPath` objects and adding them to `rel` using `add_path`. The custom scan provider is responsible for initializing the `CustomPath` object, which is declared like this:

```
typedef struct CustomPath
{
    Path      path;
    uint32    flags;
    List      *custom_paths;
    List      *custom_private;
    const CustomPathMethods *methods;
} CustomPath;
```

`path` must be initialized as for any other path, including the row-count estimate, start and total cost, and sort ordering provided by this path. `flags` is a bit mask, which should include `CUSTOMPATH_SUPPORT_BACKWARD_SCAN` if the custom path can support a backward scan and `CUSTOMPATH_SUPPORT_MARK_RESTORE` if it can support mark and restore. Both capabilities are optional. An optional `custom_paths` is a list of `Path` nodes used by this custom-path node; these will be transformed into `Plan` nodes by planner. `custom_private` can be used to store the custom path's private data. Private data should be stored in a form that can be handled by `nodeToString`, so that debugging routines that attempt to print the custom path will work as designed. `methods` must point to a (usually statically allocated) object implementing the required custom path methods, of which there is currently only one.

A custom scan provider can also provide join paths. Just as for base relations, such a path must produce the same output as would normally be produced by the join it replaces. To do this, the join provider should set the following hook, and then within the hook function, create `CustomPath` path(s) for the join relation.

```
typedef void (*set_join_pathlist_hook_type) (PlannerInfo *root,
                                             RelOptInfo *joinrel,
                                             RelOptInfo *outerrel,
                                             RelOptInfo *innerrel,
                                             JoinType jointype,
```

```

JoinPathExtraData *extra);
extern PGDLLIMPORT set_join_pathlist_hook_type set_join_pathlist_hook;

```

This hook will be invoked repeatedly for the same join relation, with different combinations of inner and outer relations; it is the responsibility of the hook to minimize duplicated work.

### 54.1.1. Custom Scan Path Callbacks

```

Plan *(*PlanCustomPath) (PlannerInfo *root,
                          RelOptInfo *rel,
                          CustomPath *best_path,
                          List *tlist,
                          List *clauses,
                          List *custom_plans);

```

Convert a custom path to a finished plan. The return value will generally be a `CustomScan` object, which the callback must allocate and initialize. See [Section 54.2](#) for more details.

## 54.2. Creating Custom Scan Plans

A custom scan is represented in a finished plan tree using the following structure:

```

typedef struct CustomScan
{
    Scan        scan;
    uint32     flags;
    List        *custom_plans;
    List        *custom_exprs;
    List        *custom_private;
    List        *custom_scan_tlist;
    Bitmapset   *custom_relids;
    const CustomScanMethods *methods;
} CustomScan;

```

`scan` must be initialized as for any other scan, including estimated costs, target lists, qualifications, and so on. `flags` is a bit mask with the same meaning as in `CustomPath`. `custom_plans` can be used to store child `Plan` nodes. `custom_exprs` should be used to store expression trees that will need to be fixed up by `setrefs.c` and `subselect.c`, while `custom_private` should be used to store other private data that is only used by the custom scan provider itself. `custom_scan_tlist` can be `NIL` when scanning a base relation, indicating that the custom scan returns scan tuples that match the base relation's row type. Otherwise it is a target list describing the actual scan tuples. `custom_scan_tlist` must be provided for joins, and could be provided for scans if the custom scan provider can compute some non-Var expressions. `custom_relids` is set by the core code to the set of relations (range table indexes) that this scan node handles; except when this scan is replacing a join, it will have only one member. `methods` must point to a (usually statically allocated) object implementing the required custom scan methods, which are further detailed below.

When a `CustomScan` scans a single relation, `scan.scanrelid` must be the range table index of the table to be scanned. When it replaces a join, `scan.scanrelid` should be zero.

Plan trees must be able to be duplicated using `copyObject`, so all the data stored within the “custom” fields must consist of nodes that that function can handle. Furthermore, custom scan providers cannot substitute a larger structure that embeds a `CustomScan` for the structure itself, as would be possible for a `CustomPath` or `CustomScanState`.

### 54.2.1. Custom Scan Plan Callbacks

```

Node *(*CreateCustomScanState) (CustomScan *cscan);

```

Allocate a `CustomScanState` for this `CustomScan`. The actual allocation will often be larger than required for an ordinary `CustomScanState`, because many providers will wish to embed that as the first field of

a larger structure. The value returned must have the `node` tag and `methods` set appropriately, but other fields should be left as zeroes at this stage; after `ExecInitCustomScan` performs basic initialization, the `BeginCustomScan` callback will be invoked to give the custom scan provider a chance to do whatever else is needed.

## 54.3. Executing Custom Scans

When a `CustomScan` is executed, its execution state is represented by a `CustomScanState`, which is declared as follows:

```
typedef struct CustomScanState
{
    ScanState ss;
    uint32    flags;
    const CustomExecMethods *methods;
} CustomScanState;
```

`ss` is initialized as for any other scan state, except that if the scan is for a join rather than a base relation, `ss.ss_currentRelation` is left `NULL`. `flags` is a bit mask with the same meaning as in `CustomPath` and `CustomScan`. `methods` must point to a (usually statically allocated) object implementing the required custom scan state methods, which are further detailed below. Typically, a `CustomScanState`, which need not support `copyObject`, will actually be a larger structure embedding the above as its first member.

### 54.3.1. Custom Scan Execution Callbacks

```
void (*BeginCustomScan) (CustomScanState *node,
                        EState *estate,
                        int eflags);
```

Complete initialization of the supplied `CustomScanState`. Standard fields have been initialized by `ExecInitCustomScan`, but any private fields should be initialized here.

```
TupleTableSlot *(*ExecCustomScan) (CustomScanState *node);
```

Fetch the next scan tuple. If any tuples remain, it should fill `ps_ResultTupleSlot` with the next tuple in the current scan direction, and then return the tuple slot. If not, `NULL` or an empty slot should be returned.

```
void (*EndCustomScan) (CustomScanState *node);
```

Clean up any private data associated with the `CustomScanState`. This method is required, but it does not need to do anything if there is no associated data or it will be cleaned up automatically.

```
void (*ReScanCustomScan) (CustomScanState *node);
```

Rewind the current scan to the beginning and prepare to rescan the relation.

```
void (*MarkPosCustomScan) (CustomScanState *node);
```

Save the current scan position so that it can subsequently be restored by the `RestrPosCustomScan` callback. This callback is optional, and need only be supplied if the `CUSTOMPATH_SUPPORT_MARK_RESTORE` flag is set.

```
void (*RestrPosCustomScan) (CustomScanState *node);
```

Restore the previous scan position as saved by the `MarkPosCustomScan` callback. This callback is optional, and need only be supplied if the `CUSTOMPATH_SUPPORT_MARK_RESTORE` flag is set.

```
Size (*EstimateDSMCustomScan) (CustomScanState *node,
                              ParallelContext *pcxt);
```

Estimate the amount of dynamic shared memory that will be required for parallel operation. This may be higher than the amount that will actually be used, but it must not be lower. The return value is in bytes. This callback is optional, and need only be supplied if this custom scan provider supports parallel execution.

```
void (*InitializeDSMCustomScan) (CustomScanState *node,  
                                ParallelContext *pcxt,  
                                void *coordinate);
```

Initialize the dynamic shared memory that will be required for parallel operation. `coordinate` points to a shared memory area of size equal to the return value of `EstimateDSMCustomScan`. This callback is optional, and need only be supplied if this custom scan provider supports parallel execution.

```
void (*ReInitializeDSMCustomScan) (CustomScanState *node,  
                                   ParallelContext *pcxt,  
                                   void *coordinate);
```

Re-initialize the dynamic shared memory required for parallel operation when the custom-scan plan node is about to be re-scanned. This callback is optional, and need only be supplied if this custom scan provider supports parallel execution. Recommended practice is that this callback reset only shared state, while the `ReScanCustomScan` callback resets only local state. Currently, this callback will be called before `ReScanCustomScan`, but it's best not to rely on that ordering.

```
void (*InitializeWorkerCustomScan) (CustomScanState *node,  
                                    shm_toc *toc,  
                                    void *coordinate);
```

Initialize a parallel worker's local state based on the shared state set up by the leader during `InitializeDSMCustomScan`. This callback is optional, and need only be supplied if this custom scan provider supports parallel execution.

```
void (*ShutdownCustomScan) (CustomScanState *node);
```

Release resources when it is anticipated the node will not be executed to completion. This is not called in all cases; sometimes, `EndCustomScan` may be called without this function having been called first. Since the DSM segment used by parallel query is destroyed just after this callback is invoked, custom scan providers that wish to take some action before the DSM segment goes away should implement this method.

```
void (*ExplainCustomScan) (CustomScanState *node,  
                           List *ancestors,  
                           ExplainState *es);
```

Output additional information for `EXPLAIN` of a custom-scan plan node. This callback is optional. Common data stored in the `ScanState`, such as the target list and scan relation, will be shown even without this callback, but the callback allows the display of additional, private state.

# Chapter 55. Genetic Query Optimizer

## Author

Written by Martin Utesch (<utesch@aut.tu-freiberg.de>) for the Institute of Automatic Control at the University of Mining and Technology in Freiberg, Germany.

## 55.1. Query Handling as a Complex Optimization Problem

Among all relational operators the most difficult one to process and optimize is the *join*. The number of possible query plans grows exponentially with the number of joins in the query. Further optimization effort is caused by the support of a variety of *join methods* (e.g., nested loop, hash join, merge join in Postgres Pro) to process individual joins and a diversity of *indexes* (e.g., B-tree, hash, GiST and GIN in Postgres Pro) as access paths for relations.

The normal Postgres Pro query optimizer performs a *near-exhaustive search* over the space of alternative strategies. This algorithm, first introduced in IBM's System R database, produces a near-optimal join order, but can take an enormous amount of time and memory space when the number of joins in the query grows large. This makes the ordinary Postgres Pro query optimizer inappropriate for queries that join a large number of tables.

The Institute of Automatic Control at the University of Mining and Technology, in Freiberg, Germany, encountered some problems when it wanted to use PostgreSQL as the backend for a decision support knowledge based system for the maintenance of an electrical power grid. The DBMS needed to handle large join queries for the inference machine of the knowledge based system. The number of joins in these queries made using the normal query optimizer infeasible.

In the following we describe the implementation of a *genetic algorithm* to solve the join ordering problem in a manner that is efficient for queries involving large numbers of joins.

## 55.2. Genetic Algorithms

The genetic algorithm (GA) is a heuristic optimization method which operates through randomized search. The set of possible solutions for the optimization problem is considered as a *population* of *individuals*. The degree of adaptation of an individual to its environment is specified by its *fitness*.

The coordinates of an individual in the search space are represented by *chromosomes*, in essence a set of character strings. A *gene* is a subsection of a chromosome which encodes the value of a single parameter being optimized. Typical encodings for a gene could be *binary* or *integer*.

Through simulation of the evolutionary operations *recombination*, *mutation*, and *selection* new generations of search points are found that show a higher average fitness than their ancestors. [Figure 55.1](#) illustrates these steps.

**Figure 55.1. Structure of a Genetic Algorithm**

According to the comp.ai.genetic FAQ it cannot be stressed too strongly that a GA is not a pure random search for a solution to a problem. A GA uses stochastic processes, but the result is distinctly non-random (better than random).

### 55.3. Genetic Query Optimization (GEQO) in Postgres Pro

The GEQO module approaches the query optimization problem as though it were the well-known traveling salesman problem (TSP). Possible query plans are encoded as integer strings. Each string represents the join order from one relation of the query to the next. For example, the join tree

```

  /\
 /\ 2
 /\ 3

```

4 1

is encoded by the integer string '4-1-3-2', which means, first join relation '4' and '1', then '3', and then '2', where 1, 2, 3, 4 are relation IDs within the Postgres Pro optimizer.

Specific characteristics of the GEQO implementation in Postgres Pro are:

- Usage of a *steady state* GA (replacement of the least fit individuals in a population, not whole-generational replacement) allows fast convergence towards improved query plans. This is essential for query handling with reasonable time;
- Usage of *edge recombination crossover* which is especially suited to keep edge losses low for the solution of the TSP by means of a GA;
- Mutation as genetic operator is deprecated so that no repair mechanisms are needed to generate legal TSP tours.

Parts of the GEQO module are adapted from D. Whitley's Genitor algorithm.

The GEQO module allows the Postgres Pro query optimizer to support large join queries effectively through non-exhaustive search.

### 55.3.1. Generating Possible Plans with GEQO

The GEQO planning process uses the standard planner code to generate plans for scans of individual relations. Then join plans are developed using the genetic approach. As shown above, each candidate join plan is represented by a sequence in which to join the base relations. In the initial stage, the GEQO code simply generates some possible join sequences at random. For each join sequence considered, the standard planner code is invoked to estimate the cost of performing the query using that join sequence. (For each step of the join sequence, all three possible join strategies are considered; and all the initially-determined relation scan plans are available. The estimated cost is the cheapest of these possibilities.) Join sequences with lower estimated cost are considered “more fit” than those with higher cost. The genetic algorithm discards the least fit candidates. Then new candidates are generated by combining genes of more-fit candidates — that is, by using randomly-chosen portions of known low-cost join sequences to create new sequences for consideration. This process is repeated until a preset number of join sequences have been considered; then the best one found at any time during the search is used to generate the finished plan.

This process is inherently nondeterministic, because of the randomized choices made during both the initial population selection and subsequent “mutation” of the best candidates. To avoid surprising changes of the selected plan, each run of the GEQO algorithm restarts its random number generator with the current `geqo_seed` parameter setting. As long as `geqo_seed` and the other GEQO parameters are kept fixed, the same plan will be generated for a given query (and other planner inputs such as statistics). To experiment with different search paths, try changing `geqo_seed`.

### 55.3.2. Future Implementation Tasks for PostgreSQL GEQO

Work is still needed to improve the genetic algorithm parameter settings. We have to find a compromise for the parameter settings to satisfy two competing demands:

- Optimality of the query plan
- Computing time

In the current implementation, the fitness of each candidate join sequence is estimated by running the standard planner's join selection and cost estimation code from scratch. To the extent that different candidates use similar sub-sequences of joins, a great deal of work will be repeated. This could be made significantly faster by retaining cost estimates for sub-joins. The problem is to avoid expending unreasonable amounts of memory on retaining that state.

At a more basic level, it is not clear that solving query optimization with a GA algorithm designed for TSP is appropriate. In the TSP case, the cost associated with any substring (partial tour) is independent of the rest of the tour, but this is certainly not true for query optimization. Thus it is questionable whether edge recombination crossover is the most effective mutation procedure.

# Chapter 56. Table Access Method Interface Definition

This chapter explains the interface between the core PostgreSQL system and *table access methods*, which manage the storage for tables. The core system knows little about these access methods beyond what is specified here, so it is possible to develop entirely new access method types by writing add-on code.

Each table access method is described by a row in the `pg_am` system catalog. The `pg_am` entry specifies a name and a *handler function* for the table access method. These entries can be created and deleted using the [CREATE ACCESS METHOD](#) and [DROP ACCESS METHOD](#) SQL commands.

A table access method handler function must be declared to accept a single argument of type `internal` and to return the pseudo-type `table_am_handler`. The argument is a dummy value that simply serves to prevent handler functions from being called directly from SQL commands. The result of the function must be a pointer to a struct of type `TableAmRoutine`, which contains everything that the core code needs to know to make use of the table access method. The return value needs to be of server lifetime, which is typically achieved by defining it as a `static const` variable in global scope. The `TableAmRoutine` struct, also called the access method's *API struct*, defines the behavior of the access method using callbacks. These callbacks are pointers to plain C functions and are not visible or callable at the SQL level. All the callbacks and their behavior is defined in the `TableAmRoutine` structure (with comments inside the struct defining the requirements for callbacks). Most callbacks have wrapper functions, which are documented from the point of view of a user (rather than an implementor) of the table access method. For details, please refer to the [src/include/access/tableam.h](#) file.

To implement an access method, an implementor will typically need to implement an AM-specific type of tuple table slot (see [src/include/executor/tuptable.h](#)), which allows code outside the access method to hold references to tuples of the AM, and to access the columns of the tuple.

Currently, the way an AM actually stores data is fairly unconstrained. For example, it's possible, but not required, to use postgres' shared buffer cache. In case it is used, it likely makes sense to use PostgreSQL's standard page layout as described in [Section 65.6](#).

One fairly large constraint of the table access method API is that, currently, if the AM wants to support modifications and/or indexes, it is necessary for each tuple to have a tuple identifier (TID) consisting of a block number and an item number (see also [Section 65.6](#)). It is not strictly necessary that the sub-parts of TIDs have the same meaning they e.g., have for `heap`, but if bitmap scan support is desired (it is optional), the block number needs to provide locality.

For crash safety, an AM can use postgres' [WAL](#), or a custom implementation. If WAL is chosen, either [Generic WAL Records](#) can be used, or a new type of WAL records can be implemented. Generic WAL Records are easy, but imply higher WAL volume. Implementation of a new type of WAL record currently requires modifications to core code (specifically, `src/include/access/rmgrlist.h`).

To implement transactional support in a manner that allows different table access methods be accessed within a single transaction, it likely is necessary to closely integrate with the machinery in `src/backend/access/transam/xlog.c`.

Any developer of a new table access method can refer to the existing `heap` implementation present in `src/backend/access/heap/heapam_handler.c` for details of its implementation.

---

# Chapter 57. Index Access Method Interface Definition

This chapter defines the interface between the core Postgres Pro system and *index access methods*, which manage individual index types. The core system knows nothing about indexes beyond what is specified here, so it is possible to develop entirely new index types by writing add-on code.

All indexes in Postgres Pro are what are known technically as *secondary indexes*; that is, the index is physically separate from the table file that it describes. Each index is stored as its own physical *relation* and so is described by an entry in the `pg_class` catalog. The contents of an index are entirely under the control of its index access method. In practice, all index access methods divide indexes into standard-size pages so that they can use the regular storage manager and buffer manager to access the index contents. (All the existing index access methods furthermore use the standard page layout described in [Section 65.6](#), and most use the same format for index tuple headers; but these decisions are not forced on an access method.)

An index is effectively a mapping from some data key values to *tuple identifiers*, or TIDs, of row versions (tuples) in the index's parent table. A TID consists of a block number and an item number within that block (see [Section 65.6](#)). This is sufficient information to fetch a particular row version from the table. Indexes are not directly aware that under MVCC, there might be multiple extant versions of the same logical row; to an index, each tuple is an independent object that needs its own index entry. Thus, an update of a row always creates all-new index entries for the row, even if the key values did not change. (HOT tuples are an exception to this statement; but indexes do not deal with those, either.) Index entries for dead tuples are reclaimed (by vacuuming) when the dead tuples themselves are reclaimed.

## 57.1. Basic API Structure for Indexes

Each index access method is described by a row in the `pg_am` system catalog. The `pg_am` entry specifies a name and a *handler function* for the index access method. These entries can be created and deleted using the [CREATE ACCESS METHOD](#) and [DROP ACCESS METHOD](#) SQL commands.

An index access method handler function must be declared to accept a single argument of type `internal` and to return the pseudo-type `index_am_handler`. The argument is a dummy value that simply serves to prevent handler functions from being called directly from SQL commands. The result of the function must be a palloc'd struct of type `IndexAmRoutine`, which contains everything that the core code needs to know to make use of the index access method. The `IndexAmRoutine` struct, also called the access method's *API struct*, includes fields specifying assorted fixed properties of the access method, such as whether it can support multicolumn indexes. More importantly, it contains pointers to support functions for the access method, which do all of the real work to access indexes. These support functions are plain C functions and are not visible or callable at the SQL level. The support functions are described in [Section 57.2](#).

The structure `IndexAmRoutine` is defined thus:

```
typedef struct IndexAmRoutine
{
    NodeTag      type;

    /*
     * Total number of strategies (operators) by which we can traverse/search
     * this AM. Zero if AM does not have a fixed set of strategy assignments.
     */
    uint16      amstrategies;
    /* total number of support functions that this AM uses */
    uint16      amsupport;
    /* opclass options support function number or 0 */
    uint16      amoptsprocnum;
    /* does AM support ORDER BY indexed column's value? */

```

## Index Access Method Interface Definition

---

```
bool        amcanorder;
/* does AM support ORDER BY result of an operator on indexed column? */
bool        amcanorderbyop;
/* does AM support backward scanning? */
bool        amcanbackward;
/* does AM support UNIQUE indexes? */
bool        amcanunique;
/* does AM support multi-column indexes? */
bool        amcanmulticol;
/* does AM require scans to have a constraint on the first index column? */
bool        amoptionalkey;
/* does AM handle ScalarArrayOpExpr quals? */
bool        amsearcharray;
/* does AM handle IS NULL/IS NOT NULL quals? */
bool        amsearchnulls;
/* can index storage data type differ from column data type? */
bool        amstorage;
/* can an index of this type be clustered on? */
bool        amclusterable;
/* does AM handle predicate locks? */
bool        ampredlocks;
/* does AM support parallel scan? */
bool        amcanparallel;
/* does AM support columns included with clause INCLUDE? */
bool        amcaninclude;
/* does AM use maintenance_work_mem? */
bool        amusemaintenanceworkmem;
/* OR of parallel vacuum flags */
uint8       amparallelvacuumoptions;
/* type of data stored in index, or InvalidOid if variable */
Oid         amkeytype;

/* interface functions */
ambuild_function ambuild;
ambuildempty_function ambuildempty;
aminert_function aminert;
ambulkdelete_function ambulkdelete;
amvacuumcleanup_function amvacuumcleanup;
amcanreturn_function amcanreturn; /* can be NULL */
amcostestimate_function amcostestimate;
amoptions_function amoptions;
amproperty_function amproperty; /* can be NULL */
ambuildphasename_function ambuildphasename; /* can be NULL */
amvalidate_function amvalidate;
ambeginscan_function ambeginscan;
amrescan_function amrescan;
amgettuple_function amgettuple; /* can be NULL */
amgetbitmap_function amgetbitmap; /* can be NULL */
amendscan_function amendscan;
ammarkpos_function ammarkpos; /* can be NULL */
amrestrpos_function amrestrpos; /* can be NULL */

/* interface functions to support parallel index scans */
amestimateparallelscan_function amestimateparallelscan; /* can be NULL */
aminrtparallelscan_function aminrtparallelscan; /* can be NULL */
amparallelrescan_function amparallelrescan; /* can be NULL */
} IndexAmRoutine;
```

To be useful, an index access method must also have one or more *operator families* and *operator classes* defined in `pg_opfamily`, `pg_opclass`, `pg_amop`, and `pg_amproc`. These entries allow the planner to determine what kinds of query qualifications can be used with indexes of this access method. Operator families and classes are described in [Section 35.16](#), which is prerequisite material for reading this chapter.

An individual index is defined by a `pg_class` entry that describes it as a physical relation, plus a `pg_index` entry that shows the logical content of the index — that is, the set of index columns it has and the semantics of those columns, as captured by the associated operator classes. The index columns (key values) can be either simple columns of the underlying table or expressions over the table rows. The index access method normally has no interest in where the index key values come from (it is always handed precomputed key values) but it will be very interested in the operator class information in `pg_index`. Both of these catalog entries can be accessed as part of the `Relation` data structure that is passed to all operations on the index.

Some of the flag fields of `IndexAmRoutine` have nonobvious implications. The requirements of `amcanunique` are discussed in [Section 57.5](#). The `amcanmulticol` flag asserts that the access method supports multi-key-column indexes, while `amoptionalkey` asserts that it allows scans where no indexable restriction clause is given for the first index column. When `amcanmulticol` is false, `amoptionalkey` essentially says whether the access method supports full-index scans without any restriction clause. Access methods that support multiple index columns *must* support scans that omit restrictions on any or all of the columns after the first; however they are permitted to require some restriction to appear for the first index column, and this is signaled by setting `amoptionalkey` false. One reason that an index AM might set `amoptionalkey` false is if it doesn't index null values. Since most indexable operators are strict and hence cannot return true for null inputs, it is at first sight attractive to not store index entries for null values: they could never be returned by an index scan anyway. However, this argument fails when an index scan has no restriction clause for a given index column. In practice this means that indexes that have `amoptionalkey` true must index nulls, since the planner might decide to use such an index with no scan keys at all. A related restriction is that an index access method that supports multiple index columns *must* support indexing null values in columns after the first, because the planner will assume the index can be used for queries that do not restrict these columns. For example, consider an index on (a,b) and a query with `WHERE a = 4`. The system will assume the index can be used to scan for rows with `a = 4`, which is wrong if the index omits rows where `b` is null. It is, however, OK to omit rows where the first indexed column is null. An index access method that does index nulls may also set `amsearchnulls`, indicating that it supports `IS NULL` and `IS NOT NULL` clauses as search conditions.

The `amcaninclude` flag indicates whether the access method supports “included” columns, that is it can store (without processing) additional columns beyond the key column(s). The requirements of the preceding paragraph apply only to the key columns. In particular, the combination of `amcanmulticol=false` and `amcaninclude=true` is sensible: it means that there can only be one key column, but there can also be included column(s). Also, included columns must be allowed to be null, independently of `amoptionalkey`.

## 57.2. Index Access Method Functions

The index construction and maintenance functions that an index access method must provide in `IndexAmRoutine` are:

```
IndexBuildResult *
ambuild (Relation heapRelation,
         Relation indexRelation,
         IndexInfo *indexInfo);
```

Build a new index. The index relation has been physically created, but is empty. It must be filled in with whatever fixed data the access method requires, plus entries for all tuples already existing in the table. Ordinarily the `ambuild` function will call `table_index_build_scan()` to scan the table for existing tuples and compute the keys that need to be inserted into the index. The function must return a palloc'd struct containing statistics about the new index.

```
void  
ambuildempty (Relation indexRelation);
```

Build an empty index, and write it to the initialization fork (`INIT_FORKNUM`) of the given relation. This method is called only for unlogged indexes; the empty index written to the initialization fork will be copied over the main relation fork on each server restart.

```
bool  
aminsert (Relation indexRelation,  
          Datum *values,  
          bool *isnull,  
          ItemPointer heap_tid,  
          Relation heapRelation,  
          IndexUniqueCheck checkUnique,  
          IndexInfo *indexInfo);
```

Insert a new tuple into an existing index. The `values` and `isnull` arrays give the key values to be indexed, and `heap_tid` is the TID to be indexed. If the access method supports unique indexes (its `amcanunique` flag is true) then `checkUnique` indicates the type of uniqueness check to perform. This varies depending on whether the unique constraint is deferrable; see [Section 57.5](#) for details. Normally the access method only needs the `heapRelation` parameter when performing uniqueness checking (since then it will have to look into the heap to verify tuple liveness).

The function's Boolean result value is significant only when `checkUnique` is `UNIQUE_CHECK_PARTIAL`. In this case a true result means the new entry is known unique, whereas false means it might be non-unique (and a deferred uniqueness check must be scheduled). For other cases a constant false result is recommended.

Some indexes might not index all tuples. If the tuple is not to be indexed, `aminsert` should just return without doing anything.

If the index AM wishes to cache data across successive index insertions within a SQL statement, it can allocate space in `indexInfo->ii_Context` and store a pointer to the data in `indexInfo->ii_AmCache` (which will be NULL initially).

```
IndexBulkDeleteResult *  
ambulkdelete (IndexVacuumInfo *info,  
             IndexBulkDeleteResult *stats,  
             IndexBulkDeleteCallback callback,  
             void *callback_state);
```

Delete tuple(s) from the index. This is a “bulk delete” operation that is intended to be implemented by scanning the whole index and checking each entry to see if it should be deleted. The passed-in `callback` function must be called, in the style `callback(TID, callback_state)` returns `bool`, to determine whether any particular index entry, as identified by its referenced TID, is to be deleted. Must return either NULL or a palloc'd struct containing statistics about the effects of the deletion operation. It is OK to return NULL if no information needs to be passed on to `amvacuumcleanup`.

Because of limited `maintenance_work_mem`, `ambulkdelete` might need to be called more than once when many tuples are to be deleted. The `stats` argument is the result of the previous call for this index (it is NULL for the first call within a `VACUUM` operation). This allows the AM to accumulate statistics across the whole operation. Typically, `ambulkdelete` will modify and return the same struct if the passed `stats` is not null.

```
IndexBulkDeleteResult *  
amvacuumcleanup (IndexVacuumInfo *info,  
                IndexBulkDeleteResult *stats);
```

Clean up after a `VACUUM` operation (zero or more `ambulkdelete` calls). This does not have to do anything beyond returning index statistics, but it might perform bulk cleanup such as reclaiming empty index pages. `stats` is whatever the last `ambulkdelete` call returned, or NULL if `ambulkdelete` was not called because no tuples needed to be deleted. If the result is not NULL it must be a palloc'd struct. The

statistics it contains will be used to update `pg_class`, and will be reported by `VACUUM` if `VERBOSE` is given. It is OK to return `NULL` if the index was not changed at all during the `VACUUM` operation, but otherwise correct stats should be returned.

As of PostgreSQL 8.4, `amvacuumcleanup` will also be called at completion of an `ANALYZE` operation. In this case `stats` is always `NULL` and any return value will be ignored. This case can be distinguished by checking `info->analyze_only`. It is recommended that the access method do nothing except post-insert cleanup in such a call, and that only in an autovacuum worker process.

```
bool  
amcanreturn (Relation indexRelation, int attno);
```

Check whether the index can support *index-only scans* on the given column, by returning the column's original indexed value. The attribute number is 1-based, i.e., the first column's `attno` is 1. Returns true if supported, else false. This function should always return true for included columns (if those are supported), since there's little point in an included column that can't be retrieved. If the access method does not support index-only scans at all, the `amcanreturn` field in its `IndexAmRoutine` struct can be set to `NULL`.

```
void  
amcostestimate (PlannerInfo *root,  
                IndexPath *path,  
                double loop_count,  
                Cost *indexStartupCost,  
                Cost *indexTotalCost,  
                Selectivity *indexSelectivity,  
                double *indexCorrelation,  
                double *indexPages);
```

Estimate the costs of an index scan. This function is described fully in [Section 57.6](#), below.

```
bytea *  
amoptions (ArrayType *reloptions,  
           bool validate);
```

Parse and validate the `reloptions` array for an index. This is called only when a non-null `reloptions` array exists for the index. `reloptions` is a text array containing entries of the form `name=value`. The function should construct a `bytea` value, which will be copied into the `rd_options` field of the index's `relcache` entry. The data contents of the `bytea` value are open for the access method to define; most of the standard access methods use struct `StdRdOptions`. When `validate` is true, the function should report a suitable error message if any of the options are unrecognized or have invalid values; when `validate` is false, invalid entries should be silently ignored. (`validate` is false when loading options already stored in `pg_catalog`; an invalid entry could only be found if the access method has changed its rules for options, and in that case ignoring obsolete entries is appropriate.) It is OK to return `NULL` if default behavior is wanted.

```
bool  
amproperty (Oid index_oid, int attno,  
            IndexAMProperty prop, const char *propname,  
            bool *res, bool *isnull);
```

The `amproperty` method allows index access methods to override the default behavior of `pg_index_column_has_property` and related functions. If the access method does not have any special behavior for index property inquiries, the `amproperty` field in its `IndexAmRoutine` struct can be set to `NULL`. Otherwise, the `amproperty` method will be called with `index_oid` and `attno` both zero for `pg_indexam_has_property` calls, or with `index_oid` valid and `attno` zero for `pg_index_has_property` calls, or with `index_oid` valid and `attno` greater than zero for `pg_index_column_has_property` calls. `prop` is an enum value identifying the property being tested, while `propname` is the original property name string. If the core code does not recognize the property name then `prop` is `AMPROP_UNKNOWN`. Access methods can define custom property names by checking `propname` for a match (use `pg_strcasecmp` to match, for consistency with the core code); for names known to the core code, it's better to inspect `prop`.

If the `amproperty` method returns `true` then it has determined the property test result: it must set `*res` to the boolean value to return, or set `*isnull` to `true` to return a NULL. (Both of the referenced variables are initialized to `false` before the call.) If the `amproperty` method returns `false` then the core code will proceed with its normal logic for determining the property test result.

Access methods that support ordering operators should implement `AMPROP_DISTANCE_ORDERABLE` property testing, as the core code does not know how to do that and will return NULL. It may also be advantageous to implement `AMPROP_RETURNABLE` testing, if that can be done more cheaply than by opening the index and calling `amcanreturn`, which is the core code's default behavior. The default behavior should be satisfactory for all other standard properties.

```
char *
ambuildphasename (int64 phasenum);
```

Return the textual name of the given build phase number. The phase numbers are those reported during an index build via the `pgstat_progress_update_param` interface. The phase names are then exposed in the `pg_stat_progress_create_index` view.

```
bool
amvalidate (Oid opclassoid);
```

Validate the catalog entries for the specified operator class, so far as the access method can reasonably do that. For example, this might include testing that all required support functions are provided. The `amvalidate` function must return `false` if the opclass is invalid. Problems should be reported with `ereport` messages.

The purpose of an index, of course, is to support scans for tuples matching an indexable `WHERE` condition, often called a *qualifier* or *scan key*. The semantics of index scanning are described more fully in [Section 57.3](#), below. An index access method can support “plain” index scans, “bitmap” index scans, or both. The scan-related functions that an index access method must or may provide are:

```
IndexScanDesc
ambeginscan (Relation indexRelation,
            int nkeys,
            int norderbys);
```

Prepare for an index scan. The `nkeys` and `norderbys` parameters indicate the number of quals and ordering operators that will be used in the scan; these may be useful for space allocation purposes. Note that the actual values of the scan keys aren't provided yet. The result must be a palloc'd struct. For implementation reasons the index access method *must* create this struct by calling `RelationGetIndexScan()`. In most cases `ambeginscan` does little beyond making that call and perhaps acquiring locks; the interesting parts of index-scan startup are in `amrescan`.

```
void
amrescan (IndexScanDesc scan,
         ScanKey keys,
         int nkeys,
         ScanKey orderbys,
         int norderbys);
```

Start or restart an index scan, possibly with new scan keys. (To restart using previously-passed keys, NULL is passed for `keys` and/or `orderbys`.) Note that it is not allowed for the number of keys or order-by operators to be larger than what was passed to `ambeginscan`. In practice the restart feature is used when a new outer tuple is selected by a nested-loop join and so a new key comparison value is needed, but the scan key structure remains the same.

```
bool
amgettupple (IndexScanDesc scan,
            ScanDirection direction);
```

Fetch the next tuple in the given scan, moving in the given direction (forward or backward in the index). Returns `true` if a tuple was obtained, `false` if no matching tuples remain. In the true case the tuple TID

is stored into the `scan` structure. Note that “success” means only that the index contains an entry that matches the scan keys, not that the tuple necessarily still exists in the heap or will pass the caller's snapshot test. On success, `amgettupple` must also set `scan->xs_recheck` to true or false. False means it is certain that the index entry matches the scan keys. True means this is not certain, and the conditions represented by the scan keys must be rechecked against the heap tuple after fetching it. This provision supports “lossy” index operators. Note that rechecking will extend only to the scan conditions; a partial index predicate (if any) is never rechecked by `amgettupple` callers.

If the index supports [index-only scans](#) (i.e., `amcanreturn` returns true for any of its columns), then on success the AM must also check `scan->xs_want_itup`, and if that is true it must return the originally indexed data for the index entry. Columns for which `amcanreturn` returns false can be returned as nulls. The data can be returned in the form of an `IndexTuple` pointer stored at `scan->xs_itup`, with tuple descriptor `scan->xs_itupdesc`; or in the form of a `HeapTuple` pointer stored at `scan->xs_hitup`, with tuple descriptor `scan->xs_hitupdesc`. (The latter format should be used when reconstructing data that might possibly not fit into an `IndexTuple`.) In either case, management of the data referenced by the pointer is the access method's responsibility. The data must remain good at least until the next `amgettupple`, `amrescan`, or `amendscan` call for the scan.

The `amgettupple` function need only be provided if the access method supports “plain” index scans. If it doesn't, the `amgettupple` field in its `IndexAmRoutine` struct must be set to NULL.

```
int64  
amgetbitmap (IndexScanDesc scan,  
            TIDBitmap *tbm);
```

Fetch all tuples in the given scan and add them to the caller-supplied `TIDBitmap` (that is, OR the set of tuple IDs into whatever set is already in the bitmap). The number of tuples fetched is returned (this might be just an approximate count, for instance some AMs do not detect duplicates). While inserting tuple IDs into the bitmap, `amgetbitmap` can indicate that rechecking of the scan conditions is required for specific tuple IDs. This is analogous to the `xs_recheck` output parameter of `amgettupple`. Note: in the current implementation, support for this feature is conflated with support for lossy storage of the bitmap itself, and therefore callers recheck both the scan conditions and the partial index predicate (if any) for recheckable tuples. That might not always be true, however. `amgetbitmap` and `amgettupple` cannot be used in the same index scan; there are other restrictions too when using `amgetbitmap`, as explained in [Section 57.3](#).

The `amgetbitmap` function need only be provided if the access method supports “bitmap” index scans. If it doesn't, the `amgetbitmap` field in its `IndexAmRoutine` struct must be set to NULL.

```
void  
amendscan (IndexScanDesc scan);
```

End a scan and release resources. The `scan` struct itself should not be freed, but any locks or pins taken internally by the access method must be released, as well as any other memory allocated by `ambeginscan` and other scan-related functions.

```
void  
ammarkpos (IndexScanDesc scan);
```

Mark current scan position. The access method need only support one remembered scan position per scan.

The `ammarkpos` function need only be provided if the access method supports ordered scans. If it doesn't, the `ammarkpos` field in its `IndexAmRoutine` struct may be set to NULL.

```
void  
amrestrpos (IndexScanDesc scan);
```

Restore the scan to the most recently marked position.

The `amrestrpos` function need only be provided if the access method supports ordered scans. If it doesn't, the `amrestrpos` field in its `IndexAmRoutine` struct may be set to NULL.

In addition to supporting ordinary index scans, some types of index may wish to support *parallel index scans*, which allow multiple backends to cooperate in performing an index scan. The index access method should arrange things so that each cooperating process returns a subset of the tuples that would be performed by an ordinary, non-parallel index scan, but in such a way that the union of those subsets is equal to the set of tuples that would be returned by an ordinary, non-parallel index scan. Furthermore, while there need not be any global ordering of tuples returned by a parallel scan, the ordering of that subset of tuples returned within each cooperating backend must match the requested ordering. The following functions may be implemented to support parallel index scans:

```
Size  
amestimateparallelscan (void);
```

Estimate and return the number of bytes of dynamic shared memory which the access method will be needed to perform a parallel scan. (This number is in addition to, not in lieu of, the amount of space needed for AM-independent data in `ParallelIndexScanDescData`.)

It is not necessary to implement this function for access methods which do not support parallel scans or for which the number of additional bytes of storage required is zero.

```
void  
aminitparallelscan (void *target);
```

This function will be called to initialize dynamic shared memory at the beginning of a parallel scan. *target* will point to at least the number of bytes previously returned by `amestimateparallelscan`, and this function may use that amount of space to store whatever data it wishes.

It is not necessary to implement this function for access methods which do not support parallel scans or in cases where the shared memory space required needs no initialization.

```
void  
amparallelrescan (IndexScanDesc scan);
```

This function, if implemented, will be called when a parallel index scan must be restarted. It should reset any shared state set up by `aminitparallelscan` such that the scan will be restarted from the beginning.

## 57.3. Index Scanning

In an index scan, the index access method is responsible for regurgitating the TIDs of all the tuples it has been told about that match the *scan keys*. The access method is *not* involved in actually fetching those tuples from the index's parent table, nor in determining whether they pass the scan's visibility test or other conditions.

A scan key is the internal representation of a `WHERE` clause of the form *index\_key operator constant*, where the index key is one of the columns of the index and the operator is one of the members of the operator family associated with that index column. An index scan has zero or more scan keys, which are implicitly ANDed — the returned tuples are expected to satisfy all the indicated conditions.

The access method can report that the index is *lossy*, or requires rechecks, for a particular query. This implies that the index scan will return all the entries that pass the scan key, plus possibly additional entries that do not. The core system's index-scan machinery will then apply the index conditions again to the heap tuple to verify whether or not it really should be selected. If the recheck option is not specified, the index scan must return exactly the set of matching entries.

Note that it is entirely up to the access method to ensure that it correctly finds all and only the entries passing all the given scan keys. Also, the core system will simply hand off all the `WHERE` clauses that match the index keys and operator families, without any semantic analysis to determine whether they are redundant or contradictory. As an example, given `WHERE x > 4 AND x > 14` where *x* is a b-tree indexed column, it is left to the b-tree `amrescan` function to realize that the first scan key is redundant and can be discarded. The extent of preprocessing needed during `amrescan` will depend on the extent to which the index access method needs to reduce the scan keys to a “normalized” form.

Some access methods return index entries in a well-defined order, others do not. There are actually two different ways that an access method can support sorted output:

- Access methods that always return entries in the natural ordering of their data (such as btree) should set `amcanorder` to true. Currently, such access methods must use btree-compatible strategy numbers for their equality and ordering operators.
- Access methods that support ordering operators should set `amcanorderbyop` to true. This indicates that the index is capable of returning entries in an order satisfying `ORDER BY index_key operator constant`. Scan modifiers of that form can be passed to `amrescan` as described previously.

The `amgettuple` function has a `direction` argument, which can be either `ForwardScanDirection` (the normal case) or `BackwardScanDirection`. If the first call after `amrescan` specifies `BackwardScanDirection`, then the set of matching index entries is to be scanned back-to-front rather than in the normal front-to-back direction, so `amgettuple` must return the last matching tuple in the index, rather than the first one as it normally would. (This will only occur for access methods that set `amcanorder` to true.) After the first call, `amgettuple` must be prepared to advance the scan in either direction from the most recently returned entry. (But if `amcanbackward` is false, all subsequent calls will have the same direction as the first one.)

Access methods that support ordered scans must support “marking” a position in a scan and later returning to the marked position. The same position might be restored multiple times. However, only one position need be remembered per scan; a new `ammarkpos` call overrides the previously marked position. An access method that does not support ordered scans need not provide `ammarkpos` and `amrestrpos` functions in `IndexAmRoutine`; set those pointers to NULL instead.

Both the scan position and the mark position (if any) must be maintained consistently in the face of concurrent insertions or deletions in the index. It is OK if a freshly-inserted entry is not returned by a scan that would have found the entry if it had existed when the scan started, or for the scan to return such an entry upon rescanning or backing up even though it had not been returned the first time through. Similarly, a concurrent delete might or might not be reflected in the results of a scan. What is important is that insertions or deletions not cause the scan to miss or multiply return entries that were not themselves being inserted or deleted.

If the index stores the original indexed data values (and not some lossy representation of them), it is useful to support [index-only scans](#), in which the index returns the actual data not just the TID of the heap tuple. This will only avoid I/O if the visibility map shows that the TID is on an all-visible page; else the heap tuple must be visited anyway to check MVCC visibility. But that is no concern of the access method's.

Instead of using `amgettuple`, an index scan can be done with `amgetbitmap` to fetch all tuples in one call. This can be noticeably more efficient than `amgettuple` because it allows avoiding lock/unlock cycles within the access method. In principle `amgetbitmap` should have the same effects as repeated `amgettuple` calls, but we impose several restrictions to simplify matters. First of all, `amgetbitmap` returns all tuples at once and marking or restoring scan positions isn't supported. Secondly, the tuples are returned in a bitmap which doesn't have any specific ordering, which is why `amgetbitmap` doesn't take a `direction` argument. (Ordering operators will never be supplied for such a scan, either.) Also, there is no provision for index-only scans with `amgetbitmap`, since there is no way to return the contents of index tuples. Finally, `amgetbitmap` does not guarantee any locking of the returned tuples, with implications spelled out in [Section 57.4](#).

Note that it is permitted for an access method to implement only `amgetbitmap` and not `amgettuple`, or vice versa, if its internal implementation is unsuited to one API or the other.

## 57.4. Index Locking Considerations

Index access methods must handle concurrent updates of the index by multiple processes. The core Postgres Pro system obtains `AccessShareLock` on the index during an index scan, and `RowExclusiveLock` when updating the index (including plain `VACUUM`). Since these lock types do not conflict, the access

method is responsible for handling any fine-grained locking it might need. An `ACCESS EXCLUSIVE` lock on the index as a whole will be taken only during index creation, destruction, or `REINDEX (SHARE UPDATE EXCLUSIVE)` is taken instead with `CONCURRENTLY`).

Building an index type that supports concurrent updates usually requires extensive and subtle analysis of the required behavior.

Aside from the index's own internal consistency requirements, concurrent updates create issues about consistency between the parent table (the *heap*) and the index. Because Postgres Pro separates accesses and updates of the heap from those of the index, there are windows in which the index might be inconsistent with the heap. We handle this problem with the following rules:

- A new heap entry is made before making its index entries. (Therefore a concurrent index scan is likely to fail to see the heap entry. This is okay because the index reader would be uninterested in an uncommitted row anyway. But see [Section 57.5](#).)
- When a heap entry is to be deleted (by `VACUUM`), all its index entries must be removed first.
- An index scan must maintain a pin on the index page holding the item last returned by `amgettuple`, and `ambulkdelete` cannot delete entries from pages that are pinned by other backends. The need for this rule is explained below.

Without the third rule, it is possible for an index reader to see an index entry just before it is removed by `VACUUM`, and then to arrive at the corresponding heap entry after that was removed by `VACUUM`. This creates no serious problems if that item number is still unused when the reader reaches it, since an empty item slot will be ignored by `heap_fetch()`. But what if a third backend has already re-used the item slot for something else? When using an MVCC-compliant snapshot, there is no problem because the new occupant of the slot is certain to be too new to pass the snapshot test. However, with a non-MVCC-compliant snapshot (such as `SnapshotAny`), it would be possible to accept and return a row that does not in fact match the scan keys. We could defend against this scenario by requiring the scan keys to be rechecked against the heap row in all cases, but that is too expensive. Instead, we use a pin on an index page as a proxy to indicate that the reader might still be “in flight” from the index entry to the matching heap entry. Making `ambulkdelete` block on such a pin ensures that `VACUUM` cannot delete the heap entry before the reader is done with it. This solution costs little in run time, and adds blocking overhead only in the rare cases where there actually is a conflict.

This solution requires that index scans be “synchronous”: we have to fetch each heap tuple immediately after scanning the corresponding index entry. This is expensive for a number of reasons. An “asynchronous” scan in which we collect many TIDs from the index, and only visit the heap tuples sometime later, requires much less index locking overhead and can allow a more efficient heap access pattern. Per the above analysis, we must use the synchronous approach for non-MVCC-compliant snapshots, but an asynchronous scan is workable for a query using an MVCC snapshot.

In an `amgetbitmap` index scan, the access method does not keep an index pin on any of the returned tuples. Therefore it is only safe to use such scans with MVCC-compliant snapshots.

When the `ampredlocks` flag is not set, any scan using that index access method within a serializable transaction will acquire a nonblocking predicate lock on the full index. This will generate a read-write conflict with the insert of any tuple into that index by a concurrent serializable transaction. If certain patterns of read-write conflicts are detected among a set of concurrent serializable transactions, one of those transactions may be canceled to protect data integrity. When the flag is set, it indicates that the index access method implements finer-grained predicate locking, which will tend to reduce the frequency of such transaction cancellations.

## 57.5. Index Uniqueness Checks

Postgres Pro enforces SQL uniqueness constraints using *unique indexes*, which are indexes that disallow multiple entries with identical keys. An access method that supports this feature sets `amcanunique` true. (At present, only b-tree supports it.) Columns listed in the `INCLUDE` clause are not considered when enforcing uniqueness.

Because of MVCC, it is always necessary to allow duplicate entries to exist physically in an index: the entries might refer to successive versions of a single logical row. The behavior we actually want to enforce is that no MVCC snapshot could include two rows with equal index keys. This breaks down into the following cases that must be checked when inserting a new row into a unique index:

- If a conflicting valid row has been deleted by the current transaction, it's okay. (In particular, since an UPDATE always deletes the old row version before inserting the new version, this will allow an UPDATE on a row without changing the key.)
- If a conflicting row has been inserted by an as-yet-uncommitted transaction, the would-be inserter must wait to see if that transaction commits. If it rolls back then there is no conflict. If it commits without deleting the conflicting row again, there is a uniqueness violation. (In practice we just wait for the other transaction to end and then redo the visibility check in toto.)
- Similarly, if a conflicting valid row has been deleted by an as-yet-uncommitted transaction, the would-be inserter must wait for that transaction to commit or abort, and then repeat the test.

Furthermore, immediately before reporting a uniqueness violation according to the above rules, the access method must recheck the liveness of the row being inserted. If it is committed dead then no violation should be reported. (This case cannot occur during the ordinary scenario of inserting a row that's just been created by the current transaction. It can happen during CREATE UNIQUE INDEX CONCURRENTLY, however.)

We require the index access method to apply these tests itself, which means that it must reach into the heap to check the commit status of any row that is shown to have a duplicate key according to the index contents. This is without a doubt ugly and non-modular, but it saves redundant work: if we did a separate probe then the index lookup for a conflicting row would be essentially repeated while finding the place to insert the new row's index entry. What's more, there is no obvious way to avoid race conditions unless the conflict check is an integral part of insertion of the new index entry.

If the unique constraint is deferrable, there is additional complexity: we need to be able to insert an index entry for a new row, but defer any uniqueness-violation error until end of statement or even later. To avoid unnecessary repeat searches of the index, the index access method should do a preliminary uniqueness check during the initial insertion. If this shows that there is definitely no conflicting live tuple, we are done. Otherwise, we schedule a recheck to occur when it is time to enforce the constraint. If, at the time of the recheck, both the inserted tuple and some other tuple with the same key are live, then the error must be reported. (Note that for this purpose, "live" actually means "any tuple in the index entry's HOT chain is live".) To implement this, the `aminert` function is passed a `checkUnique` parameter having one of the following values:

- `UNIQUE_CHECK_NO` indicates that no uniqueness checking should be done (this is not a unique index).
- `UNIQUE_CHECK_YES` indicates that this is a non-deferrable unique index, and the uniqueness check must be done immediately, as described above.
- `UNIQUE_CHECK_PARTIAL` indicates that the unique constraint is deferrable. Postgres Pro will use this mode to insert each row's index entry. The access method must allow duplicate entries into the index, and report any potential duplicates by returning false from `aminert`. For each row for which false is returned, a deferred recheck will be scheduled.

The access method must identify any rows which might violate the unique constraint, but it is not an error for it to report false positives. This allows the check to be done without waiting for other transactions to finish; conflicts reported here are not treated as errors and will be rechecked later, by which time they may no longer be conflicts.

- `UNIQUE_CHECK_EXISTING` indicates that this is a deferred recheck of a row that was reported as a potential uniqueness violation. Although this is implemented by calling `aminert`, the access method must *not* insert a new index entry in this case. The index entry is already present. Rather, the access method must check to see if there is another live index entry. If so, and if the target row is also still live, report error.

It is recommended that in a `UNIQUE_CHECK_EXISTING` call, the access method further verify that the target row actually does have an existing entry in the index, and report error if not. This is a good idea because the index tuple values passed to `aminsert` will have been recomputed. If the index definition involves functions that are not really immutable, we might be checking the wrong area of the index. Checking that the target row is found in the recheck verifies that we are scanning for the same tuple values as were used in the original insertion.

## 57.6. Index Cost Estimation Functions

The `amcostestimate` function is given information describing a possible index scan, including lists of `WHERE` and `ORDER BY` clauses that have been determined to be usable with the index. It must return estimates of the cost of accessing the index and the selectivity of the `WHERE` clauses (that is, the fraction of parent-table rows that will be retrieved during the index scan). For simple cases, nearly all the work of the cost estimator can be done by calling standard routines in the optimizer; the point of having an `amcostestimate` function is to allow index access methods to provide index-type-specific knowledge, in case it is possible to improve on the standard estimates.

Each `amcostestimate` function must have the signature:

```
void  
amcostestimate (PlannerInfo *root,  
                IndexPath *path,  
                double loop_count,  
                Cost *indexStartupCost,  
                Cost *indexTotalCost,  
                Selectivity *indexSelectivity,  
                double *indexCorrelation,  
                double *indexPages);
```

The first three parameters are inputs:

*root*

The planner's information about the query being processed.

*path*

The index access path being considered. All fields except cost and selectivity values are valid.

*loop\_count*

The number of repetitions of the index scan that should be factored into the cost estimates. This will typically be greater than one when considering a parameterized scan for use in the inside of a nestloop join. Note that the cost estimates should still be for just one scan; a larger *loop\_count* means that it may be appropriate to allow for some caching effects across multiple scans.

The last five parameters are pass-by-reference outputs:

*\*indexStartupCost*

Set to cost of index start-up processing

*\*indexTotalCost*

Set to total cost of index processing

*\*indexSelectivity*

Set to index selectivity

*\*indexCorrelation*

Set to correlation coefficient between index scan order and underlying table's order

*\*indexPages*

Set to number of index leaf pages

Note that cost estimate functions must be written in C, not in SQL or any available procedural language, because they must access internal data structures of the planner/optimizer.

The index access costs should be computed using the parameters: a sequential disk block fetch has cost `seq_page_cost`, a nonsequential fetch has cost `random_page_cost`, and the cost of processing one index row should usually be taken as `cpu_index_tuple_cost`. In addition, an appropriate multiple of `cpu_operator_cost` should be charged for any comparison operators invoked during index processing (especially evaluation of the indexquals themselves).

The “start-up cost” is the part of the total scan cost that must be expended before we can begin to fetch the first row. For most indexes this can be taken as zero, but an index type with a high start-up cost might want to set it nonzero.

The *indexSelectivity* should be set to the estimated fraction of the parent table rows that will be retrieved during the index scan. In the case of a lossy query, this will typically be higher than the fraction of rows that actually pass the given qual conditions.

The *indexCorrelation* should be set to the correlation (ranging between -1.0 and 1.0) between the index order and the table order. This is used to adjust the estimate for the cost of fetching rows from the parent table.

The *indexPages* should be set to the number of leaf pages. This is used to estimate the number of workers for parallel index scan.

When *loop\_count* is greater than one, the returned numbers should be averages expected for any one scan of the index.

### Cost Estimation

A typical cost estimator will proceed as follows:

1. Estimate and return the fraction of parent-table rows that will be visited based on the given qual conditions. In the absence of any index-type-specific knowledge, use the standard optimizer function `clauselist_selectivity()`:

```
*indexSelectivity = clauselist_selectivity(root, path->indexquals,
                                           path->indexinfo->rel->reloid,
                                           JOIN_INNER, NULL);
```

2. Estimate the number of index rows that will be visited during the scan. For many index types this is the same as *indexSelectivity* times the number of rows in the index, but it might be more. (Note that the index's size in pages and rows is available from the `path->indexinfo` struct.)
3. Estimate the number of index pages that will be retrieved during the scan. This might be just *indexSelectivity* times the index's size in pages.
4. Compute the index access cost. A generic estimator might do this:

```
/*
 * Our generic assumption is that the index pages will be read
 * sequentially, so they cost seq_page_cost each, not random_page_cost.
 * Also, we charge for evaluation of the indexquals at each index row.
 * All the costs are assumed to be paid incrementally during the scan.
 */
cost_qual_eval(&index_qual_cost, path->indexquals, root);
*indexStartupCost = index_qual_cost.startup;
*indexTotalCost = seq_page_cost * numIndexPages +
                 (cpu_index_tuple_cost + index_qual_cost.per_tuple) * numIndexTuples;
```

However, the above does not account for amortization of index reads across repeated index scans.

5. Estimate the index correlation. For a simple ordered index on a single field, this can be retrieved from `pg_statistic`. If the correlation is not known, the conservative estimate is zero (no correlation).

---

## Chapter 58. Generic WAL Records

Although all built-in WAL-logged modules have their own types of WAL records, there is also a generic WAL record type, which describes changes to pages in a generic way. This is useful for extensions that provide custom access methods, because they cannot register their own WAL redo routines.

The API for constructing generic WAL records is defined in `access/generic_xlog.h` and implemented in `access/transam/generic_xlog.c`.

To perform a WAL-logged data update using the generic WAL record facility, follow these steps:

1. `state = GenericXLogStart(relation)` — start construction of a generic WAL record for the given relation.
2. `page = GenericXLogRegisterBuffer(state, buffer, flags)` — register a buffer to be modified within the current generic WAL record. This function returns a pointer to a temporary copy of the buffer's page, where modifications should be made. (Do not modify the buffer's contents directly.) The third argument is a bit mask of flags applicable to the operation. Currently the only such flag is `GENERIC_XLOG_FULL_IMAGE`, which indicates that a full-page image rather than a delta update should be included in the WAL record. Typically this flag would be set if the page is new or has been rewritten completely. `GenericXLogRegisterBuffer` can be repeated if the WAL-logged action needs to modify multiple pages.
3. Apply modifications to the page images obtained in the previous step.
4. `GenericXLogFinish(state)` — apply the changes to the buffers and emit the generic WAL record.

WAL record construction can be canceled between any of the above steps by calling `GenericXLogAbort(state)`. This will discard all changes to the page image copies.

Please note the following points when using the generic WAL record facility:

- No direct modifications of buffers are allowed! All modifications must be done in copies acquired from `GenericXLogRegisterBuffer()`. In other words, code that makes generic WAL records should never call `BufferGetPage()` for itself. However, it remains the caller's responsibility to pin/unpin and lock/unlock the buffers at appropriate times. Exclusive lock must be held on each target buffer from before `GenericXLogRegisterBuffer()` until after `GenericXLogFinish()`.
- Registrations of buffers (step 2) and modifications of page images (step 3) can be mixed freely, i.e., both steps may be repeated in any sequence. Keep in mind that buffers should be registered in the same order in which locks are to be obtained on them during replay.
- The maximum number of buffers that can be registered for a generic WAL record is `MAX_GENERIC_XLOG_PAGES`. An error will be thrown if this limit is exceeded.
- Generic WAL assumes that the pages to be modified have standard layout, and in particular that there is no useful data between `pd_lower` and `pd_upper`.
- Since you are modifying copies of buffer pages, `GenericXLogStart()` does not start a critical section. Thus, you can safely do memory allocation, error throwing, etc. between `GenericXLogStart()` and `GenericXLogFinish()`. The only actual critical section is present inside `GenericXLogFinish()`. There is no need to worry about calling `GenericXLogAbort()` during an error exit, either.
- `GenericXLogFinish()` takes care of marking buffers dirty and setting their LSNs. You do not need to do this explicitly.
- For unlogged relations, everything works the same except that no actual WAL record is emitted. Thus, you typically do not need to do any explicit checks for unlogged relations.
- The generic WAL redo function will acquire exclusive locks to buffers in the same order as they were registered. After redoing all changes, the locks will be released in the same order.
- If `GENERIC_XLOG_FULL_IMAGE` is not specified for a registered buffer, the generic WAL record contains a delta between the old and the new page images. This delta is based on byte-by-byte

comparison. This is not very compact for the case of moving data within a page, and might be improved in the future.

---

# Chapter 59. B-Tree Indexes

## 59.1. Introduction

Postgres Pro includes an implementation of the standard btree (multi-way balanced tree) index data structure. Any data type that can be sorted into a well-defined linear order can be indexed by a btree index. The only limitation is that an index entry cannot exceed approximately one-third of a page (after TOAST compression, if applicable).

Because each btree operator class imposes a sort order on its data type, btree operator classes (or, really, operator families) have come to be used as Postgres Pro's general representation and understanding of sorting semantics. Therefore, they've acquired some features that go beyond what would be needed just to support btree indexes, and parts of the system that are quite distant from the btree AM make use of them.

## 59.2. Behavior of B-Tree Operator Classes

As shown in [Table 35.3](#), a btree operator class must provide five comparison operators, `<`, `<=`, `=`, `>=` and `>`. One might expect that `<>` should also be part of the operator class, but it is not, because it would almost never be useful to use a `<>` WHERE clause in an index search. (For some purposes, the planner treats `<>` as associated with a btree operator class; but it finds that operator via the `=` operator's negator link, rather than from `pg_amop`.)

When several data types share near-identical sorting semantics, their operator classes can be grouped into an operator family. Doing so is advantageous because it allows the planner to make deductions about cross-type comparisons. Each operator class within the family should contain the single-type operators (and associated support functions) for its input data type, while cross-type comparison operators and support functions are “loose” in the family. It is recommendable that a complete set of cross-type operators be included in the family, thus ensuring that the planner can represent any comparison conditions that it deduces from transitivity.

There are some basic assumptions that a btree operator family must satisfy:

- An `=` operator must be an equivalence relation; that is, for all non-null values  $A$ ,  $B$ ,  $C$  of the data type:
  - $A = A$  is true (*reflexive law*)
  - if  $A = B$ , then  $B = A$  (*symmetric law*)
  - if  $A = B$  and  $B = C$ , then  $A = C$  (*transitive law*)
- A `<` operator must be a strong ordering relation; that is, for all non-null values  $A$ ,  $B$ ,  $C$ :
  - $A < A$  is false (*irreflexive law*)
  - if  $A < B$  and  $B < C$ , then  $A < C$  (*transitive law*)
- Furthermore, the ordering is total; that is, for all non-null values  $A$ ,  $B$ :
  - exactly one of  $A < B$ ,  $A = B$ , and  $B < A$  is true (*trichotomy law*)

(The trichotomy law justifies the definition of the comparison support function, of course.)

The other three operators are defined in terms of `=` and `<` in the obvious way, and must act consistently with them.

For an operator family supporting multiple data types, the above laws must hold when  $A$ ,  $B$ ,  $C$  are taken from any data types in the family. The transitive laws are the trickiest to ensure, as in cross-type situations they represent statements that the behaviors of two or three different operators are consistent. As an example, it would not work to put `float8` and `numeric` into the same operator family, at least not with the current semantics that `numeric` values are converted to `float8` for comparison to a `float8`. Because

of the limited accuracy of `float8`, this means there are distinct `numeric` values that will compare equal to the same `float8` value, and thus the transitive law would fail.

Another requirement for a multiple-data-type family is that any implicit or binary-coercion casts that are defined between data types included in the operator family must not change the associated sort ordering.

It should be fairly clear why a `btree` index requires these laws to hold within a single data type: without them there is no ordering to arrange the keys with. Also, index searches using a comparison key of a different data type require comparisons to behave sanely across two data types. The extensions to three or more data types within a family are not strictly required by the `btree` index mechanism itself, but the planner relies on them for optimization purposes.

## 59.3. B-Tree Support Functions

As shown in [Table 35.9](#), `btree` defines one required and four optional support functions. The five user-defined methods are:

`order`

For each combination of data types that a `btree` operator family provides comparison operators for, it must provide a comparison support function, registered in `pg_amproc` with support function number 1 and `amproclefttype/amprocrighttype` equal to the left and right data types for the comparison (i.e., the same data types that the matching operators are registered with in `pg_amop`). The comparison function must take two non-null values *A* and *B* and return an `int32` value that is `< 0`, `0`, or `> 0` when  $A < B$ ,  $A = B$ , or  $A > B$ , respectively. A null result is disallowed: all values of the data type must be comparable.

If the compared values are of a collatable data type, the appropriate collation OID will be passed to the comparison support function, using the standard `PG_GET_COLLATION()` mechanism.

`sortsupport`

Optionally, a `btree` operator family may provide *sort support* function(s), registered under support function number 2. These functions allow implementing comparisons for sorting purposes in a more efficient way than naively calling the comparison support function. The APIs involved in this are defined in `src/include/utils/sortsupport.h`.

`in_range`

Optionally, a `btree` operator family may provide *in\_range* support function(s), registered under support function number 3. These are not used during `btree` index operations; rather, they extend the semantics of the operator family so that it can support window clauses containing the `RANGE offset PRECEDING` and `RANGE offset FOLLOWING` frame bound types (see [Section 4.2.8](#)). Fundamentally, the extra information provided is how to add or subtract an *offset* value in a way that is compatible with the family's data ordering.

An `in_range` function must have the signature

```
in_range(val type1, base type1, offset type2, sub bool, less bool)
returns bool
```

*val* and *base* must be of the same type, which is one of the types supported by the operator family (i.e., a type for which it provides an ordering). However, *offset* could be of a different type, which might be one otherwise unsupported by the family. An example is that the built-in `time_ops` family provides an `in_range` function that has *offset* of type `interval`. A family can provide `in_range` functions for any of its supported types and one or more *offset* types. Each `in_range` function should be entered in `pg_amproc` with `amproclefttype` equal to `type1` and `amprocrighttype` equal to `type2`.

The essential semantics of an `in_range` function depend on the two Boolean flag parameters. It should add or subtract *base* and *offset*, then compare *val* to the result, as follows:

- if `!sub` and `!less`, return `val >= (base + offset)`

- if *!sub* and *less*, return  $val \leq (base + offset)$
- if *sub* and *!less*, return  $val \geq (base - offset)$
- if *sub* and *less*, return  $val \leq (base - offset)$

Before doing so, the function should check the sign of *offset*: if it is less than zero, raise error `ERRCODE_INVALID_PRECEDING_OR_FOLLOWING_SIZE (22013)` with error text like “invalid preceding or following size in window function”. (This is required by the SQL standard, although nonstandard operator families might perhaps choose to ignore this restriction, since there seems to be little semantic necessity for it.) This requirement is delegated to the `in_range` function so that the core code needn't understand what “less than zero” means for a particular data type.

An additional expectation is that `in_range` functions should, if practical, avoid throwing an error if  $base + offset$  or  $base - offset$  would overflow. The correct comparison result can be determined even if that value would be out of the data type's range. Note that if the data type includes concepts such as “infinity” or “NaN”, extra care may be needed to ensure that `in_range`'s results agree with the normal sort order of the operator family.

The results of the `in_range` function must be consistent with the sort ordering imposed by the operator family. To be precise, given any fixed values of *offset* and *sub*, then:

- If `in_range` with *less* = true is true for some *val1* and *base*, it must be true for every  $val2 \leq val1$  with the same *base*.
- If `in_range` with *less* = true is false for some *val1* and *base*, it must be false for every  $val2 \geq val1$  with the same *base*.
- If `in_range` with *less* = true is true for some *val* and *base1*, it must be true for every  $base2 \geq base1$  with the same *val*.
- If `in_range` with *less* = true is false for some *val* and *base1*, it must be false for every  $base2 \leq base1$  with the same *val*.

Analogous statements with inverted conditions hold when *less* = false.

If the type being ordered (*type1*) is collatable, the appropriate collation OID will be passed to the `in_range` function, using the standard `PG_GET_COLLATION()` mechanism.

`in_range` functions need not handle NULL inputs, and typically will be marked strict.

#### equalimage

Optionally, a btree operator family may provide `equalimage` (“equality implies image equality”) support functions, registered under support function number 4. These functions allow the core code to determine when it is safe to apply the btree deduplication optimization. Currently, `equalimage` functions are only called when building or rebuilding an index.

An `equalimage` function must have the signature

```
equalimage(opcintype oid) returns bool
```

The return value is static information about an operator class and collation. Returning `true` indicates that the `order` function for the operator class is guaranteed to only return 0 (“arguments are equal”) when its *A* and *B* arguments are also interchangeable without any loss of semantic information. Not registering an `equalimage` function or returning `false` indicates that this condition cannot be assumed to hold.

The *opcintype* argument is the `pg_type.oid` of the data type that the operator class indexes. This is a convenience that allows reuse of the same underlying `equalimage` function across operator classes. If *opcintype* is a collatable data type, the appropriate collation OID will be passed to the `equalimage` function, using the standard `PG_GET_COLLATION()` mechanism.

As far as the operator class is concerned, returning `true` indicates that deduplication is safe (or safe for the collation whose OID was passed to its `equalimage` function). However, the core code will

only deem deduplication safe for an index when *every* indexed column uses an operator class that registers an `equalimage` function, and each function actually returns `true` when called.

Image equality is *almost* the same condition as simple bitwise equality. There is one subtle difference: When indexing a varlena data type, the on-disk representation of two image equal datums may not be bitwise equal due to inconsistent application of TOAST compression on input. Formally, when an operator class's `equalimage` function returns `true`, it is safe to assume that the `datum_image_eq()` C function will always agree with the operator class's `order` function (provided that the same collation OID is passed to both the `equalimage` and `order` functions).

The core code is fundamentally unable to deduce anything about the “equality implies image equality” status of an operator class within a multiple-data-type family based on details from other operator classes in the same family. Also, it is not sensible for an operator family to register a cross-type `equalimage` function, and attempting to do so will result in an error. This is because “equality implies image equality” status does not just depend on sorting/equality semantics, which are more or less defined at the operator family level. In general, the semantics that one particular data type implements must be considered separately.

The convention followed by the operator classes included with the core PostgreSQL distribution is to register a stock, generic `equalimage` function. Most operator classes register `btequalimage()`, which indicates that deduplication is safe unconditionally. Operator classes for collatable data types such as text register `btvarstrequalimage()`, which indicates that deduplication is safe with deterministic collations. Best practice for third-party extensions is to register their own custom function to retain control.

`options`

Optionally, a B-tree operator family may provide `options` (“operator class specific options”) support functions, registered under support function number 5. These functions define a set of user-visible parameters that control operator class behavior.

An `options` support function must have the signature

```
options(relopts local_relopts *) returns void
```

The function is passed a pointer to a `local_relopts` struct, which needs to be filled with a set of operator class specific options. The options can be accessed from other support functions using the `PG_HAS_OPCLASS_OPTIONS()` and `PG_GET_OPCLASS_OPTIONS()` macros.

Currently, no B-Tree operator class has an `options` support function. B-tree doesn't allow flexible representation of keys like GiST, SP-GiST, GIN and BRIN do. So, `options` probably doesn't have much application in the current B-tree index access method. Nevertheless, this support function was added to B-tree for uniformity, and will probably find uses during further evolution of B-tree in PostgreSQL.

## 59.4. Implementation

This section covers B-Tree index implementation details that may be of use to advanced users.

### 59.4.1. B-Tree Structure

PostgreSQL B-Tree indexes are multi-level tree structures, where each level of the tree can be used as a doubly-linked list of pages. A single metapage is stored in a fixed position at the start of the first segment file of the index. All other pages are either leaf pages or internal pages. Leaf pages are the pages on the lowest level of the tree. All other levels consist of internal pages. Each leaf page contains tuples that point to table rows. Each internal page contains tuples that point to the next level down in the tree. Typically, over 99% of all pages are leaf pages. Both internal pages and leaf pages use the standard page format described in [Section 65.6](#).

New leaf pages are added to a B-Tree index when an existing leaf page cannot fit an incoming tuple. A *page split* operation makes room for items that originally belonged on the overflowing page by moving a portion of the items to a new page. Page splits must also insert a new *downlink* to the new page in the

parent page, which may cause the parent to split in turn. Page splits “cascade upwards” in a recursive fashion. When the root page finally cannot fit a new downlink, a *root page split* operation takes place. This adds a new level to the tree structure by creating a new root page that is one level above the original root page.

## 59.4.2. Deduplication

A duplicate is a leaf page tuple (a tuple that points to a table row) where *all* indexed key columns have values that match corresponding column values from at least one other leaf page tuple in the same index. Duplicate tuples are quite common in practice. B-Tree indexes can use a special, space-efficient representation for duplicates when an optional technique is enabled: *deduplication*.

Deduplication works by periodically merging groups of duplicate tuples together, forming a single *posting list* tuple for each group. The column key value(s) only appear once in this representation. This is followed by a sorted array of TIDs that point to rows in the table. This significantly reduces the storage size of indexes where each value (or each distinct combination of column values) appears several times on average. The latency of queries can be reduced significantly. Overall query throughput may increase significantly. The overhead of routine index vacuuming may also be reduced significantly.

### Note

B-Tree deduplication is just as effective with “duplicates” that contain a NULL value, even though NULL values are never equal to each other according to the = member of any B-Tree operator class. As far as any part of the implementation that understands the on-disk B-Tree structure is concerned, NULL is just another value from the domain of indexed values.

The deduplication process occurs lazily, when a new item is inserted that cannot fit on an existing leaf page. This prevents (or at least delays) leaf page splits. Unlike GIN posting list tuples, B-Tree posting list tuples do not need to expand every time a new duplicate is inserted; they are merely an alternative physical representation of the original logical contents of the leaf page. This design prioritizes consistent performance with mixed read-write workloads. Most client applications will at least see a moderate performance benefit from using deduplication. Deduplication is enabled by default.

`CREATE INDEX` and `REINDEX` apply deduplication to create posting list tuples, though the strategy they use is slightly different. Each group of duplicate ordinary tuples encountered in the sorted input taken from the table is merged into a posting list tuple *before* being added to the current pending leaf page. Individual posting list tuples are packed with as many TIDs as possible. Leaf pages are written out in the usual way, without any separate deduplication pass. This strategy is well-suited to `CREATE INDEX` and `REINDEX` because they are once-off batch operations.

Write-heavy workloads that don't benefit from deduplication due to having few or no duplicate values in indexes will incur a small, fixed performance penalty (unless deduplication is explicitly disabled). The `deduplicate_items` storage parameter can be used to disable deduplication within individual indexes. There is never any performance penalty with read-only workloads, since reading posting list tuples is at least as efficient as reading the standard tuple representation. Disabling deduplication isn't usually helpful.

B-Tree indexes are not directly aware that under MVCC, there might be multiple extant versions of the same logical table row; to an index, each tuple is an independent object that needs its own index entry. “Version duplicates” may sometimes accumulate and adversely affect query latency and throughput. This typically occurs with `UPDATE`-heavy workloads where most individual updates cannot apply the HOT optimization (often because at least one indexed column gets modified, necessitating a new set of index tuple versions — one new tuple for *each and every* index). In effect, B-Tree deduplication ameliorates index bloat caused by version churn. Note that even the tuples from a unique index are not necessarily *physically* unique when stored on disk due to version churn. The deduplication optimization is selectively applied within unique indexes. It targets those pages that appear to have version duplicates. The high level goal is to give `VACUUM` more time to run before an “unnecessary” page split caused by version churn can take place.

### Tip

A special heuristic is applied to determine whether a deduplication pass in a unique index should take place. It can often skip straight to splitting a leaf page, avoiding a performance penalty from wasting cycles on unhelpful deduplication passes. If you're concerned about the overhead of deduplication, consider setting `deduplicate_items = off` selectively. Leaving deduplication enabled in unique indexes has little downside.

Deduplication cannot be used in all cases due to implementation-level restrictions. Deduplication safety is determined when `CREATE INDEX` or `REINDEX` is run.

Note that deduplication is deemed unsafe and cannot be used in the following cases involving semantically significant differences among equal datums:

- `text`, `varchar`, and `char` cannot use deduplication when a *nondeterministic* collation is used. Case and accent differences must be preserved among equal datums.
- `numeric` cannot use deduplication. Numeric display scale must be preserved among equal datums.
- `jsonb` cannot use deduplication, since the `jsonb` B-Tree operator class uses `numeric` internally.
- `float4` and `float8` cannot use deduplication. These types have distinct representations for `-0` and `0`, which are nevertheless considered equal. This difference must be preserved.

There is one further implementation-level restriction that may be lifted in a future version of PostgreSQL:

- Container types (such as composite types, arrays, or range types) cannot use deduplication.

There is one further implementation-level restriction that applies regardless of the operator class or collation used:

- `INCLUDE` indexes can never use deduplication.

---

# Chapter 60. GiST Indexes

## 60.1. Introduction

GiST stands for Generalized Search Tree. It is a balanced, tree-structured access method, that acts as a base template in which to implement arbitrary indexing schemes. B-trees, R-trees and many other indexing schemes can be implemented in GiST.

One advantage of GiST is that it allows the development of custom data types with the appropriate access methods, by an expert in the domain of the data type, rather than a database expert.

Some of the information here is derived from the University of California at Berkeley's GiST Indexing Project [web site](#) and Marcel Kornacker's thesis, [Access Methods for Next-Generation Database Systems](#). The GiST implementation in Postgres Pro is primarily maintained by Teodor Sigaev and Oleg Bartunov, and there is more information on their [web site](#).

## 60.2. Built-in Operator Classes

The core Postgres Pro distribution includes the GiST operator classes shown in [Table 60.1](#). (Some of the optional modules described in [Appendix F](#) provide additional GiST operator classes.)

**Table 60.1. Built-in GiST Operator Classes**

Name	Indexed Data Type	Indexable Operators	Ordering Operators
box_ops	box	&& &> &< &<  >> << <<  <@ @> @  &>  >> ~ ~=	<->
circle_ops	circle	&& &> &< &<  >> << <<  <@ @> @  &>  >> ~ ~=	<->
inet_ops	inet, cidr	&& >> >>= > >= <> << <<= < <= =	
point_ops	point	>> >^ << <@ <@ <@ <^ ~= <@ @>	<->
poly_ops	polygon	&& &> &< &<  >> << <<  <@ @> @  &>  >> ~ ~=	<->
range_ops	any range type	&& &> &< >> << <@ -  - = @> @>	
tsquery_ops	tsquery	<@ @>	
tsvector_ops	tsvector	@@	

For historical reasons, the `inet_ops` operator class is not the default class for types `inet` and `cidr`. To use it, mention the class name in `CREATE INDEX`, for example

```
CREATE INDEX ON my_table USING GIST (my_inet_column inet_ops);
```

## 60.3. Extensibility

Traditionally, implementing a new index access method meant a lot of difficult work. It was necessary to understand the inner workings of the database, such as the lock manager and Write-Ahead Log. The GiST interface has a high level of abstraction, requiring the access method implementer only to implement the semantics of the data type being accessed. The GiST layer itself takes care of concurrency, logging and searching the tree structure.

This extensibility should not be confused with the extensibility of the other standard search trees in terms of the data they can handle. For example, Postgres Pro supports extensible B-trees and hash indexes. That means that you can use Postgres Pro to build a B-tree or hash over any data type you want. But B-trees only support range predicates (`<`, `=`, `>`), and hash indexes only support equality queries.

So if you index, say, an image collection with a Postgres Pro B-tree, you can only issue queries such as “is imagex equal to imagey”, “is imagex less than imagey” and “is imagex greater than imagey”. Depending on how you define “equals”, “less than” and “greater than” in this context, this could be useful. However, by using a GiST based index, you could create ways to ask domain-specific questions, perhaps “find all images of horses” or “find all over-exposed images”.

All it takes to get a GiST access method up and running is to implement several user-defined methods, which define the behavior of keys in the tree. Of course these methods have to be pretty fancy to support fancy queries, but for all the standard queries (B-trees, R-trees, etc.) they're relatively straightforward. In short, GiST combines extensibility along with generality, code reuse, and a clean interface.

There are five methods that an index operator class for GiST must provide, and five that are optional. Correctness of the index is ensured by proper implementation of the `same`, `consistent` and `union` methods, while efficiency (size and speed) of the index will depend on the `penalty` and `picksplit` methods. Two optional methods are `compress` and `decompress`, which allow an index to have internal tree data of a different type than the data it indexes. The leaves are to be of the indexed data type, while the other tree nodes can be of any C struct (but you still have to follow Postgres Pro data type rules here, see about `varlena` for variable sized data). If the tree's internal data type exists at the SQL level, the `STORAGE` option of the `CREATE OPERATOR CLASS` command can be used. The optional eighth method is `distance`, which is needed if the operator class wishes to support ordered scans (nearest-neighbor searches). The optional ninth method `fetch` is needed if the operator class wishes to support index-only scans, except when the `compress` method is omitted. The optional tenth method `options` is needed if the operator class provides the user-specified parameters.

`consistent`

Given an index entry `p` and a query value `q`, this function determines whether the index entry is “consistent” with the query; that is, could the predicate “`indexed_column indexable_operator q`” be true for any row represented by the index entry? For a leaf index entry this is equivalent to testing the indexable condition, while for an internal tree node this determines whether it is necessary to scan the subtree of the index represented by the tree node. When the result is `true`, a `recheck` flag must also be returned. This indicates whether the predicate is certainly true or only possibly true. If `recheck = false` then the index has tested the predicate condition exactly, whereas if `recheck = true` the row is only a candidate match. In that case the system will automatically evaluate the `indexable_operator` against the actual row value to see if it is really a match. This convention allows GiST to support both lossless and lossy index structures.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_consistent(internal, data_type, smallint, oid,
    internal)
RETURNS bool
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_consistent);

Datum
my_consistent(PG_FUNCTION_ARGS)
{
    GISTENTRY *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
    data_type *query = PG_GETARG_DATA_TYPE_P(1);
    StrategyNumber strategy = (StrategyNumber) PG_GETARG_UINT16(2);
    /* Oid subtype = PG_GETARG_OID(3); */
    bool *recheck = (bool *) PG_GETARG_POINTER(4);
    data_type *key = DatumGetDataTypes(entry->key);
    bool retval;

    /*
```

```

    * determine return value as a function of strategy, key and query.
    *
    * Use GIST_LEAF(entry) to know where you're called in the index tree,
    * which comes handy when supporting the = operator for example (you could
    * check for non empty union() in non-leaf nodes and equality in leaf
    * nodes).
    */

    *recheck = true;          /* or false if check is exact */

    PG_RETURN_BOOL(retval);
}

```

Here, `key` is an element in the index and `query` the value being looked up in the index. The `StrategyNumber` parameter indicates which operator of your operator class is being applied — it matches one of the operator numbers in the `CREATE OPERATOR CLASS` command.

Depending on which operators you have included in the class, the data type of `query` could vary with the operator, since it will be whatever type is on the righthand side of the operator, which might be different from the indexed data type appearing on the lefthand side. (The above code skeleton assumes that only one type is possible; if not, fetching the `query` argument value would have to depend on the operator.) It is recommended that the SQL declaration of the `consistent` function use the `opclass`'s indexed data type for the `query` argument, even though the actual type might be something else depending on the operator.

`union`

This method consolidates information in the tree. Given a set of entries, this function generates a new index entry that represents all the given entries.

The SQL declaration of the function must look like this:

```

CREATE OR REPLACE FUNCTION my_union(internal, internal)
RETURNS storage_type
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;

```

And the matching code in the C module could then follow this skeleton:

```

PG_FUNCTION_INFO_V1(my_union);

Datum
my_union(PG_FUNCTION_ARGS)
{
    GistEntryVector *entryvec = (GistEntryVector *) PG_GETARG_POINTER(0);
    GISTENTRY *ent = entryvec->vector;
    data_type *out,
              *tmp,
              *old;
    int numranges,
        i = 0;

    numranges = entryvec->n;
    tmp = DatumGetDataTypes(ent[0].key);
    out = tmp;

    if (numranges == 1)
    {
        out = data_type_deep_copy(tmp);

        PG_RETURN_DATA_TYPE_P(out);
    }
}

```

```

for (i = 1; i < numranges; i++)
{
    old = out;
    tmp = DatumGetDataType(ent[i].key);
    out = my_union_implementation(out, tmp);
}

PG_RETURN_DATA_TYPE_P(out);
}

```

As you can see, in this skeleton we're dealing with a data type where `union(X, Y, Z) = union(union(X, Y), Z)`. It's easy enough to support data types where this is not the case, by implementing the proper union algorithm in this GiST support method.

The result of the `union` function must be a value of the index's storage type, whatever that is (it might or might not be different from the indexed column's type). The `union` function should return a pointer to newly `palloc()`ed memory. You can't just return the input value as-is, even if there is no type change.

As shown above, the `union` function's first internal argument is actually a `GistEntryVector` pointer. The second argument is a pointer to an integer variable, which can be ignored. (It used to be required that the `union` function store the size of its result value into that variable, but this is no longer necessary.)

`compress`

Converts a data item into a format suitable for physical storage in an index page. If the `compress` method is omitted, data items are stored in the index without modification.

The SQL declaration of the function must look like this:

```

CREATE OR REPLACE FUNCTION my_compress(internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;

```

And the matching code in the C module could then follow this skeleton:

```

PG_FUNCTION_INFO_V1(my_compress);

Datum
my_compress(PG_FUNCTION_ARGS)
{
    GISTENTRY *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
    GISTENTRY *retval;

    if (entry->leafkey)
    {
        /* replace entry->key with a compressed version */
        compressed_data_type *compressed_data =
palloc(sizeof(compressed_data_type));

        /* fill *compressed_data from entry->key ... */

        retval = palloc(sizeof(GISTENTRY));
        gistentryinit(*retval, PointerGetDatum(compressed_data),
                    entry->rel, entry->page, entry->offset, FALSE);
    }
    else
    {
        /* typically we needn't do anything with non-leaf entries */

```

```

        retval = entry;
    }

    PG_RETURN_POINTER(retval);
}

```

You have to adapt *compressed\_data\_type* to the specific type you're converting to in order to compress your leaf nodes, of course.

#### decompress

Converts the stored representation of a data item into a format that can be manipulated by the other GiST methods in the operator class. If the *decompress* method is omitted, it is assumed that the other GiST methods can work directly on the stored data format. (*decompress* is not necessarily the reverse of the *compress* method; in particular, if *compress* is lossy then it's impossible for *decompress* to exactly reconstruct the original data. *decompress* is not necessarily equivalent to *fetch*, either, since the other GiST methods might not require full reconstruction of the data.)

The SQL declaration of the function must look like this:

```

CREATE OR REPLACE FUNCTION my_decompress(internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;

```

And the matching code in the C module could then follow this skeleton:

```

PG_FUNCTION_INFO_V1(my_decompress);

Datum
my_decompress(PG_FUNCTION_ARGS)
{
    PG_RETURN_POINTER(PG_GETARG_POINTER(0));
}

```

The above skeleton is suitable for the case where no decompression is needed. (But, of course, omitting the method altogether is even easier, and is recommended in such cases.)

#### penalty

Returns a value indicating the “cost” of inserting the new entry into a particular branch of the tree. Items will be inserted down the path of least *penalty* in the tree. Values returned by *penalty* should be non-negative. If a negative value is returned, it will be treated as zero.

The SQL declaration of the function must look like this:

```

CREATE OR REPLACE FUNCTION my_penalty(internal, internal, internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT; -- in some cases penalty functions need not be strict

```

And the matching code in the C module could then follow this skeleton:

```

PG_FUNCTION_INFO_V1(my_penalty);

Datum
my_penalty(PG_FUNCTION_ARGS)
{
    GISTENTRY *origentry = (GISTENTRY *) PG_GETARG_POINTER(0);
    GISTENTRY *newentry = (GISTENTRY *) PG_GETARG_POINTER(1);
    float *penalty = (float *) PG_GETARG_POINTER(2);
    data_type *orig = DatumGetDataTypes(origentry->key);
    data_type *new = DatumGetDataTypes(newentry->key);

    *penalty = my_penalty_implementation(orig, new);
}

```

```

    PG_RETURN_POINTER(penalty);
}

```

For historical reasons, the `penalty` function doesn't just return a `float` result; instead it has to store the value at the location indicated by the third argument. The return value per se is ignored, though it's conventional to pass back the address of that argument.

The `penalty` function is crucial to good performance of the index. It'll get used at insertion time to determine which branch to follow when choosing where to add the new entry in the tree. At query time, the more balanced the index, the quicker the lookup.

#### `picksplit`

When an index page split is necessary, this function decides which entries on the page are to stay on the old page, and which are to move to the new page.

The SQL declaration of the function must look like this:

```

CREATE OR REPLACE FUNCTION my_picksplit(internal, internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;

```

And the matching code in the C module could then follow this skeleton:

```

PG_FUNCTION_INFO_V1(my_picksplit);

Datum
my_picksplit(PG_FUNCTION_ARGS)
{
    GistEntryVector *entryvec = (GistEntryVector *) PG_GETARG_POINTER(0);
    GIST_SPLITVEC *v = (GIST_SPLITVEC *) PG_GETARG_POINTER(1);
    OffsetNumber maxoff = entryvec->n - 1;
    GISTENTRY *ent = entryvec->vector;
    int i,
        nbytes;
    OffsetNumber *left,
        *right;
    data_type *tmp_union;
    data_type *unionL;
    data_type *unionR;
    GISTENTRY **raw_entryvec;

    maxoff = entryvec->n - 1;
    nbytes = (maxoff + 1) * sizeof(OffsetNumber);

    v->spl_left = (OffsetNumber *) palloc(nbytes);
    left = v->spl_left;
    v->spl_nleft = 0;

    v->spl_right = (OffsetNumber *) palloc(nbytes);
    right = v->spl_right;
    v->spl_nright = 0;

    unionL = NULL;
    unionR = NULL;

    /* Initialize the raw entry vector. */
    raw_entryvec = (GISTENTRY **) malloc(entryvec->n * sizeof(void *));
    for (i = FirstOffsetNumber; i <= maxoff; i = OffsetNumberNext(i))
        raw_entryvec[i] = &(entryvec->vector[i]);
}

```

```

for (i = FirstOffsetNumber; i <= maxoff; i = OffsetNumberNext(i))
{
    int            real_index = raw_entryvec[i] - entryvec->vector;

    tmp_union = DatumGetDataType(entryvec->vector[real_index].key);
    Assert(tmp_union != NULL);

    /*
     * Choose where to put the index entries and update unionL and unionR
     * accordingly. Append the entries to either v->spl_left or
     * v->spl_right, and care about the counters.
     */

    if (my_choice_is_left(unionL, curl, unionR, curr))
    {
        if (unionL == NULL)
            unionL = tmp_union;
        else
            unionL = my_union_implementation(unionL, tmp_union);

        *left = real_index;
        ++left;
        ++(v->spl_nleft);
    }
    else
    {
        /*
         * Same on the right
         */
    }
}

v->spl_ldatum = DataTypeGetDatum(unionL);
v->spl_rdatum = DataTypeGetDatum(unionR);
PG_RETURN_POINTER(v);
}

```

Notice that the `picksplit` function's result is delivered by modifying the passed-in `v` structure. The return value *per se* is ignored, though it's conventional to pass back the address of `v`.

Like `penalty`, the `picksplit` function is crucial to good performance of the index. Designing suitable `penalty` and `picksplit` implementations is where the challenge of implementing well-performing GiST indexes lies.

same

Returns true if two index entries are identical, false otherwise. (An "index entry" is a value of the index's storage type, not necessarily the original indexed column's type.)

The SQL declaration of the function must look like this:

```

CREATE OR REPLACE FUNCTION my_same(storage_type, storage_type, internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;

```

And the matching code in the C module could then follow this skeleton:

```

PG_FUNCTION_INFO_V1(my_same);

Datum
my_same(PG_FUNCTION_ARGS)

```

```

{
    prefix_range *v1 = PG_GETARG_PREFIX_RANGE_P(0);
    prefix_range *v2 = PG_GETARG_PREFIX_RANGE_P(1);
    bool          *result = (bool *) PG_GETARG_POINTER(2);

    *result = my_eq(v1, v2);
    PG_RETURN_POINTER(result);
}

```

For historical reasons, the same function doesn't just return a Boolean result; instead it has to store the flag at the location indicated by the third argument. The return value per se is ignored, though it's conventional to pass back the address of that argument.

distance

Given an index entry *p* and a query value *q*, this function determines the index entry's "distance" from the query value. This function must be supplied if the operator class contains any ordering operators. A query using the ordering operator will be implemented by returning index entries with the smallest "distance" values first, so the results must be consistent with the operator's semantics. For a leaf index entry the result just represents the distance to the index entry; for an internal tree node, the result must be the smallest distance that any child entry could have.

The SQL declaration of the function must look like this:

```

CREATE OR REPLACE FUNCTION my_distance(internal, data_type, smallint, oid, internal)
RETURNS float8
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;

```

And the matching code in the C module could then follow this skeleton:

```

PG_FUNCTION_INFO_V1(my_distance);

Datum
my_distance(PG_FUNCTION_ARGS)
{
    GISTENTRY *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
    data_type *query = PG_GETARG_DATA_TYPE_P(1);
    StrategyNumber strategy = (StrategyNumber) PG_GETARG_UINT16(2);
    /* Oid subtype = PG_GETARG_OID(3); */
    /* bool *recheck = (bool *) PG_GETARG_POINTER(4); */
    data_type *key = DatumGetDataTypes(entry->key);
    double      retval;

    /*
     * determine return value as a function of strategy, key and query.
     */

    PG_RETURN_FLOAT8(retval);
}

```

The arguments to the `distance` function are identical to the arguments of the `consistent` function.

Some approximation is allowed when determining the distance, so long as the result is never greater than the entry's actual distance. Thus, for example, distance to a bounding box is usually sufficient in geometric applications. For an internal tree node, the distance returned must not be greater than the distance to any of the child nodes. If the returned distance is not exact, the function must set `*recheck` to true. (This is not necessary for internal tree nodes; for them, the calculation is always assumed to be inexact.) In this case the executor will calculate the accurate distance after fetching the tuple from the heap, and reorder the tuples if necessary.

If the distance function returns `*recheck = true` for any leaf node, the original ordering operator's return type must be `float8` or `float4`, and the distance function's result values must be comparable

to those of the original ordering operator, since the executor will sort using both distance function results and recalculated ordering-operator results. Otherwise, the distance function's result values can be any finite `float8` values, so long as the relative order of the result values matches the order returned by the ordering operator. (Infinity and minus infinity are used internally to handle cases such as nulls, so it is not recommended that `distance` functions return these values.)

#### `fetch`

Converts the compressed index representation of a data item into the original data type, for index-only scans. The returned data must be an exact, non-lossy copy of the originally indexed value.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_fetch(internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

The argument is a pointer to a `GISTENTRY` struct. On entry, its `key` field contains a non-NULL leaf datum in compressed form. The return value is another `GISTENTRY` struct, whose `key` field contains the same datum in its original, uncompressed form. If the opclass's `compress` function does nothing for leaf entries, the `fetch` method can return the argument as-is. Or, if the opclass does not have a `compress` function, the `fetch` method can be omitted as well, since it would necessarily be a no-op.

The matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_fetch);

Datum
my_fetch(PG_FUNCTION_ARGS)
{
    GISTENTRY *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
    input_data_type *in = DatumGetPointer(entry->key);
    fetched_data_type *fetched_data;
    GISTENTRY *retval;

    retval = palloc(sizeof(GISTENTRY));
    fetched_data = palloc(sizeof(fetched_data_type));

    /*
     * Convert 'fetched_data' into the a Datum of the original datatype.
     */

    /* fill *retval from fetched_data. */
    gistentryinit(*retval, PointerGetDatum(converted_datum),
                  entry->rel, entry->page, entry->offset, FALSE);

    PG_RETURN_POINTER(retval);
}
```

If the `compress` method is lossy for leaf entries, the operator class cannot support index-only scans, and must not define a `fetch` function.

#### `options`

Allows definition of user-visible parameters that control operator class behavior.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_options(internal)
RETURNS void
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

The function is passed a pointer to a *local\_relopts* struct, which needs to be filled with a set of operator class specific options. The options can be accessed from other support functions using the `PG_HAS_OPCLASS_OPTIONS()` and `PG_GET_OPCLASS_OPTIONS()` macros.

An example implementation of `my_options()` and parameters use from other support functions are given below:

```
typedef enum MyEnumType
{
    MY_ENUM_ON,
    MY_ENUM_OFF,
    MY_ENUM_AUTO
} MyEnumType;

typedef struct
{
    int32    vl_len_;    /* varlena header (do not touch directly!) */
    int      int_param; /* integer parameter */
    double   real_param; /* real parameter */
    MyEnumType enum_param; /* enum parameter */
    int      str_param; /* string parameter */
} MyOptionsStruct;

/* String representation of enum values */
static relopt_enum_elt_def myEnumValues[] =
{
    {"on", MY_ENUM_ON},
    {"off", MY_ENUM_OFF},
    {"auto", MY_ENUM_AUTO},
    {(const char *) NULL} /* list terminator */
};

static char *str_param_default = "default";

/*
 * Sample validator: checks that string is not longer than 8 bytes.
 */
static void
validate_my_string_relopt(const char *value)
{
    if (strlen(value) > 8)
        ereport(ERROR,
                (errcode(ERRCODE_INVALID_PARAMETER_VALUE),
                 errmsg("str_param must be at most 8 bytes")));
}

/*
 * Sample filler: switches characters to lower case.
 */
static Size
fill_my_string_relopt(const char *value, void *ptr)
{
    char    *tmp = str_tolower(value, strlen(value), DEFAULT_COLLATION_OID);
    int      len = strlen(tmp);

    if (ptr)
        strcpy((char *) ptr, tmp);

    pfree(tmp);
}
```

```

    return len + 1;
}

PG_FUNCTION_INFO_V1(my_options);

Datum
my_options(PG_FUNCTION_ARGS)
{
    local_relopts *relopts = (local_relopts *) PG_GETARG_POINTER(0);

    init_local_reloptions(relopts, sizeof(MyOptionsStruct));
    add_local_int_reloption(relopts, "int_param", "integer parameter",
                           100, 0, 1000000,
                           offsetof(MyOptionsStruct, int_param));
    add_local_real_reloption(relopts, "real_param", "real parameter",
                              1.0, 0.0, 1000000.0,
                              offsetof(MyOptionsStruct, real_param));
    add_local_enum_reloption(relopts, "enum_param", "enum parameter",
                              myEnumValues, MY_ENUM_ON,
                              "Valid values are: \"on\", \"off\" and \"auto\".",
                              offsetof(MyOptionsStruct, enum_param));
    add_local_string_reloption(relopts, "str_param", "string parameter",
                                str_param_default,
                                &validate_my_string_relopt,
                                &fill_my_string_relopt,
                                offsetof(MyOptionsStruct, str_param));

    PG_RETURN_VOID();
}

PG_FUNCTION_INFO_V1(my_compress);

Datum
my_compress(PG_FUNCTION_ARGS)
{
    int    int_param = 100;
    double real_param = 1.0;
    MyEnumType enum_param = MY_ENUM_ON;
    char   *str_param = str_param_default;

    /*
     * Normally, when opclass contains 'options' method, then options are always
     * passed to support functions. However, if you add 'options' method to
     * existing opclass, previously defined indexes have no options, so the
     * check is required.
     */
    if (PG_HAS_OPCLASS_OPTIONS())
    {
        MyOptionsStruct *options = (MyOptionsStruct *) PG_GET_OPCLASS_OPTIONS();

        int_param = options->int_param;
        real_param = options->real_param;
        enum_param = options->enum_param;
        str_param = GET_STRING_RELOPTION(options, str_param);
    }

    /* the rest implementation of support function */
}

```

Since the representation of the key in GiST is flexible, it may depend on user-specified parameters. For instance, the length of key signature may be specified. See `gtsvector_options()` for example.

All the GiST support methods are normally called in short-lived memory contexts; that is, `CurrentMemoryContext` will get reset after each tuple is processed. It is therefore not very important to worry about `pfree`'ing everything you `palloc`. However, in some cases it's useful for a support method to cache data across repeated calls. To do that, allocate the longer-lived data in `fcinfo->flinfo->fn_mcxt`, and keep a pointer to it in `fcinfo->flinfo->fn_extra`. Such data will survive for the life of the index operation (e.g., a single GiST index scan, index build, or index tuple insertion). Be careful to `pfree` the previous value when replacing a `fn_extra` value, or the leak will accumulate for the duration of the operation.

## 60.4. Implementation

### 60.4.1. GiST Buffering Build

Building large GiST indexes by simply inserting all the tuples tends to be slow, because if the index tuples are scattered across the index and the index is large enough to not fit in cache, the insertions need to perform a lot of random I/O. Beginning in version 9.2, PostgreSQL supports a more efficient method to build GiST indexes based on buffering, which can dramatically reduce the number of random I/Os needed for non-ordered data sets. For well-ordered data sets the benefit is smaller or non-existent, because only a small number of pages receive new tuples at a time, and those pages fit in cache even if the index as whole does not.

However, buffering index build needs to call the `penalty` function more often, which consumes some extra CPU resources. Also, the buffers used in the buffering build need temporary disk space, up to the size of the resulting index. Buffering can also influence the quality of the resulting index, in both positive and negative directions. That influence depends on various factors, like the distribution of the input data and the operator class implementation.

By default, a GiST index build switches to the buffering method when the index size reaches [effective\\_cache\\_size](#). It can be manually turned on or off by the `buffering` parameter to the `CREATE INDEX` command. The default behavior is good for most cases, but turning buffering off might speed up the build somewhat if the input data is ordered.

## 60.5. Examples

The Postgres Pro core system currently provides text search support (indexing for `tsvector` and `tsquery`) as well as R-Tree equivalent functionality for some of the built-in geometric data types. The following `contrib` modules also contain GiST operator classes:

`btree_gist`

B-tree equivalent functionality for several data types

`cube`

Indexing for multidimensional cubes

`hstore`

Module for storing (key, value) pairs

`intarray`

RD-Tree for one-dimensional array of `int4` values

`ltree`

Indexing for tree-like structures

pg\_trgm

Text similarity using trigram matching

seg

Indexing for “float ranges”

---

# Chapter 61. SP-GiST Indexes

## 61.1. Introduction

SP-GiST is an abbreviation for space-partitioned GiST. SP-GiST supports partitioned search trees, which facilitate development of a wide range of different non-balanced data structures, such as quad-trees, k-d trees, and radix trees (tries). The common feature of these structures is that they repeatedly divide the search space into partitions that need not be of equal size. Searches that are well matched to the partitioning rule can be very fast.

These popular data structures were originally developed for in-memory usage. In main memory, they are usually designed as a set of dynamically allocated nodes linked by pointers. This is not suitable for direct storing on disk, since these chains of pointers can be rather long which would require too many disk accesses. In contrast, disk-based data structures should have a high fanout to minimize I/O. The challenge addressed by SP-GiST is to map search tree nodes to disk pages in such a way that a search need access only a few disk pages, even if it traverses many nodes.

Like GiST, SP-GiST is meant to allow the development of custom data types with the appropriate access methods, by an expert in the domain of the data type, rather than a database expert.

Some of the information here is derived from Purdue University's SP-GiST Indexing Project [web site](#). The SP-GiST implementation in Postgres Pro is primarily maintained by Teodor Sigaev and Oleg Bartunov, and there is more information on their [web site](#).

## 61.2. Built-in Operator Classes

The core Postgres Pro distribution includes the SP-GiST operator classes shown in [Table 61.1](#).

**Table 61.1. Built-in SP-GiST Operator Classes**

Name	Indexed Data Type	Indexable Operators	Ordering Operators
kd_point_ops	point	<< <@ <^ >> >^ ~=	<->
quad_point_ops	point	<< <@ <^ >> >^ ~=	<->
range_ops	any range type	&& &< &> - - << <@ = >> &@>	
box_ops	box	<< &< && &> >> ~= @> <@ &<  <<   >>  &>	<->
poly_ops	polygon	<< &< && &> >> ~= @> <@ &<  <<   >>  &>	<->
text_ops	text	< <= > >= ~<=~ ~<~ ~>=~ ~>~ ^@	
inet_ops	inet, cidr	&& >> >>= > >= <> << <<= < <= =	

Of the two operator classes for type `point`, `quad_point_ops` is the default. `kd_point_ops` supports the same operators but uses a different index data structure that may offer better performance in some applications.

The `quad_point_ops`, `kd_point_ops` and `poly_ops` operator classes support the `<->` ordering operator, which enables the k-nearest neighbor (k-NN) search over indexed point or polygon data sets.

## 61.3. Extensibility

SP-GiST offers an interface with a high level of abstraction, requiring the access method developer to implement only methods specific to a given data type. The SP-GiST core is responsible for efficient disk mapping and searching the tree structure. It also takes care of concurrency and logging considerations.

Leaf tuples of an SP-GiST tree contain values of the same data type as the indexed column. Leaf tuples at the root level will always contain the original indexed data value, but leaf tuples at lower levels might contain only a compressed representation, such as a suffix. In that case the operator class support functions must be able to reconstruct the original value using information accumulated from the inner tuples that are passed through to reach the leaf level.

Inner tuples are more complex, since they are branching points in the search tree. Each inner tuple contains a set of one or more *nodes*, which represent groups of similar leaf values. A node contains a downlink that leads either to another, lower-level inner tuple, or to a short list of leaf tuples that all lie on the same index page. Each node normally has a *label* that describes it; for example, in a radix tree the node label could be the next character of the string value. (Alternatively, an operator class can omit the node labels, if it works with a fixed set of nodes for all inner tuples; see [Section 61.4.2.](#)) Optionally, an inner tuple can have a *prefix* value that describes all its members. In a radix tree this could be the common prefix of the represented strings. The prefix value is not necessarily really a prefix, but can be any data needed by the operator class; for example, in a quad-tree it can store the central point that the four quadrants are measured with respect to. A quad-tree inner tuple would then also contain four nodes corresponding to the quadrants around this central point.

Some tree algorithms require knowledge of level (or depth) of the current tuple, so the SP-GiST core provides the possibility for operator classes to manage level counting while descending the tree. There is also support for incrementally reconstructing the represented value when that is needed, and for passing down additional data (called *traverse values*) during a tree descent.

### Note

The SP-GiST core code takes care of null entries. Although SP-GiST indexes do store entries for nulls in indexed columns, this is hidden from the index operator class code: no null index entries or search conditions will ever be passed to the operator class methods. (It is assumed that SP-GiST operators are strict and so cannot succeed for null values.) Null values are therefore not discussed further here.

There are five user-defined methods that an index operator class for SP-GiST must provide, and two are optional. All five mandatory methods follow the convention of accepting two `internal` arguments, the first of which is a pointer to a C struct containing input values for the support method, while the second argument is a pointer to a C struct where output values must be placed. Four of the mandatory methods just return `void`, since all their results appear in the output struct; but `leaf_consistent` returns a `boolean` result. The methods must not modify any fields of their input structs. In all cases, the output struct is initialized to zeroes before calling the user-defined method. The optional sixth method `compress` accepts a `datum` to be indexed as the only argument and returns a value suitable for physical storage in a leaf tuple. The optional seventh method `options` accepts an `internal` pointer to a C struct, where oclass-specific parameters should be placed, and returns `void`.

The five mandatory user-defined methods are:

`config`

Returns static information about the index implementation, including the data type OIDs of the prefix and node label data types.

The SQL declaration of the function must look like this:

```
CREATE FUNCTION my_config(internal, internal) RETURNS void ...
```

The first argument is a pointer to a `spgConfigIn` C struct, containing input data for the function. The second argument is a pointer to a `spgConfigOut` C struct, which the function must fill with result data.

```
typedef struct spgConfigIn
{
    Oid          attType;          /* Data type to be indexed */
```

```

} spgConfigIn;

typedef struct spgConfigOut
{
    Oid        prefixType;    /* Data type of inner-tuple prefixes */
    Oid        labelType;    /* Data type of inner-tuple node labels */
    Oid        leafType;     /* Data type of leaf-tuple values */
    bool       canReturnData; /* Opclass can reconstruct original data */
    bool       longValuesOK; /* Opclass can cope with values > 1 page */
} spgConfigOut;

```

`attType` is passed in order to support polymorphic index operator classes; for ordinary fixed-data-type operator classes, it will always have the same value and so can be ignored.

For operator classes that do not use prefixes, `prefixType` can be set to `VOIDOID`. Likewise, for operator classes that do not use node labels, `labelType` can be set to `VOIDOID`. `canReturnData` should be set true if the operator class is capable of reconstructing the originally-supplied index value. `longValuesOK` should be set true only when the `attType` is of variable length and the operator class is capable of segmenting long values by repeated suffixing (see [Section 61.4.1](#)).

`leafType` is typically the same as `attType`. For the reasons of backward compatibility, method `config` can leave `leafType` uninitialized; that would give the same effect as setting `leafType` equal to `attType`. When `attType` and `leafType` are different, then optional method `compress` must be provided. Method `compress` is responsible for transformation of datums to be indexed from `attType` to `leafType`. Note: both consistent functions will get `scankeys` unchanged, without transformation using `compress`.

choose

Chooses a method for inserting a new value into an inner tuple.

The SQL declaration of the function must look like this:

```
CREATE FUNCTION my_choose(internal, internal) RETURNS void ...
```

The first argument is a pointer to a `spgChooseIn` C struct, containing input data for the function. The second argument is a pointer to a `spgChooseOut` C struct, which the function must fill with result data.

```

typedef struct spgChooseIn
{
    Datum      datum;        /* original datum to be indexed */
    Datum      leafDatum;    /* current datum to be stored at leaf */
    int        level;        /* current level (counting from zero) */

    /* Data from current inner tuple */
    bool       allTheSame;   /* tuple is marked all-the-same? */
    bool       hasPrefix;   /* tuple has a prefix? */
    Datum      prefixDatum;  /* if so, the prefix value */
    int        nNodes;       /* number of nodes in the inner tuple */
    Datum      *nodeLabels;  /* node label values (NULL if none) */
} spgChooseIn;

typedef enum spgChooseResultType
{
    spgMatchNode = 1,        /* descend into existing node */
    spgAddNode,              /* add a node to the inner tuple */
    spgSplitTuple            /* split inner tuple (change its prefix) */
} spgChooseResultType;

typedef struct spgChooseOut
{

```

```

    spgChooseResultType resultType;      /* action code, see above */
    union
    {
        struct                          /* results for spgMatchNode */
        {
            int          nodeN;          /* descend to this node (index from 0) */
            int          levelAdd;       /* increment level by this much */
            Datum        restDatum;     /* new leaf datum */
        }          matchNode;
        struct                          /* results for spgAddNode */
        {
            Datum        nodeLabel;     /* new node's label */
            int          nodeN;          /* where to insert it (index from 0) */
        }          addNode;
        struct                          /* results for spgSplitTuple */
        {
            /* Info to form new upper-level inner tuple with one child tuple */
            bool          prefixHasPrefix; /* tuple should have a prefix? */
            Datum        prefixPrefixDatum; /* if so, its value */
            int          prefixNNodes;    /* number of nodes */
            Datum        *prefixNodeLabels; /* their labels (or NULL for
            * no labels) */
            int          childNodeN;     /* which node gets child tuple */

            /* Info to form new lower-level inner tuple with all old nodes */
            bool          postfixHasPrefix; /* tuple should have a prefix? */
            Datum        postfixPrefixDatum; /* if so, its value */
        }          splitTuple;
    }          result;
} spgChooseOut;

```

**datum** is the original datum of `spgConfigIn.attType` type that was to be inserted into the index. **leafDatum** is a value of `spgConfigOut.leafType` type, which is initially a result of method `compress` applied to `datum` when method `compress` is provided, or the same value as `datum` otherwise. **leafDatum** can change at lower levels of the tree if the `choose` or `picksplit` methods change it. When the insertion search reaches a leaf page, the current value of `leafDatum` is what will be stored in the newly created leaf tuple. **level** is the current inner tuple's level, starting at zero for the root level. **allTheSame** is true if the current inner tuple is marked as containing multiple equivalent nodes (see [Section 61.4.3](#)). **hasPrefix** is true if the current inner tuple contains a prefix; if so, **prefixDatum** is its value. **nNodes** is the number of child nodes contained in the inner tuple, and **nodeLabels** is an array of their label values, or NULL if there are no labels.

The `choose` function can determine either that the new value matches one of the existing child nodes, or that a new child node must be added, or that the new value is inconsistent with the tuple prefix and so the inner tuple must be split to create a less restrictive prefix.

If the new value matches one of the existing child nodes, set `resultType` to `spgMatchNode`. Set `nodeN` to the index (from zero) of that node in the node array. Set `levelAdd` to the increment in `level` caused by descending through that node, or leave it as zero if the operator class does not use levels. Set `restDatum` to equal `leafDatum` if the operator class does not modify datums from one level to the next, or otherwise set it to the modified value to be used as `leafDatum` at the next level.

If a new child node must be added, set `resultType` to `spgAddNode`. Set `nodeLabel` to the label to be used for the new node, and set `nodeN` to the index (from zero) at which to insert the node in the node array. After the node has been added, the `choose` function will be called again with the modified inner tuple; that call should result in an `spgMatchNode` result.

If the new value is inconsistent with the tuple prefix, set `resultType` to `spgSplitTuple`. This action moves all the existing nodes into a new lower-level inner tuple, and replaces the existing

inner tuple with a tuple having a single downlink pointing to the new lower-level inner tuple. Set `prefixHasPrefix` to indicate whether the new upper tuple should have a prefix, and if so set `prefixPrefixDatum` to the prefix value. This new prefix value must be sufficiently less restrictive than the original to accept the new value to be indexed. Set `prefixNNodes` to the number of nodes needed in the new tuple, and set `prefixNodeLabels` to a `palloc`'d array holding their labels, or to `NULL` if node labels are not required. Note that the total size of the new upper tuple must be no more than the total size of the tuple it is replacing; this constrains the lengths of the new prefix and new labels. Set `childNodeN` to the index (from zero) of the node that will downlink to the new lower-level inner tuple. Set `postfixHasPrefix` to indicate whether the new lower-level inner tuple should have a prefix, and if so set `postfixPrefixDatum` to the prefix value. The combination of these two prefixes and the downlink node's label (if any) must have the same meaning as the original prefix, because there is no opportunity to alter the node labels that are moved to the new lower-level tuple, nor to change any child index entries. After the node has been split, the `choose` function will be called again with the replacement inner tuple. That call may return an `spgAddNode` result, if no suitable node was created by the `spgSplitTuple` action. Eventually `choose` must return `spgMatchNode` to allow the insertion to descend to the next level.

`picksplit`

Decides how to create a new inner tuple over a set of leaf tuples.

The SQL declaration of the function must look like this:

```
CREATE FUNCTION my_picksplit(internal, internal) RETURNS void ...
```

The first argument is a pointer to a `spgPickSplitIn` C struct, containing input data for the function. The second argument is a pointer to a `spgPickSplitOut` C struct, which the function must fill with result data.

```
typedef struct spgPickSplitIn
{
    int          nTuples;          /* number of leaf tuples */
    Datum        *datums;          /* their datums (array of length nTuples) */
    int          level;           /* current level (counting from zero) */
} spgPickSplitIn;

typedef struct spgPickSplitOut
{
    bool          hasPrefix;       /* new inner tuple should have a prefix? */
    Datum        prefixDatum;     /* if so, its value */

    int          nNodes;          /* number of nodes for new inner tuple */
    Datum        *nodeLabels;     /* their labels (or NULL for no labels) */

    int          *mapTuplesToNodes; /* node index for each leaf tuple */
    Datum        *leafTupleDatums; /* datum to store in each new leaf tuple */
} spgPickSplitOut;
```

`nTuples` is the number of leaf tuples provided. `datums` is an array of their datum values of `spgConfigOut.leafType` type. `level` is the current level that all the leaf tuples share, which will become the level of the new inner tuple.

Set `hasPrefix` to indicate whether the new inner tuple should have a prefix, and if so set `prefixDatum` to the prefix value. Set `nNodes` to indicate the number of nodes that the new inner tuple will contain, and set `nodeLabels` to an array of their label values, or to `NULL` if node labels are not required. Set `mapTuplesToNodes` to an array that gives the index (from zero) of the node that each leaf tuple should be assigned to. Set `leafTupleDatums` to an array of the values to be stored in the new leaf tuples (these will be the same as the input `datums` if the operator class does not modify datums from one level to the next). Note that the `picksplit` function is responsible for `palloc`'ing the `nodeLabels`, `mapTuplesToNodes` and `leafTupleDatums` arrays.

If more than one leaf tuple is supplied, it is expected that the `picksplit` function will classify them into more than one node; otherwise it is not possible to split the leaf tuples across multiple pages, which is the ultimate purpose of this operation. Therefore, if the `picksplit` function ends up placing all the leaf tuples in the same node, the core SP-GiST code will override that decision and generate an inner tuple in which the leaf tuples are assigned at random to several identically-labeled nodes. Such a tuple is marked `allTheSame` to signify that this has happened. The `choose` and `inner_consistent` functions must take suitable care with such inner tuples. See [Section 61.4.3](#) for more information.

`picksplit` can be applied to a single leaf tuple only in the case that the `config` function set `longValuesOK` to true and a larger-than-a-page input value has been supplied. In this case the point of the operation is to strip off a prefix and produce a new, shorter leaf datum value. The call will be repeated until a leaf datum short enough to fit on a page has been produced. See [Section 61.4.1](#) for more information.

`inner_consistent`

Returns set of nodes (branches) to follow during tree search.

The SQL declaration of the function must look like this:

```
CREATE FUNCTION my_inner_consistent(internal, internal) RETURNS void ...
```

The first argument is a pointer to a `spgInnerConsistentIn` C struct, containing input data for the function. The second argument is a pointer to a `spgInnerConsistentOut` C struct, which the function must fill with result data.

```
typedef struct spgInnerConsistentIn
{
    ScanKey      scankeys;          /* array of operators and comparison values */
    ScanKey      orderbys;         /* array of ordering operators and comparison
    * values */
    int          nkeys;            /* length of scankeys array */
    int          norderbys;       /* length of orderbys array */

    Datum        reconstructedValue; /* value reconstructed at parent */
    void         *traversalValue; /* opclass-specific traverse value */
    MemoryContext traversalMemoryContext; /* put new traverse values here */
    int          level;           /* current level (counting from zero) */
    bool         returnData;     /* original data must be returned? */

    /* Data from current inner tuple */
    bool         allTheSame;      /* tuple is marked all-the-same? */
    bool         hasPrefix;      /* tuple has a prefix? */
    Datum        prefixDatum;    /* if so, the prefix value */
    int          nNodes;         /* number of nodes in the inner tuple */
    Datum        *nodeLabels;    /* node label values (NULL if none) */
} spgInnerConsistentIn;

typedef struct spgInnerConsistentOut
{
    int          nNodes;          /* number of child nodes to be visited */
    int          *nodeNumbers;    /* their indexes in the node array */
    int          *levelAdds;     /* increment level by this much for each */
    Datum        *reconstructedValues; /* associated reconstructed values */
    void         **traversalValues; /* opclass-specific traverse values */
    double       **distances;    /* associated distances */
} spgInnerConsistentOut;
```

The array `scankeys`, of length `nkeys`, describes the index search condition(s). These conditions are combined with AND — only index entries that satisfy all of them are interesting. (Note that `nkeys = 0` implies that all index entries satisfy the query.) Usually the consistent function only cares

about the `sk_strategy` and `sk_argument` fields of each array entry, which respectively give the indexable operator and comparison value. In particular it is not necessary to check `sk_flags` to see if the comparison value is NULL, because the SP-GiST core code will filter out such conditions. The array `orderbys`, of length `norderbys`, describes ordering operators (if any) in the same manner. `reconstructedValue` is the value reconstructed for the parent tuple; it is (Datum) 0 at the root level or if the `inner_consistent` function did not provide a value at the parent level. `reconstructedValue` is always of `spgConfigOut.leafType` type. `traversalValue` is a pointer to any traverse data passed down from the previous call of `inner_consistent` on the parent index tuple, or NULL at the root level. `traversalMemoryContext` is the memory context in which to store output traverse values (see below). `level` is the current inner tuple's level, starting at zero for the root level. `returnData` is true if reconstructed data is required for this query; this will only be so if the `config` function asserted `canReturnData`. `allTheSame` is true if the current inner tuple is marked "all-the-same"; in this case all the nodes have the same label (if any) and so either all or none of them match the query (see [Section 61.4.3](#)). `hasPrefix` is true if the current inner tuple contains a prefix; if so, `prefixDatum` is its value. `nNodes` is the number of child nodes contained in the inner tuple, and `nodeLabels` is an array of their label values, or NULL if the nodes do not have labels.

`nNodes` must be set to the number of child nodes that need to be visited by the search, and `nodeNumbers` must be set to an array of their indexes. If the operator class keeps track of levels, set `levelAdds` to an array of the level increments required when descending to each node to be visited. (Often these increments will be the same for all the nodes, but that's not necessarily so, so an array is used.) If value reconstruction is needed, set `reconstructedValues` to an array of the values of `spgConfigOut.leafType` type reconstructed for each child node to be visited; otherwise, leave `reconstructedValues` as NULL. If ordered search is performed, set `distances` to an array of distance values according to `orderbys` array (nodes with lowest distances will be processed first). Leave it NULL otherwise. If it is desired to pass down additional out-of-band information ("traverse values") to lower levels of the tree search, set `traversalValues` to an array of the appropriate traverse values, one for each child node to be visited; otherwise, leave `traversalValues` as NULL. Note that the `inner_consistent` function is responsible for `palloc`'ing the `nodeNumbers`, `levelAdds`, `distances`, `reconstructedValues`, and `traversalValues` arrays in the current memory context. However, any output traverse values pointed to by the `traversalValues` array should be allocated in `traversalMemoryContext`. Each traverse value must be a single `palloc`'d chunk.

`leaf_consistent`

Returns true if a leaf tuple satisfies a query.

The SQL declaration of the function must look like this:

```
CREATE FUNCTION my_leaf_consistent(internal, internal) RETURNS bool ...
```

The first argument is a pointer to a `spgLeafConsistentIn` C struct, containing input data for the function. The second argument is a pointer to a `spgLeafConsistentOut` C struct, which the function must fill with result data.

```
typedef struct spgLeafConsistentIn
{
    ScanKey      scankeys;          /* array of operators and comparison values */
    ScanKey      orderbys;          /* array of ordering operators and comparison
                                   * values */
    int          nkeys;              /* length of scankeys array */
    int          norderbys;         /* length of orderbys array */

    Datum        reconstructedValue; /* value reconstructed at parent */
    void         *traversalValue;    /* opclass-specific traverse value */
    int          level;              /* current level (counting from zero) */
    bool         returnData;         /* original data must be returned? */

    Datum        leafDatum;          /* datum in leaf tuple */
} spgLeafConsistentIn;
```

```
typedef struct spgLeafConsistentOut
{
    Datum        leafValue;          /* reconstructed original data, if any */
    bool         recheck;            /* set true if operator must be rechecked */
    bool         recheckDistances;  /* set true if distances must be rechecked */
    double       *distances;        /* associated distances */
} spgLeafConsistentOut;
```

The array `scankeys`, of length `nkeys`, describes the index search condition(s). These conditions are combined with AND — only index entries that satisfy all of them satisfy the query. (Note that `nkeys = 0` implies that all index entries satisfy the query.) Usually the consistent function only cares about the `sk_strategy` and `sk_argument` fields of each array entry, which respectively give the indexable operator and comparison value. In particular it is not necessary to check `sk_flags` to see if the comparison value is NULL, because the SP-GiST core code will filter out such conditions. The array `orderbys`, of length `norderbys`, describes the ordering operators in the same manner. `reconstructedValue` is the value reconstructed for the parent tuple; it is (Datum) 0 at the root level or if the `inner_consistent` function did not provide a value at the parent level. `reconstructedValue` is always of `spgConfigOut.leafType` type. `traversalValue` is a pointer to any traverse data passed down from the previous call of `inner_consistent` on the parent index tuple, or NULL at the root level. `level` is the current leaf tuple's level, starting at zero for the root level. `returnData` is true if reconstructed data is required for this query; this will only be so if the `config` function asserted `canReturnData`. `leafDatum` is the key value of `spgConfigOut.leafType` stored in the current leaf tuple.

The function must return `true` if the leaf tuple matches the query, or `false` if not. In the `true` case, if `returnData` is `true` then `leafValue` must be set to the value of `spgConfigIn.attType` type originally supplied to be indexed for this leaf tuple. Also, `recheck` may be set to `true` if the match is uncertain and so the operator(s) must be re-applied to the actual heap tuple to verify the match. If ordered search is performed, set `distances` to an array of distance values according to `orderbys` array. Leave it NULL otherwise. If at least one of returned distances is not exact, set `recheckDistances` to `true`. In this case, the executor will calculate the exact distances after fetching the tuple from the heap, and will reorder the tuples if needed.

The optional user-defined method are:

`Datum compress(Datum in)`

Converts the data item into a format suitable for physical storage in a leaf tuple of index page. It accepts `spgConfigIn.attType` value and returns `spgConfigOut.leafType` value. Output value should not be toasted.

`options`

Defines a set of user-visible parameters that control operator class behavior.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_options(internal)
RETURNS void
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

The function is passed a pointer to a `local_relopts` struct, which needs to be filled with a set of operator class specific options. The options can be accessed from other support functions using the `PG_HAS_OPCLASS_OPTIONS()` and `PG_GET_OPCLASS_OPTIONS()` macros.

Since the representation of the key in SP-GiST is flexible, it may depend on user-specified parameters.

All the SP-GiST support methods are normally called in a short-lived memory context; that is, `CurrentMemoryContext` will be reset after processing of each tuple. It is therefore not very important to

worry about pfree'ing everything you palloc. (The `config` method is an exception: it should try to avoid leaking memory. But usually the `config` method need do nothing but assign constants into the passed parameter struct.)

If the indexed column is of a collatable data type, the index collation will be passed to all the support methods, using the standard `PG_GET_COLLATION()` mechanism.

## 61.4. Implementation

This section covers implementation details and other tricks that are useful for implementers of SP-GiST operator classes to know.

### 61.4.1. SP-GiST Limits

Individual leaf tuples and inner tuples must fit on a single index page (8kB by default). Therefore, when indexing values of variable-length data types, long values can only be supported by methods such as radix trees, in which each level of the tree includes a prefix that is short enough to fit on a page, and the final leaf level includes a suffix also short enough to fit on a page. The operator class should set `longValuesOK` to true only if it is prepared to arrange for this to happen. Otherwise, the SP-GiST core will reject any request to index a value that is too large to fit on an index page.

Likewise, it is the operator class's responsibility that inner tuples do not grow too large to fit on an index page; this limits the number of child nodes that can be used in one inner tuple, as well as the maximum size of a prefix value.

Another limitation is that when an inner tuple's node points to a set of leaf tuples, those tuples must all be in the same index page. (This is a design decision to reduce seeking and save space in the links that chain such tuples together.) If the set of leaf tuples grows too large for a page, a split is performed and an intermediate inner tuple is inserted. For this to fix the problem, the new inner tuple *must* divide the set of leaf values into more than one node group. If the operator class's `picksplit` function fails to do that, the SP-GiST core resorts to extraordinary measures described in [Section 61.4.3](#).

When `longValuesOK` is true, it is expected that successive levels of the SP-GiST tree will absorb more and more information into the prefixes and node labels of the inner tuples, making the required leaf datum smaller and smaller, so that eventually it will fit on a page. To prevent bugs in operator classes from causing infinite insertion loops, the SP-GiST core will raise an error if the leaf datum does not become any smaller within ten cycles of `choose` method calls.

### 61.4.2. SP-GiST Without Node Labels

Some tree algorithms use a fixed set of nodes for each inner tuple; for example, in a quad-tree there are always exactly four nodes corresponding to the four quadrants around the inner tuple's centroid point. In such a case the code typically works with the nodes by number, and there is no need for explicit node labels. To suppress node labels (and thereby save some space), the `picksplit` function can return NULL for the `nodeLabels` array, and likewise the `choose` function can return NULL for the `prefixNodeLabels` array during a `spgSplitTuple` action. This will in turn result in `nodeLabels` being NULL during subsequent calls to `choose` and `inner_consistent`. In principle, node labels could be used for some inner tuples and omitted for others in the same index.

When working with an inner tuple having unlabeled nodes, it is an error for `choose` to return `spgAddNode`, since the set of nodes is supposed to be fixed in such cases.

### 61.4.3. “All-the-Same” Inner Tuples

The SP-GiST core can override the results of the operator class's `picksplit` function when `picksplit` fails to divide the supplied leaf values into at least two node categories. When this happens, the new inner tuple is created with multiple nodes that each have the same label (if any) that `picksplit` gave to the one node it did use, and the leaf values are divided at random among these equivalent nodes. The `allTheSame` flag is set on the inner tuple to warn the `choose` and `inner_consistent` functions that the tuple does not have the node set that they might otherwise expect.

When dealing with an `allTheSame` tuple, a `choose` result of `spgMatchNode` is interpreted to mean that the new value can be assigned to any of the equivalent nodes; the core code will ignore the supplied `nodeN` value and descend into one of the nodes at random (so as to keep the tree balanced). It is an error for `choose` to return `spgAddNode`, since that would make the nodes not all equivalent; the `spgSplitTuple` action must be used if the value to be inserted doesn't match the existing nodes.

When dealing with an `allTheSame` tuple, the `inner_consistent` function should return either all or none of the nodes as targets for continuing the index search, since they are all equivalent. This may or may not require any special-case code, depending on how much the `inner_consistent` function normally assumes about the meaning of the nodes.

---

# Chapter 62. GIN Indexes

## 62.1. Introduction

GIN stands for Generalized Inverted Index. GIN is designed for handling cases where the items to be indexed are composite values, and the queries to be handled by the index need to search for element values that appear within the composite items. For example, the items could be documents, and the queries could be searches for documents containing specific words.

We use the word *item* to refer to a composite value that is to be indexed, and the word *key* to refer to an element value. GIN always stores and searches for keys, not item values per se.

A GIN index stores a set of (key, posting list) pairs, where a *posting list* is a set of row IDs in which the key occurs. The same row ID can appear in multiple posting lists, since an item can contain more than one key. Each key value is stored only once, so a GIN index is very compact for cases where the same key appears many times.

GIN is generalized in the sense that the GIN access method code does not need to know the specific operations that it accelerates. Instead, it uses custom strategies defined for particular data types. The strategy defines how keys are extracted from indexed items and query conditions, and how to determine whether a row that contains some of the key values in a query actually satisfies the query.

One advantage of GIN is that it allows the development of custom data types with the appropriate access methods, by an expert in the domain of the data type, rather than a database expert. This is much the same advantage as using GiST.

The GIN implementation in Postgres Pro is primarily maintained by Teodor Sigaev and Oleg Bartunov. There is more information about GIN on their [website](#).

## 62.2. Built-in Operator Classes

The core Postgres Pro distribution includes the GIN operator classes shown in [Table 62.1](#). (Some of the optional modules described in [Appendix F](#) provide additional GIN operator classes.)

**Table 62.1. Built-in GIN Operator Classes**

Name	Indexed Data Type	Indexable Operators
array_ops	anyarray	&& <@ = @>
jsonb_ops	jsonb	? ?& ?  @> @? @@
jsonb_path_ops	jsonb	@> @? @@
tsvector_ops	tsvector	@@ @@@

Of the two operator classes for type `jsonb`, `jsonb_ops` is the default. `jsonb_path_ops` supports fewer operators but offers better performance for those operators. See [Section 8.14.4](#) for details.

## 62.3. Extensibility

The GIN interface has a high level of abstraction, requiring the access method implementer only to implement the semantics of the data type being accessed. The GIN layer itself takes care of concurrency, logging and searching the tree structure.

All it takes to get a GIN access method working is to implement a few user-defined methods, which define the behavior of keys in the tree and the relationships between keys, indexed items, and indexable queries. In short, GIN combines extensibility with generality, code reuse, and a clean interface.

There are two methods that an operator class for GIN must provide:

```
Datum *extractValue(Datum itemValue, int32 *nkeys, bool **nullFlags)
```

Returns a palloc'd array of keys given an item to be indexed. The number of returned keys must be stored into `*nkeys`. If any of the keys can be null, also palloc an array of `*nkeys` bool fields, store its address at `*nullFlags`, and set these null flags as needed. `*nullFlags` can be left `NULL` (its initial value) if all keys are non-null. The return value can be `NULL` if the item contains no keys.

```
Datum *extractQuery(Datum query, int32 *nkeys, StrategyNumber n, bool **pmatch, Pointer
**extra_data, bool **nullFlags, int32 *searchMode)
```

Returns a palloc'd array of keys given a value to be queried; that is, `query` is the value on the right-hand side of an indexable operator whose left-hand side is the indexed column. `n` is the strategy number of the operator within the operator class (see [Section 35.16.2](#)). Often, `extractQuery` will need to consult `n` to determine the data type of `query` and the method it should use to extract key values. The number of returned keys must be stored into `*nkeys`. If any of the keys can be null, also palloc an array of `*nkeys` bool fields, store its address at `*nullFlags`, and set these null flags as needed. `*nullFlags` can be left `NULL` (its initial value) if all keys are non-null. The return value can be `NULL` if the `query` contains no keys.

`searchMode` is an output argument that allows `extractQuery` to specify details about how the search will be done. If `*searchMode` is set to `GIN_SEARCH_MODE_DEFAULT` (which is the value it is initialized to before call), only items that match at least one of the returned keys are considered candidate matches. If `*searchMode` is set to `GIN_SEARCH_MODE_INCLUDE_EMPTY`, then in addition to items containing at least one matching key, items that contain no keys at all are considered candidate matches. (This mode is useful for implementing is-subset-of operators, for example.) If `*searchMode` is set to `GIN_SEARCH_MODE_ALL`, then all non-null items in the index are considered candidate matches, whether they match any of the returned keys or not. (This mode is much slower than the other two choices, since it requires scanning essentially the entire index, but it may be necessary to implement corner cases correctly. An operator that needs this mode in most cases is probably not a good candidate for a GIN operator class.) The symbols to use for setting this mode are defined in `access/gin.h`.

`pmatch` is an output argument for use when partial match is supported. To use it, `extractQuery` must allocate an array of `*nkeys` bools and store its address at `*pmatch`. Each element of the array should be set to true if the corresponding key requires partial match, false if not. If `*pmatch` is set to `NULL` then GIN assumes partial match is not required. The variable is initialized to `NULL` before call, so this argument can simply be ignored by operator classes that do not support partial match.

`extra_data` is an output argument that allows `extractQuery` to pass additional data to the `consistent` and `comparePartial` methods. To use it, `extractQuery` must allocate an array of `*nkeys` pointers and store its address at `*extra_data`, then store whatever it wants to into the individual pointers. The variable is initialized to `NULL` before call, so this argument can simply be ignored by operator classes that do not require extra data. If `*extra_data` is set, the whole array is passed to the `consistent` method, and the appropriate element to the `comparePartial` method.

An operator class must also provide a function to check if an indexed item matches the query. It comes in two flavors, a Boolean `consistent` function, and a ternary `triConsistent` function. `triConsistent` covers the functionality of both, so providing `triConsistent` alone is sufficient. However, if the Boolean variant is significantly cheaper to calculate, it can be advantageous to provide both. If only the Boolean variant is provided, some optimizations that depend on refuting index items before fetching all the keys are disabled.

```
bool consistent(bool check[], StrategyNumber n, Datum query, int32 nkeys, Pointer
extra_data[], bool *recheck, Datum queryKeys[], bool nullFlags[])
```

Returns true if an indexed item satisfies the query operator with strategy number `n` (or might satisfy it, if the `recheck` indication is returned). This function does not have direct access to the indexed item's value, since GIN does not store items explicitly. Rather, what is available is knowledge about which key values extracted from the query appear in a given indexed item. The `check` array has length `nkeys`, which is the same as the number of keys previously returned by `extractQuery` for this `query`

datum. Each element of the `check` array is true if the indexed item contains the corresponding query key, i.e., if `(check[i] == true)` the *i*-th key of the `extractQuery` result array is present in the indexed item. The original query datum is passed in case the `consistent` method needs to consult it, and so are the `queryKeys[]` and `nullFlags[]` arrays previously returned by `extractQuery`. `extra_data` is the extra-data array returned by `extractQuery`, or `NULL` if none.

When `extractQuery` returns a null key in `queryKeys[]`, the corresponding `check[]` element is true if the indexed item contains a null key; that is, the semantics of `check[]` are like `IS NOT DISTINCT FROM`. The `consistent` function can examine the corresponding `nullFlags[]` element if it needs to tell the difference between a regular value match and a null match.

On success, `*recheck` should be set to true if the heap tuple needs to be rechecked against the query operator, or false if the index test is exact. That is, a false return value guarantees that the heap tuple does not match the query; a true return value with `*recheck` set to false guarantees that the heap tuple does match the query; and a true return value with `*recheck` set to true means that the heap tuple might match the query, so it needs to be fetched and rechecked by evaluating the query operator directly against the originally indexed item.

```
GinTernaryValue triConsistent(GinTernaryValue check[], StrategyNumber n, Datum query,
int32 nkeys, Pointer extra_data[], Datum queryKeys[], bool nullFlags[])
```

`triConsistent` is similar to `consistent`, but instead of Booleans in the `check` vector, there are three possible values for each key: `GIN_TRUE`, `GIN_FALSE` and `GIN_MAYBE`. `GIN_FALSE` and `GIN_TRUE` have the same meaning as regular Boolean values, while `GIN_MAYBE` means that the presence of that key is not known. When `GIN_MAYBE` values are present, the function should only return `GIN_TRUE` if the item certainly matches whether or not the index item contains the corresponding query keys. Likewise, the function must return `GIN_FALSE` only if the item certainly does not match, whether or not it contains the `GIN_MAYBE` keys. If the result depends on the `GIN_MAYBE` entries, i.e., the match cannot be confirmed or refuted based on the known query keys, the function must return `GIN_MAYBE`.

When there are no `GIN_MAYBE` values in the `check` vector, a `GIN_MAYBE` return value is the equivalent of setting the `recheck` flag in the Boolean `consistent` function.

In addition, GIN must have a way to sort the key values stored in the index. The operator class can define the sort ordering by specifying a comparison method:

```
int compare(Datum a, Datum b)
```

Compares two keys (not indexed items!) and returns an integer less than zero, zero, or greater than zero, indicating whether the first key is less than, equal to, or greater than the second. Null keys are never passed to this function.

Alternatively, if the operator class does not provide a `compare` method, GIN will look up the default btree operator class for the index key data type, and use its comparison function. It is recommended to specify the comparison function in a GIN operator class that is meant for just one data type, as looking up the btree operator class costs a few cycles. However, polymorphic GIN operator classes (such as `array_ops`) typically cannot specify a single comparison function.

An operator class for GIN can optionally supply the following methods:

```
int comparePartial(Datum partial_key, Datum key, StrategyNumber n, Pointer extra_data)
```

Compare a partial-match query key to an index key. Returns an integer whose sign indicates the result: less than zero means the index key does not match the query, but the index scan should continue; zero means that the index key does match the query; greater than zero indicates that the index scan should stop because no more matches are possible. The strategy number `n` of the operator that generated the partial match query is provided, in case its semantics are needed to determine when to end the scan. Also, `extra_data` is the corresponding element of the extra-data array made by `extractQuery`, or `NULL` if none. Null keys are never passed to this function.

```
void options(local_relopts *relopts)
```

Defines a set of user-visible parameters that control operator class behavior.

The `options` function is passed a pointer to a `local_relopts` struct, which needs to be filled with a set of operator class specific options. The options can be accessed from other support functions using the `PG_HAS_OPCLASS_OPTIONS()` and `PG_GET_OPCLASS_OPTIONS()` macros.

Since both key extraction of indexed values and representation of the key in GIN are flexible, they may depend on user-specified parameters.

To support “partial match” queries, an operator class must provide the `comparePartial` method, and its `extractQuery` method must set the `pmatch` parameter when a partial-match query is encountered. See [Section 62.4.2](#) for details.

The actual data types of the various `Datum` values mentioned above vary depending on the operator class. The item values passed to `extractValue` are always of the operator class's input type, and all key values must be of the class's `STORAGE` type. The type of the `query` argument passed to `extractQuery`, `consistent` and `triConsistent` is whatever is the right-hand input type of the class member operator identified by the strategy number. This need not be the same as the indexed type, so long as key values of the correct type can be extracted from it. However, it is recommended that the SQL declarations of these three support functions use the opclass's indexed data type for the `query` argument, even though the actual type might be something else depending on the operator.

## 62.4. Implementation

Internally, a GIN index contains a B-tree index constructed over keys, where each key is an element of one or more indexed items (a member of an array, for example) and where each tuple in a leaf page contains either a pointer to a B-tree of heap pointers (a “posting tree”), or a simple list of heap pointers (a “posting list”) when the list is small enough to fit into a single index tuple along with the key value. [Figure 62.1](#) illustrates these components of a GIN index.

As of PostgreSQL 9.1, null key values can be included in the index. Also, placeholder nulls are included in the index for indexed items that are null or contain no keys according to `extractValue`. This allows searches that should find empty items to do so.

Multicolumn GIN indexes are implemented by building a single B-tree over composite values (column number, key value). The key values for different columns can be of different types.

**Figure 62.1. GIN Internals**

### 62.4.1. GIN Fast Update Technique

Updating a GIN index tends to be slow because of the intrinsic nature of inverted indexes: inserting or updating one heap row can cause many inserts into the index (one for each key extracted from the indexed item). As of PostgreSQL 8.4, GIN is capable of postponing much of this work by inserting new tuples into a temporary, unsorted list of pending entries. When the table is vacuumed or autoanalyzed, or when `gin_clean_pending_list` function is called, or if the pending list becomes larger than `gin_pending_list_limit`, the entries are moved to the main GIN data structure using the same bulk insert techniques used during initial index creation. This greatly improves GIN index update speed, even counting the additional vacuum overhead. Moreover the overhead work can be done by a background process instead of in foreground query processing.

The main disadvantage of this approach is that searches must scan the list of pending entries in addition to searching the regular index, and so a large list of pending entries will slow searches significantly. Another disadvantage is that, while most updates are fast, an update that causes the pending list to become “too large” will incur an immediate cleanup cycle and thus be much slower than other updates. Proper use of autovacuum can minimize both of these problems.

If consistent response time is more important than update speed, use of pending entries can be disabled by turning off the `fastupdate` storage parameter for a GIN index. See [CREATE INDEX](#) for details.

### 62.4.2. Partial Match Algorithm

GIN can support “partial match” queries, in which the query does not determine an exact match for one or more keys, but the possible matches fall within a reasonably narrow range of key values (within the key sorting order determined by the `compare` support method). The `extractQuery` method, instead of returning a key value to be matched exactly, returns a key value that is the lower bound of the range to be searched, and sets the `pmatch` flag true. The key range is then scanned using the `comparePartial` method. `comparePartial` must return zero for a matching index key, less than zero for a non-match that is still within the range to be searched, or greater than zero if the index key is past the range that could match.

## 62.5. GIN Tips and Tricks

Create vs. insert

Insertion into a GIN index can be slow due to the likelihood of many keys being inserted for each item. So, for bulk insertions into a table it is advisable to drop the GIN index and recreate it after finishing bulk insertion.

As of PostgreSQL 8.4, this advice is less necessary since delayed indexing is used (see [Section 62.4.1](#) for details). But for very large updates it may still be best to drop and recreate the index.

[maintenance\\_work\\_mem](#)

Build time for a GIN index is very sensitive to the `maintenance_work_mem` setting; it doesn't pay to skimp on work memory during index creation.

[gin\\_pending\\_list\\_limit](#)

During a series of insertions into an existing GIN index that has `fastupdate` enabled, the system will clean up the pending-entry list whenever the list grows larger than `gin_pending_list_limit`. To avoid fluctuations in observed response time, it's desirable to have pending-list cleanup occur in the background (i.e., via autovacuum). Foreground cleanup operations can be avoided by increasing `gin_pending_list_limit` or making autovacuum more aggressive. However, enlarging the threshold of the cleanup operation means that if a foreground cleanup does occur, it will take even longer.

`gin_pending_list_limit` can be overridden for individual GIN indexes by changing storage parameters, which allows each GIN index to have its own cleanup threshold. For example, it's possible

to increase the threshold only for the GIN index which can be updated heavily, and decrease it otherwise.

### `gin_fuzzy_search_limit`

The primary goal of developing GIN indexes was to create support for highly scalable full-text search in Postgres Pro, and there are often situations when a full-text search returns a very large set of results. Moreover, this often happens when the query contains very frequent words, so that the large result set is not even useful. Since reading many tuples from the disk and sorting them could take a lot of time, this is unacceptable for production. (Note that the index search itself is very fast.)

To facilitate controlled execution of such queries, GIN has a configurable soft upper limit on the number of rows returned: the `gin_fuzzy_search_limit` configuration parameter. It is set to 0 (meaning no limit) by default. If a non-zero limit is set, then the returned set is a subset of the whole result set, chosen at random.

“Soft” means that the actual number of returned results could differ somewhat from the specified limit, depending on the query and the quality of the system's random number generator.

From experience, values in the thousands (e.g., 5000 — 20000) work well.

## 62.6. Limitations

GIN assumes that indexable operators are strict. This means that `extractValue` will not be called at all on a null item value (instead, a placeholder index entry is created automatically), and `extractQuery` will not be called on a null query value either (instead, the query is presumed to be unsatisfiable). Note however that null key values contained within a non-null composite item or query value are supported.

## 62.7. Examples

The core Postgres Pro distribution includes the GIN operator classes previously shown in [Table 62.1](#). The following `contrib` modules also contain GIN operator classes:

`btree_gin`

B-tree equivalent functionality for several data types

`hstore`

Module for storing (key, value) pairs

`intarray`

Enhanced support for `int[]`

`pg_trgm`

Text similarity using trigram matching

---

# Chapter 63. BRIN Indexes

## 63.1. Introduction

BRIN stands for Block Range Index. BRIN is designed for handling very large tables in which certain columns have some natural correlation with their physical location within the table. A *block range* is a group of pages that are physically adjacent in the table; for each block range, some summary info is stored by the index. For example, a table storing a store's sale orders might have a date column on which each order was placed, and most of the time the entries for earlier orders will appear earlier in the table as well; a table storing a ZIP code column might have all codes for a city grouped together naturally.

BRIN indexes can satisfy queries via regular bitmap index scans, and will return all tuples in all pages within each range if the summary info stored by the index is *consistent* with the query conditions. The query executor is in charge of rechecking these tuples and discarding those that do not match the query conditions — in other words, these indexes are lossy. Because a BRIN index is very small, scanning the index adds little overhead compared to a sequential scan, but may avoid scanning large parts of the table that are known not to contain matching tuples.

The specific data that a BRIN index will store, as well as the specific queries that the index will be able to satisfy, depend on the operator class selected for each column of the index. Data types having a linear sort order can have operator classes that store the minimum and maximum value within each block range, for instance; geometrical types might store the bounding box for all the objects in the block range.

The size of the block range is determined at index creation time by the `pages_per_range` storage parameter. The number of index entries will be equal to the size of the relation in pages divided by the selected value for `pages_per_range`. Therefore, the smaller the number, the larger the index becomes (because of the need to store more index entries), but at the same time the summary data stored can be more precise and more data blocks can be skipped during an index scan.

### 63.1.1. Index Maintenance

At the time of creation, all existing heap pages are scanned and a summary index tuple is created for each range, including the possibly-incomplete range at the end. As new pages are filled with data, page ranges that are already summarized will cause the summary information to be updated with data from the new tuples. When a new page is created that does not fall within the last summarized range, that range does not automatically acquire a summary tuple; those tuples remain unsynchronized until a summarization run is invoked later, creating initial summaries. This process can be invoked manually using the `brin_summarize_range(regclass, bigint)` or `brin_summarize_new_values(regclass)` functions; automatically when `VACUUM` processes the table; or by automatic summarization executed by `autovacuum`, as insertions occur. (This last trigger is disabled by default and can be enabled with the `autosummarize` parameter.) Conversely, a range can be de-summarized using the `brin_desummarize_range(regclass, bigint)` function, which is useful when the index tuple is no longer a very good representation because the existing values have changed.

When autosummarization is enabled, each time a page range is filled a request is sent to `autovacuum` for it to execute a targeted summarization for that range, to be fulfilled at the end of the next worker run on the same database. If the request queue is full, the request is not recorded and a message is sent to the server log:

```
LOG:  request for BRIN range summarization for index "brin_wi_idx" page 128 was not
      recorded
```

When this happens, the range will be summarized normally during the next regular vacuum of the table.

## 63.2. Built-in Operator Classes

The core Postgres Pro distribution includes the BRIN operator classes shown in [Table 63.1](#).

The *minmax* operator classes store the minimum and the maximum values appearing in the indexed column within the range. The *inclusion* operator classes store a value which includes the values in the indexed column within the range.

**Table 63.1. Built-in BRIN Operator Classes**

Name	Indexed Data Type	Indexable Operators
int8_minmax_ops	bigint	< <= = >= >
bit_minmax_ops	bit	< <= = >= >
varbit_minmax_ops	bit varying	< <= = >= >
box_inclusion_ops	box	<< &< && &> >> ~= @> <@ &<   <<    >>   &>
bytea_minmax_ops	bytea	< <= = >= >
bpchar_minmax_ops	character	< <= = >= >
char_minmax_ops	"char"	< <= = >= >
date_minmax_ops	date	< <= = >= >
float8_minmax_ops	double precision	< <= = >= >
inet_minmax_ops	inet	< <= = >= >
network_inclusion_ops	inet	&& >>= <<= = >> <<
int4_minmax_ops	integer	< <= = >= >
interval_minmax_ops	interval	< <= = >= >
macaddr_minmax_ops	macaddr	< <= = >= >
macaddr8_minmax_ops	macaddr8	< <= = >= >
name_minmax_ops	name	< <= = >= >
numeric_minmax_ops	numeric	< <= = >= >
pg_lsn_minmax_ops	pg_lsn	< <= = >= >
oid_minmax_ops	oid	< <= = >= >
range_inclusion_ops	any range type	<< &< && &> >> @> <@ - - = < <= = > >=
float4_minmax_ops	real	< <= = >= >
int2_minmax_ops	smallint	< <= = >= >
text_minmax_ops	text	< <= = >= >
tid_minmax_ops	tid	< <= = >= >
timestamp_minmax_ops	timestamp without time zone	< <= = >= >
timestamptz_minmax_ops	timestamp with time zone	< <= = >= >
time_minmax_ops	time without time zone	< <= = >= >
timetz_minmax_ops	time with time zone	< <= = >= >
uuid_minmax_ops	uuid	< <= = >= >

### 63.3. Extensibility

The BRIN interface has a high level of abstraction, requiring the access method implementer only to implement the semantics of the data type being accessed. The BRIN layer itself takes care of concurrency, logging and searching the index structure.

All it takes to get a BRIN access method working is to implement a few user-defined methods, which define the behavior of summary values stored in the index and the way they interact with scan keys. In short, BRIN combines extensibility with generality, code reuse, and a clean interface.

There are four methods that an operator class for BRIN must provide:

```
BrinOpcInfo *opcInfo(Oid type_oid)
```

Returns internal information about the indexed columns' summary data. The return value must point to a `malloc'd` `BrinOpcInfo`, which has this definition:

```
typedef struct BrinOpcInfo
{
    /* Number of columns stored in an index column of this opclass */
    uint16      oi_nstored;

    /* Opaque pointer for the opclass' private use */
    void        *oi_opaque;

    /* Type cache entries of the stored columns */
    TypeCacheEntry *oi_typcache[FLEXIBLE_ARRAY_MEMBER];
} BrinOpcInfo;
```

`BrinOpcInfo.oi_opaque` can be used by the operator class routines to pass information between support functions during an index scan.

```
bool consistent(BrinDesc *bdesc, BrinValues *column, ScanKey key)
```

Returns whether the `ScanKey` is consistent with the given indexed values for a range. The attribute number to use is passed as part of the scan key.

```
bool addValue(BrinDesc *bdesc, BrinValues *column, Datum newval, bool isnull)
```

Given an index tuple and an indexed value, modifies the indicated attribute of the tuple so that it additionally represents the new value. If any modification was done to the tuple, `true` is returned.

```
bool unionTuples(BrinDesc *bdesc, BrinValues *a, BrinValues *b)
```

Consolidates two index tuples. Given two index tuples, modifies the indicated attribute of the first of them so that it represents both tuples. The second tuple is not modified.

An operator class for BRIN can optionally specify the following method:

```
void options(local_relopts *relopts)
```

Defines a set of user-visible parameters that control operator class behavior.

The `options` function is passed a pointer to a `local_relopts` struct, which needs to be filled with a set of operator class specific options. The options can be accessed from other support functions using the `PG_HAS_OPCLASS_OPTIONS()` and `PG_GET_OPCLASS_OPTIONS()` macros.

Since both key extraction of indexed values and representation of the key in BRIN are flexible, they may depend on user-specified parameters.

The core distribution includes support for two types of operator classes: minmax and inclusion. Operator class definitions using them are shipped for in-core data types as appropriate. Additional operator classes can be defined by the user for other data types using equivalent definitions, without having to write any source code; appropriate catalog entries being declared is enough. Note that assumptions about the semantics of operator strategies are embedded in the support functions' source code.

Operator classes that implement completely different semantics are also possible, provided implementations of the four main support functions described above are written. Note that backwards compatibility across major releases is not guaranteed: for example, additional support functions might be required in later releases.

To write an operator class for a data type that implements a totally ordered set, it is possible to use the minmax support functions alongside the corresponding operators, as shown in [Table 63.2](#). All operator class members (functions and operators) are mandatory.

**Table 63.2. Function and Support Numbers for Minmax Operator Classes**

Operator class member	Object
Support Function 1	internal function <code>brin_minmax_opcinfo()</code>
Support Function 2	internal function <code>brin_minmax_add_value()</code>
Support Function 3	internal function <code>brin_minmax_consistent()</code>
Support Function 4	internal function <code>brin_minmax_union()</code>
Operator Strategy 1	operator less-than
Operator Strategy 2	operator less-than-or-equal-to
Operator Strategy 3	operator equal-to
Operator Strategy 4	operator greater-than-or-equal-to
Operator Strategy 5	operator greater-than

To write an operator class for a complex data type which has values included within another type, it's possible to use the inclusion support functions alongside the corresponding operators, as shown in [Table 63.3](#). It requires only a single additional function, which can be written in any language. More functions can be defined for additional functionality. All operators are optional. Some operators require other operators, as shown as dependencies on the table.

**Table 63.3. Function and Support Numbers for Inclusion Operator Classes**

Operator class member	Object	Dependency
Support Function 1	internal function <code>brin_inclusion_opcinfo()</code>	
Support Function 2	internal function <code>brin_inclusion_add_value()</code>	
Support Function 3	internal function <code>brin_inclusion_consistent()</code>	
Support Function 4	internal function <code>brin_inclusion_union()</code>	
Support Function 11	function to merge two elements	
Support Function 12	optional function to check whether two elements are mergeable	
Support Function 13	optional function to check if an element is contained within another	
Support Function 14	optional function to check whether an element is empty	
Operator Strategy 1	operator left-of	Operator Strategy 4
Operator Strategy 2	operator does-not-extend-to-the-right-of	Operator Strategy 5
Operator Strategy 3	operator overlaps	
Operator Strategy 4	operator does-not-extend-to-the-left-of	Operator Strategy 1
Operator Strategy 5	operator right-of	Operator Strategy 2
Operator Strategy 6, 18	operator same-as-or-equal-to	Operator Strategy 7
Operator Strategy 7, 13, 16, 24, 25	operator contains-or-equal-to	
Operator Strategy 8, 14, 26, 27	operator is-contained-by-or-equal-to	Operator Strategy 3

Operator class member	Object	Dependency
Operator Strategy 9	operator does-not-extend-above	Operator Strategy 11
Operator Strategy 10	operator is-below	Operator Strategy 12
Operator Strategy 11	operator is-above	Operator Strategy 9
Operator Strategy 12	operator does-not-extend-below	Operator Strategy 10
Operator Strategy 20	operator less-than	Operator Strategy 5
Operator Strategy 21	operator less-than-or-equal-to	Operator Strategy 5
Operator Strategy 22	operator greater-than	Operator Strategy 1
Operator Strategy 23	operator greater-than-or-equal-to	Operator Strategy 1

Support function numbers 1 through 10 are reserved for the BRIN internal functions, so the SQL level functions start with number 11. Support function number 11 is the main function required to build the index. It should accept two arguments with the same data type as the operator class, and return the union of them. The inclusion operator class can store union values with different data types if it is defined with the `STORAGE` parameter. The return value of the union function should match the `STORAGE` data type.

Support function numbers 12 and 14 are provided to support irregularities of built-in data types. Function number 12 is used to support network addresses from different families which are not mergeable. Function number 14 is used to support empty ranges. Function number 13 is an optional but recommended one, which allows the new value to be checked before it is passed to the union function. As the BRIN framework can shortcut some operations when the union is not changed, using this function can improve index performance.

Both minmax and inclusion operator classes support cross-data-type operators, though with these the dependencies become more complicated. The minmax operator class requires a full set of operators to be defined with both arguments having the same data type. It allows additional data types to be supported by defining extra sets of operators. Inclusion operator class operator strategies are dependent on another operator strategy as shown in [Table 63.3](#), or the same operator strategy as themselves. They require the dependency operator to be defined with the `STORAGE` data type as the left-hand-side argument and the other supported data type to be the right-hand-side argument of the supported operator. See `float4_minmax_ops` as an example of minmax, and `box_inclusion_ops` as an example of inclusion.

---

# Chapter 64. Hash Indexes

## 64.1. Overview

Postgres Pro includes an implementation of persistent on-disk hash indexes, which are fully crash recoverable. Any data type can be indexed by a hash index, including data types that do not have a well-defined linear ordering. Hash indexes store only the hash value of the data being indexed, thus there are no restrictions on the size of the data column being indexed.

Hash indexes support only single-column indexes and do not allow uniqueness checking.

Hash indexes support only the = operator, so WHERE clauses that specify range operations will not be able to take advantage of hash indexes.

Each hash index tuple stores just the 4-byte hash value, not the actual column value. As a result, hash indexes may be much smaller than B-trees when indexing longer data items such as UUIDs, URLs, etc. The absence of the column value also makes all hash index scans lossy. Hash indexes may take part in bitmap index scans and backward scans.

Hash indexes are best optimized for SELECT and UPDATE-heavy workloads that use equality scans on larger tables. In a B-tree index, searches must descend through the tree until the leaf page is found. In tables with millions of rows, this descent can increase access time to data. The equivalent of a leaf page in a hash index is referred to as a bucket page. In contrast, a hash index allows accessing the bucket pages directly, thereby potentially reducing index access time in larger tables. This reduction in "logical I/O" becomes even more pronounced on indexes/data larger than `shared_buffers/RAM`.

Hash indexes have been designed to cope with uneven distributions of hash values. Direct access to the bucket pages works well if the hash values are evenly distributed. When inserts mean that the bucket page becomes full, additional overflow pages are chained to that specific bucket page, locally expanding the storage for index tuples that match that hash value. When scanning a hash bucket during queries, we need to scan through all of the overflow pages. Thus an unbalanced hash index might actually be worse than a B-tree in terms of number of block accesses required, for some data.

As a result of the overflow cases, we can say that hash indexes are most suitable for unique, nearly unique data or data with a low number of rows per hash bucket. One possible way to avoid problems is to exclude highly non-unique values from the index using a partial index condition, but this may not be suitable in many cases.

Like B-Trees, hash indexes perform simple index tuple deletion. This is a deferred maintenance operation that deletes index tuples that are known to be safe to delete (those whose item identifier's `LP_DEAD` bit is already set). If an insert finds no space is available on a page we try to avoid creating a new overflow page by attempting to remove dead index tuples. Removal cannot occur if the page is pinned at that time. Deletion of dead index pointers also occurs during `VACUUM`.

If it can, `VACUUM` will also try to squeeze the index tuples onto as few overflow pages as possible, minimizing the overflow chain. If an overflow page becomes empty, overflow pages can be recycled for reuse in other buckets, though we never return them to the operating system. There is currently no provision to shrink a hash index, other than by rebuilding it with `REINDEX`. There is no provision for reducing the number of buckets, either.

Hash indexes may expand the number of bucket pages as the number of rows indexed grows. The hash key-to-bucket-number mapping is chosen so that the index can be incrementally expanded. When a new bucket is to be added to the index, exactly one existing bucket will need to be "split", with some of its tuples being transferred to the new bucket according to the updated key-to-bucket-number mapping.

The expansion occurs in the foreground, which could increase execution time for user inserts. Thus, hash indexes may not be suitable for tables with rapidly increasing number of rows.

## 64.2. Implementation

There are four kinds of pages in a hash index: the meta page (page zero), which contains statically allocated control information; primary bucket pages; overflow pages; and bitmap pages, which keep track of overflow pages that have been freed and are available for re-use. For addressing purposes, bitmap pages are regarded as a subset of the overflow pages.

Both scanning the index and inserting tuples require locating the bucket where a given tuple ought to be located. To do this, we need the bucket count, highmask, and lowmask from the metapage; however, it's undesirable for performance reasons to have to have to lock and pin the metapage for every such operation. Instead, we retain a cached copy of the metapage in each backend's relcache entry. This will produce the correct bucket mapping as long as the target bucket hasn't been split since the last cache refresh.

Primary bucket pages and overflow pages are allocated independently since any given index might need more or fewer overflow pages relative to its number of buckets. The hash code uses an interesting set of addressing rules to support a variable number of overflow pages while not having to move primary bucket pages around after they are created.

Each row in the table indexed is represented by a single index tuple in the hash index. Hash index tuples are stored in bucket pages, and if they exist, overflow pages. We speed up searches by keeping the index entries in any one index page sorted by hash code, thus allowing binary search to be used within an index page. Note however that there is *no* assumption about the relative ordering of hash codes across different index pages of a bucket.

The bucket splitting algorithms to expand the hash index are too complex to be worthy of mention here. The split algorithm is crash safe and can be restarted if not completed successfully.

---

# Chapter 65. Database Physical Storage

This chapter provides an overview of the physical storage format used by Postgres Pro databases.

## 65.1. Database File Layout

This section describes the storage format at the level of files and directories.

Traditionally, the configuration and data files used by a database cluster are stored together within the cluster's data directory, commonly referred to as `PGDATA` (after the name of the environment variable that can be used to define it). A common location for `PGDATA` is `/var/lib/pgpro/std-13/data`. Multiple clusters, managed by different server instances, can exist on the same machine.

The `PGDATA` directory contains several subdirectories and control files, as shown in [Table 65.1](#). In addition to these required items, the cluster configuration files `postgresql.conf`, `pg_hba.conf`, and `pg_ident.conf` are traditionally stored in `PGDATA`, although it is possible to place them elsewhere.

**Table 65.1. Contents of `PGDATA`**

Item	Description
<code>PG_VERSION</code>	A file containing the major version number of Postgres Pro
<code>base</code>	Subdirectory containing per-database subdirectories
<code>current_logfiles</code>	File recording the log file(s) currently written to by the logging collector
<code>global</code>	Subdirectory containing cluster-wide tables, such as <code>pg_database</code>
<code>pg_commit_ts</code>	Subdirectory containing transaction commit timestamp data
<code>pg_dynshmem</code>	Subdirectory containing files used by the dynamic shared memory subsystem
<code>pg_logical</code>	Subdirectory containing status data for logical decoding
<code>pg_multixact</code>	Subdirectory containing multitransaction status data (used for shared row locks)
<code>pg_notify</code>	Subdirectory containing LISTEN/NOTIFY status data
<code>pg_replslot</code>	Subdirectory containing replication slot data
<code>pg_serial</code>	Subdirectory containing information about committed serializable transactions
<code>pg_snapshots</code>	Subdirectory containing exported snapshots
<code>pg_stat</code>	Subdirectory containing permanent files for the statistics subsystem
<code>pg_stat_tmp</code>	Subdirectory containing temporary files for the statistics subsystem
<code>pg_subtrans</code>	Subdirectory containing subtransaction status data
<code>pg_tblspc</code>	Subdirectory containing symbolic links to tablespaces
<code>pg_twophase</code>	Subdirectory containing state files for prepared transactions

Item	Description
pg_wal	Subdirectory containing WAL (Write Ahead Log) files
pg_xact	Subdirectory containing transaction commit status data
postgresql.auto.conf	A file used for storing configuration parameters that are set by <code>ALTER SYSTEM</code>
postmaster.opts	A file recording the command-line options the server was last started with
postmaster.pid	A lock file recording the current postmaster process ID (PID), cluster data directory path, postmaster start timestamp, port number, Unix-domain socket directory path (could be empty), first valid listen_address (IP address or *, or empty if not listening on TCP), and shared memory segment ID (this file is not present after server shutdown)

For each database in the cluster there is a subdirectory within `PGDATA/base`, named after the database's OID in `pg_database`. This subdirectory is the default location for the database's files; in particular, its system catalogs are stored there.

Note that the following sections describe the behavior of the builtin heap [table access method](#), and the builtin [index access methods](#). Due to the extensible nature of Postgres Pro, other access methods might work differently.

Each table and index is stored in a separate file. For ordinary relations, these files are named after the table or index's *filenode* number, which can be found in `pg_class.relfilenode`. But for temporary relations, the file name is of the form `tBBB_FFF`, where *BBB* is the backend ID of the backend which created the file, and *FFF* is the filenode number. In either case, in addition to the main file (a/k/a main fork), each table and index has a *free space map* (see [Section 65.3](#)), which stores information about free space available in the relation. The free space map is stored in a file named with the filenode number plus the suffix `_fsm`. Tables also have a *visibility map*, stored in a fork with the suffix `_vm`, to track which pages are known to have no dead tuples. The visibility map is described further in [Section 65.4](#). Unlogged tables and indexes have a third fork, known as the initialization fork, which is stored in a fork with the suffix `_init` (see [Section 65.5](#)).

### Caution

Note that while a table's filenode often matches its OID, this is *not* necessarily the case; some operations, like `TRUNCATE`, `REINDEX`, `CLUSTER` and some forms of `ALTER TABLE`, can change the filenode while preserving the OID. Avoid assuming that filenode and table OID are the same. Also, for certain system catalogs including `pg_class` itself, `pg_class.relfilenode` contains zero. The actual filenode number of these catalogs is stored in a lower-level data structure, and can be obtained using the `pg_relation_filenode()` function.

When a table or index exceeds 1 GB, it is divided into gigabyte-sized *segments*. The first segment's file name is the same as the filenode; subsequent segments are named `filenode.1`, `filenode.2`, etc. This arrangement avoids problems on platforms that have file size limitations. (Actually, 1 GB is just the default segment size. The segment size can be adjusted using the configuration option `--with-segsize` when building Postgres Pro.) In principle, free space map and visibility map forks could require multiple segments as well, though this is unlikely to happen in practice.

A table that has columns with potentially large entries will have an associated *TOAST* table, which is used for out-of-line storage of field values that are too large to keep in the table rows proper.

`pg_class.reltoastrelid` links from a table to its TOAST table, if any. See [Section 65.2](#) for more information.

The contents of tables and indexes are discussed further in [Section 65.6](#).

Tablespaces make the scenario more complicated. Each user-defined tablespace has a symbolic link inside the `PGDATA/pg_tblspc` directory, which points to the physical tablespace directory (i.e., the location specified in the tablespace's `CREATE TABLESPACE` command). This symbolic link is named after the tablespace's OID. Inside the physical tablespace directory there is a subdirectory with a name that depends on the Postgres Pro server version, such as `PG_9.0_201008051`. (The reason for using this subdirectory is so that successive versions of the database can use the same `CREATE TABLESPACE` location value without conflicts.) Within the version-specific subdirectory, there is a subdirectory for each database that has elements in the tablespace, named after the database's OID. Tables and indexes are stored within that directory, using the filenode naming scheme. The `pg_default` tablespace is not accessed through `pg_tblspc`, but corresponds to `PGDATA/base`. Similarly, the `pg_global` tablespace is not accessed through `pg_tblspc`, but corresponds to `PGDATA/global`.

The `pg_relation_filepath()` function shows the entire path (relative to `PGDATA`) of any relation. It is often useful as a substitute for remembering many of the above rules. But keep in mind that this function just gives the name of the first segment of the main fork of the relation — you may need to append a segment number and/or `_fsm`, `_vm`, or `_init` to find all the files associated with the relation.

Temporary files (for operations such as sorting more data than can fit in memory) are created within `PGDATA/base/pgsql_tmp`, or within a `pgsql_tmp` subdirectory of a tablespace directory if a tablespace other than `pg_default` is specified for them. The name of a temporary file has the form `pgsql_tmpPPP.NNN`, where `PPP` is the PID of the owning backend and `NNN` distinguishes different temporary files of that backend.

## 65.2. TOAST

This section provides an overview of TOAST (The Oversized-Attribute Storage Technique).

Postgres Pro uses a fixed page size (commonly 8 kB), and does not allow tuples to span multiple pages. Therefore, it is not possible to store very large field values directly. To overcome this limitation, large field values are compressed and/or broken up into multiple physical rows. This happens transparently to the user, with only small impact on most of the backend code. The technique is affectionately known as TOAST (or “the best thing since sliced bread”). The TOAST infrastructure is also used to improve handling of large data values in-memory.

Only certain data types support TOAST — there is no need to impose the overhead on data types that cannot produce large field values. To support TOAST, a data type must have a variable-length (*varlena*) representation, in which, ordinarily, the first four-byte word of any stored value contains the total length of the value in bytes (including itself). TOAST does not constrain the rest of the data type's representation. The special representations collectively called *TOASTed values* work by modifying or reinterpreting this initial length word. Therefore, the C-level functions supporting a TOAST-able data type must be careful about how they handle potentially TOASTed input values: an input might not actually consist of a four-byte length word and contents until after it's been *detoasted*. (This is normally done by invoking `PG_DETOAST_DATUM` before doing anything with an input value, but in some cases more efficient approaches are possible. See [Section 35.13.1](#) for more detail.)

TOAST usurps two bits of the *varlena* length word (the high-order bits on big-endian machines, the low-order bits on little-endian machines), thereby limiting the logical size of any value of a TOAST-able data type to 1 GB ( $2^{30}$  - 1 bytes). When both bits are zero, the value is an ordinary un-TOASTed value of the data type, and the remaining bits of the length word give the total datum size (including length word) in bytes. When the highest-order or lowest-order bit is set, the value has only a single-byte header instead of the normal four-byte header, and the remaining bits of that byte give the total datum size (including length byte) in bytes. This alternative supports space-efficient storage of values shorter than 127 bytes, while still allowing the data type to grow to 1 GB at need. Values with single-byte headers aren't aligned on any

particular boundary, whereas values with four-byte headers are aligned on at least a four-byte boundary; this omission of alignment padding provides additional space savings that is significant compared to short values. As a special case, if the remaining bits of a single-byte header are all zero (which would be impossible for a self-inclusive length), the value is a pointer to out-of-line data, with several possible alternatives as described below. The type and size of such a *TOAST pointer* are determined by a code stored in the second byte of the datum. Lastly, when the highest-order or lowest-order bit is clear but the adjacent bit is set, the content of the datum has been compressed and must be decompressed before use. In this case the remaining bits of the four-byte length word give the total size of the compressed datum, not the original data. Note that compression is also possible for out-of-line data but the varlena header does not tell whether it has occurred — the content of the TOAST pointer tells that, instead.

As mentioned, there are multiple types of TOAST pointer datums. The oldest and most common type is a pointer to out-of-line data stored in a *TOAST table* that is separate from, but associated with, the table containing the TOAST pointer datum itself. These *on-disk* pointer datums are created by the TOAST management code when a tuple to be stored on disk is too large to be stored as-is. Further details appear in [Section 65.2.1](#). Alternatively, a TOAST pointer datum can contain a pointer to out-of-line data that appears elsewhere in memory. Such datums are necessarily short-lived, and will never appear on-disk, but they are very useful for avoiding copying and redundant processing of large data values. Further details appear in [Section 65.2.2](#).

The compression technique used for either in-line or out-of-line compressed data is a fairly simple and very fast member of the LZ family of compression techniques.

### 65.2.1. Out-of-Line, On-Disk TOAST Storage

If any of the columns of a table are TOAST-able, the table will have an associated TOAST table, whose OID is stored in the table's `pg_class.reltoastrelid` entry. On-disk TOASTed values are kept in the TOAST table, as described in more detail below.

Out-of-line values are divided (after compression if used) into chunks of at most `TOAST_MAX_CHUNK_SIZE` bytes (by default this value is chosen so that four chunk rows will fit on a page, making it about 2000 bytes). Each chunk is stored as a separate row in the TOAST table belonging to the owning table. Every TOAST table has the columns `chunk_id` (an OID identifying the particular TOASTed value), `chunk_seq` (a sequence number for the chunk within its value), and `chunk_data` (the actual data of the chunk). A unique index on `chunk_id` and `chunk_seq` provides fast retrieval of the values. A pointer datum representing an out-of-line on-disk TOASTed value therefore needs to store the OID of the TOAST table in which to look and the OID of the specific value (its `chunk_id`). For convenience, pointer datums also store the logical datum size (original uncompressed data length) and physical stored size (different if compression was applied). Allowing for the varlena header bytes, the total size of an on-disk TOAST pointer datum is therefore 18 bytes regardless of the actual size of the represented value.

The TOAST management code is triggered only when a row value to be stored in a table is wider than `TOAST_TUPLE_THRESHOLD` bytes (normally 2 kB). The TOAST code will compress and/or move field values out-of-line until the row value is shorter than `TOAST_TUPLE_TARGET` bytes (also normally 2 kB, adjustable) or no more gains can be had. During an UPDATE operation, values of unchanged fields are normally preserved as-is; so an UPDATE of a row with out-of-line values incurs no TOAST costs if none of the out-of-line values change.

The TOAST management code recognizes four different strategies for storing TOAST-able columns on disk:

- `PLAIN` prevents either compression or out-of-line storage; furthermore it disables use of single-byte headers for varlena types. This is the only possible strategy for columns of non-TOAST-able data types.
- `EXTENDED` allows both compression and out-of-line storage. This is the default for most TOAST-able data types. Compression will be attempted first, then out-of-line storage if the row is still too big.
- `EXTERNAL` allows out-of-line storage but not compression. Use of `EXTERNAL` will make substring operations on wide `text` and `bytea` columns faster (at the penalty of increased storage space)

because these operations are optimized to fetch only the required parts of the out-of-line value when it is not compressed.

- `MAIN` allows compression but not out-of-line storage. (Actually, out-of-line storage will still be performed for such columns, but only as a last resort when there is no other way to make the row small enough to fit on a page.)

Each TOAST-able data type specifies a default strategy for columns of that data type, but the strategy for a given table column can be altered with `ALTER TABLE ... SET STORAGE`.

`TOAST_TUPLE_TARGET` can be adjusted for each table using `ALTER TABLE ... SET (toast_tuple_target = N)`

This scheme has a number of advantages compared to a more straightforward approach such as allowing row values to span pages. Assuming that queries are usually qualified by comparisons against relatively small key values, most of the work of the executor will be done using the main row entry. The big values of TOASTed attributes will only be pulled out (if selected at all) at the time the result set is sent to the client. Thus, the main table is much smaller and more of its rows fit in the shared buffer cache than would be the case without any out-of-line storage. Sort sets shrink also, and sorts will more often be done entirely in memory. A little test showed that a table containing typical HTML pages and their URLs was stored in about half of the raw data size including the TOAST table, and that the main table contained only about 10% of the entire data (the URLs and some small HTML pages). There was no run time difference compared to an un-TOASTed comparison table, in which all the HTML pages were cut down to 7 kB to fit.

## 65.2.2. Out-of-Line, In-Memory TOAST Storage

TOAST pointers can point to data that is not on disk, but is elsewhere in the memory of the current server process. Such pointers obviously cannot be long-lived, but they are nonetheless useful. There are currently two sub-cases: pointers to *indirect* data and pointers to *expanded* data.

Indirect TOAST pointers simply point at a non-indirect varlena value stored somewhere in memory. This case was originally created merely as a proof of concept, but it is currently used during logical decoding to avoid possibly having to create physical tuples exceeding 1 GB (as pulling all out-of-line field values into the tuple might do). The case is of limited use since the creator of the pointer datum is entirely responsible that the referenced data survives for as long as the pointer could exist, and there is no infrastructure to help with this.

Expanded TOAST pointers are useful for complex data types whose on-disk representation is not especially suited for computational purposes. As an example, the standard varlena representation of a Postgres Pro array includes dimensionality information, a nulls bitmap if there are any null elements, then the values of all the elements in order. When the element type itself is variable-length, the only way to find the *N*th element is to scan through all the preceding elements. This representation is appropriate for on-disk storage because of its compactness, but for computations with the array it's much nicer to have an "expanded" or "deconstructed" representation in which all the element starting locations have been identified. The TOAST pointer mechanism supports this need by allowing a pass-by-reference Datum to point to either a standard varlena value (the on-disk representation) or a TOAST pointer that points to an expanded representation somewhere in memory. The details of this expanded representation are up to the data type, though it must have a standard header and meet the other API requirements given in `src/include/utils/expandeddatum.h`. C-level functions working with the data type can choose to handle either representation. Functions that do not know about the expanded representation, but simply apply `PG_DETOAST_DATUM` to their inputs, will automatically receive the traditional varlena representation; so support for an expanded representation can be introduced incrementally, one function at a time.

TOAST pointers to expanded values are further broken down into *read-write* and *read-only* pointers. The pointed-to representation is the same either way, but a function that receives a read-write pointer is allowed to modify the referenced value in-place, whereas one that receives a read-only pointer must not; it must first create a copy if it wants to make a modified version of the value. This distinction and some associated conventions make it possible to avoid unnecessary copying of expanded values during query execution.

For all types of in-memory TOAST pointer, the TOAST management code ensures that no such pointer datum can accidentally get stored on disk. In-memory TOAST pointers are automatically expanded to normal in-line varlena values before storage — and then possibly converted to on-disk TOAST pointers, if the containing tuple would otherwise be too big.

## 65.3. Free Space Map

Each heap and index relation, except for hash indexes, has a Free Space Map (FSM) to keep track of available space in the relation. It's stored alongside the main relation data in a separate relation fork, named after the filenode number of the relation, plus a `_fsm` suffix. For example, if the filenode of a relation is 12345, the FSM is stored in a file called `12345_fsm`, in the same directory as the main relation file.

The Free Space Map is organized as a tree of FSM pages. The bottom level FSM pages store the free space available on each heap (or index) page, using one byte to represent each such page. The upper levels aggregate information from the lower levels.

Within each FSM page is a binary tree, stored in an array with one byte per node. Each leaf node represents a heap page, or a lower level FSM page. In each non-leaf node, the higher of its children's values is stored. The maximum value in the leaf nodes is therefore stored at the root.

The `pg_freespacemap` module can be used to examine the information stored in free space maps.

## 65.4. Visibility Map

Each heap relation has a Visibility Map (VM) to keep track of which pages contain only tuples that are known to be visible to all active transactions; it also keeps track of which pages contain only frozen tuples. It's stored alongside the main relation data in a separate relation fork, named after the filenode number of the relation, plus a `_vm` suffix. For example, if the filenode of a relation is 12345, the VM is stored in a file called `12345_vm`, in the same directory as the main relation file. Note that indexes do not have VMs.

The visibility map stores two bits per heap page. The first bit, if set, indicates that the page is all-visible, or in other words that the page does not contain any tuples that need to be vacuumed. This information can also be used by *index-only scans* to answer queries using only the index tuple. The second bit, if set, means that all tuples on the page have been frozen. That means that even an anti-wraparound vacuum need not revisit the page.

The map is conservative in the sense that we make sure that whenever a bit is set, we know the condition is true, but if a bit is not set, it might or might not be true. Visibility map bits are only set by vacuum, but are cleared by any data-modifying operations on a page.

The `pg_visibility` module can be used to examine the information stored in the visibility map.

## 65.5. The Initialization Fork

Each unlogged table, and each index on an unlogged table, has an initialization fork. The initialization fork is an empty table or index of the appropriate type. When an unlogged table must be reset to empty due to a crash, the initialization fork is copied over the main fork, and any other forks are erased (they will be recreated automatically as needed).

## 65.6. Database Page Layout

This section provides an overview of the page format used within Postgres Pro tables and indexes.<sup>1</sup> Sequences and TOAST tables are formatted just like a regular table.

---

<sup>1</sup> Actually, use of this page format is not required for either table or index access methods. The `heap` table access method always uses this format. All the existing index methods also use the basic format, but the data kept on index metapages usually doesn't follow the item layout rules.

In the following explanation, a *byte* is assumed to contain 8 bits. In addition, the term *item* refers to an individual data value that is stored on a page. In a table, an item is a row; in an index, an item is an index entry.

Every table and index is stored as an array of *pages* of a fixed size (usually 8 kB, although a different page size can be selected when compiling the server). In a table, all the pages are logically equivalent, so a particular item (row) can be stored in any page. In indexes, the first page is generally reserved as a *metapage* holding control information, and there can be different types of pages within the index, depending on the index access method.

Table 65.2 shows the overall layout of a page. There are five parts to each page.

**Table 65.2. Overall Page Layout**

Item	Description
PageHeaderData	24 bytes long. Contains general information about the page, including free space pointers.
ItemIdData	Array of item identifiers pointing to the actual items. Each entry is an (offset,length) pair. 4 bytes per item.
Free space	The unallocated space. New item identifiers are allocated from the start of this area, new items from the end.
Items	The actual items themselves.
Special space	Index access method specific data. Different methods store different data. Empty in ordinary tables.

The first 24 bytes of each page consists of a page header (*PageHeaderData*). Its format is detailed in Table 65.3. The first field tracks the most recent WAL entry related to this page. The second field contains the page checksum if [data checksums](#) are enabled. Next is a 2-byte field containing flag bits. This is followed by three 2-byte integer fields (*pd\_lower*, *pd\_upper*, and *pd\_special*). These contain byte offsets from the page start to the start of unallocated space, to the end of unallocated space, and to the start of the special space. The next 2 bytes of the page header, *pd\_pagesize\_version*, store both the page size and a version indicator. Beginning with PostgreSQL 8.3 the version number is 4; PostgreSQL 8.1 and 8.2 used version number 3; PostgreSQL 8.0 used version number 2; PostgreSQL 7.3 and 7.4 used version number 1; prior releases used version number 0. (The basic page layout and header format has not changed in most of these versions, but the layout of heap row headers has.) The page size is basically only present as a cross-check; there is no support for having more than one page size in an installation. The last field is a hint that shows whether pruning the page is likely to be profitable: it tracks the oldest un-pruned XMAX on the page.

**Table 65.3. PageHeaderData Layout**

Field	Type	Length	Description
<i>pd_lsn</i>	PageXLogRecPtr	8 bytes	LSN: next byte after last byte of WAL record for last change to this page
<i>pd_checksum</i>	uint16	2 bytes	Page checksum
<i>pd_flags</i>	uint16	2 bytes	Flag bits
<i>pd_lower</i>	LocationIndex	2 bytes	Offset to start of free space
<i>pd_upper</i>	LocationIndex	2 bytes	Offset to end of free space
<i>pd_special</i>	LocationIndex	2 bytes	Offset to start of special space

Field	Type	Length	Description
pd_pagesize_version	uint16	2 bytes	Page size and layout version number information
pd_prune_xid	TransactionId	4 bytes	Oldest unpruned XMAX on page, or zero if none

Following the page header are item identifiers (`ItemIdData`), each requiring four bytes. An item identifier contains a byte-offset to the start of an item, its length in bytes, and a few attribute bits which affect its interpretation. New item identifiers are allocated as needed from the beginning of the unallocated space. The number of item identifiers present can be determined by looking at `pd_lower`, which is increased to allocate a new identifier. Because an item identifier is never moved until it is freed, its index can be used on a long-term basis to reference an item, even when the item itself is moved around on the page to compact free space. In fact, every pointer to an item (`ItemPointer`, also known as `CTID`) created by Postgres Pro consists of a page number and the index of an item identifier.

The items themselves are stored in space allocated backwards from the end of unallocated space. The exact structure varies depending on what the table is to contain. Tables and sequences both use a structure named `HeapTupleHeaderData`, described below.

The final section is the “special section” which can contain anything the access method wishes to store. For example, b-tree indexes store links to the page's left and right siblings, as well as some other data relevant to the index structure. Ordinary tables do not use a special section at all (indicated by setting `pd_special` to equal the page size).

Figure 65.1 illustrates how these parts are laid out in a page.

**Figure 65.1. Page Layout**

### 65.6.1. Table Row Layout

All table rows are structured in the same way. There is a fixed-size header (occupying 23 bytes on most machines), followed by an optional null bitmap, an optional object ID field, and the user data. The header is detailed in Table 65.4. The actual user data (columns of the row) begins at the offset indicated by `t_hoff`, which must always be a multiple of the `MAXALIGN` distance for the platform. The null bitmap is only present if the `HEAP_HASNULL` bit is set in `t_infomask`. If it is present it begins just after the fixed header and occupies enough bytes to have one bit per data column (that is, the number of bits that equals the attribute count in `t_infomask2`). In this list of bits, a 1 bit indicates not-null, a 0 bit is a null. When the bitmap is not present, all columns are assumed not-null. The object ID is only present if the `HEAP_HASOID_OLD` bit is set in `t_infomask`. If present, it appears just before the `t_hoff` boundary. Any padding needed to make `t_hoff` a `MAXALIGN` multiple will appear between the null bitmap and the object ID. (This in turn ensures that the object ID is suitably aligned.)

**Table 65.4. HeapTupleHeaderData Layout**

Field	Type	Length	Description
t_xmin	TransactionId	4 bytes	insert XID stamp
t_xmax	TransactionId	4 bytes	delete XID stamp
t_cid	CommandId	4 bytes	insert and/or delete CID stamp (overlays with t_xvac)
t_xvac	TransactionId	4 bytes	XID for VACUUM operation moving a row version
t_ctid	ItemPointerData	6 bytes	current TID of this or newer row version
t_infomask2	uint16	2 bytes	number of attributes, plus various flag bits
t_infomask	uint16	2 bytes	various flag bits
t_hoff	uint8	1 byte	offset to user data

Interpreting the actual data can only be done with information obtained from other tables, mostly `pg_attribute`. The key values needed to identify field locations are `attlen` and `attalign`. There is no way to directly get a particular attribute, except when there are only fixed width fields and no null values. All this trickery is wrapped up in the functions `heap_getattr`, `fastgetattr` and `heap_getsysattr`.

To read the data you need to examine each attribute in turn. First check whether the field is NULL according to the null bitmap. If it is, go to the next. Then make sure you have the right alignment. If the field is a fixed width field, then all the bytes are simply placed. If it's a variable length field (`attlen = -1`) then it's a bit more complicated. All variable-length data types share the common header structure `struct varlena`, which includes the total length of the stored value and some flag bits. Depending on the flags, the data can be either inline or in a TOAST table; it might be compressed, too (see [Section 65.2](#)).

---

# Chapter 66. How the Planner Uses Statistics

This chapter builds on the material covered in [Section 14.1](#) and [Section 14.2](#) to show some additional details about how the planner uses the system statistics to estimate the number of rows each part of a query might return. This is a significant part of the planning process, providing much of the raw material for cost calculation.

The intent of this chapter is not to document the code in detail, but to present an overview of how it works. This will perhaps ease the learning curve for someone who subsequently wishes to read the code.

## 66.1. Row Estimation Examples

The examples shown below use tables in the Postgres Pro regression test database. The outputs shown are taken from version 8.3. The behavior of earlier (or later) versions might vary. Note also that since `ANALYZE` uses random sampling while producing statistics, the results will change slightly after any new `ANALYZE`.

Let's start with a very simple query:

```
EXPLAIN SELECT * FROM tenk1;
```

QUERY PLAN

```
-----  
Seq Scan on tenk1 (cost=0.00..458.00 rows=10000 width=244)
```

How the planner determines the cardinality of `tenk1` is covered in [Section 14.2](#), but is repeated here for completeness. The number of pages and rows is looked up in `pg_class`:

```
SELECT relpages, reltuples FROM pg_class WHERE relname = 'tenk1';
```

```
relpages | reltuples  
-----+-----  
    358 |    10000
```

These numbers are current as of the last `VACUUM` or `ANALYZE` on the table. The planner then fetches the actual current number of pages in the table (this is a cheap operation, not requiring a table scan). If that is different from `relpages` then `reltuples` is scaled accordingly to arrive at a current number-of-rows estimate. In the example above, the value of `relpages` is up-to-date so the rows estimate is the same as `reltuples`.

Let's move on to an example with a range condition in its `WHERE` clause:

```
EXPLAIN SELECT * FROM tenk1 WHERE unique1 < 1000;
```

QUERY PLAN

```
-----  
Bitmap Heap Scan on tenk1 (cost=24.06..394.64 rows=1007 width=244)  
  Recheck Cond: (unique1 < 1000)  
    -> Bitmap Index Scan on tenk1_unique1 (cost=0.00..23.80 rows=1007 width=0)  
        Index Cond: (unique1 < 1000)
```

The planner examines the `WHERE` clause condition and looks up the selectivity function for the operator `<` in `pg_operator`. This is held in the column `oprrest`, and the entry in this case is `scalarlttsel`. The `scalarlttsel` function retrieves the histogram for `unique1` from `pg_statistic`. For manual queries it is more convenient to look in the simpler `pg_stats` view:

```
SELECT histogram_bounds FROM pg_stats  
WHERE tablename='tenk1' AND attname='unique1';
```

histogram\_bounds

```
-----  
{0, 993, 1997, 3050, 4040, 5036, 5957, 7057, 8029, 9016, 9995}
```

Next the fraction of the histogram occupied by “< 1000” is worked out. This is the selectivity. The histogram divides the range into equal frequency buckets, so all we have to do is locate the bucket that our value is in and count *part* of it and *all* of the ones before. The value 1000 is clearly in the second bucket (993–1997). Assuming a linear distribution of values inside each bucket, we can calculate the selectivity as:

```
selectivity = (1 + (1000 - bucket[2].min)/(bucket[2].max - bucket[2].min))/num_buckets
            = (1 + (1000 - 993)/(1997 - 993))/10
            = 0.100697
```

that is, one whole bucket plus a linear fraction of the second, divided by the number of buckets. The estimated number of rows can now be calculated as the product of the selectivity and the cardinality of `tenk1`:

```
rows = rel_cardinality * selectivity
      = 10000 * 0.100697
      = 1007 (rounding off)
```

Next let's consider an example with an equality condition in its `WHERE` clause:

```
EXPLAIN SELECT * FROM tenk1 WHERE stringu1 = 'CRAAAA';
```

QUERY PLAN

```
-----
Seq Scan on tenk1 (cost=0.00..483.00 rows=30 width=244)
  Filter: (stringu1 = 'CRAAAA'::name)
```

Again the planner examines the `WHERE` clause condition and looks up the selectivity function for `=`, which is `eqsel`. For equality estimation the histogram is not useful; instead the list of *most common values* (MCVs) is used to determine the selectivity. Let's have a look at the MCVs, with some additional columns that will be useful later:

```
SELECT null_frac, n_distinct, most_common_vals, most_common_freqs FROM pg_stats
WHERE tablename='tenk1' AND attname='stringu1';
```

```
null_frac          | 0
n_distinct         | 676
most_common_vals   | {EJAAAA, BBAAAA, CRAAAA, FCAAAA, FEAAAA, GSAAAA,
JOAAAA, MCAAAA, NAAAAA, WGAAAA}
most_common_freqs  | {0.00333333, 0.003, 0.003, 0.003, 0.003, 0.003, 0.003, 0.003, 0.003, 0.003}
```

Since `CRAAAA` appears in the list of MCVs, the selectivity is merely the corresponding entry in the list of most common frequencies (MCFs):

```
selectivity = mcf[3]
            = 0.003
```

As before, the estimated number of rows is just the product of this with the cardinality of `tenk1`:

```
rows = 10000 * 0.003
      = 30
```

Now consider the same query, but with a constant that is not in the MCV list:

```
EXPLAIN SELECT * FROM tenk1 WHERE stringu1 = 'xxx';
```

QUERY PLAN

```
-----
Seq Scan on tenk1 (cost=0.00..483.00 rows=15 width=244)
  Filter: (stringu1 = 'xxx'::name)
```

This is quite a different problem: how to estimate the selectivity when the value is *not* in the MCV list. The approach is to use the fact that the value is not in the list, combined with the knowledge of the frequencies for all of the MCVs:

```
selectivity = (1 - sum(mvf))/(num_distinct - num_mcv)
            = (1 - (0.00333333 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003 +
                    0.003 + 0.003 + 0.003 + 0.003))/(676 - 10)
            = 0.0014559
```

That is, add up all the frequencies for the MCVs and subtract them from one, then divide by the number of *other* distinct values. This amounts to assuming that the fraction of the column that is not any of the MCVs is evenly distributed among all the other distinct values. Notice that there are no null values so we don't have to worry about those (otherwise we'd subtract the null fraction from the numerator as well). The estimated number of rows is then calculated as usual:

```
rows = 10000 * 0.0014559
      = 15 (rounding off)
```

The previous example with `unique1 < 1000` was an oversimplification of what `scalarltsel` really does; now that we have seen an example of the use of MCVs, we can fill in some more detail. The example was correct as far as it went, because since `unique1` is a unique column it has no MCVs (obviously, no value is any more common than any other value). For a non-unique column, there will normally be both a histogram and an MCV list, and *the histogram does not include the portion of the column population represented by the MCVs*. We do things this way because it allows more precise estimation. In this situation `scalarltsel` directly applies the condition (e.g., “< 1000”) to each value of the MCV list, and adds up the frequencies of the MCVs for which the condition is true. This gives an exact estimate of the selectivity within the portion of the table that is MCVs. The histogram is then used in the same way as above to estimate the selectivity in the portion of the table that is not MCVs, and then the two numbers are combined to estimate the overall selectivity. For example, consider

```
EXPLAIN SELECT * FROM tenk1 WHERE stringu1 < 'IAAAAA';
```

QUERY PLAN

```
-----
Seq Scan on tenk1 (cost=0.00..483.00 rows=3077 width=244)
  Filter: (stringu1 < 'IAAAAA'::name)
```

We already saw the MCV information for `stringu1`, and here is its histogram:

```
SELECT histogram_bounds FROM pg_stats
WHERE tablename='tenk1' AND attname='stringu1';
```

histogram\_bounds

```
-----
{AAAAAA, CQAAAA, FRAAAA, IBAAAA, KRAAAA, NFAAAA, PSAAAA, SGAAAA, VAAAAA, XLAAAA, ZZAAAA}
```

Checking the MCV list, we find that the condition `stringu1 < 'IAAAAA'` is satisfied by the first six entries and not the last four, so the selectivity within the MCV part of the population is

```
selectivity = sum(relevant mvfs)
            = 0.00333333 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003
            = 0.01833333
```

Summing all the MCFs also tells us that the total fraction of the population represented by MCVs is 0.03033333, and therefore the fraction represented by the histogram is 0.96966667 (again, there are no nulls, else we'd have to exclude them here). We can see that the value `IAAAAA` falls nearly at the end of the third histogram bucket. Using some rather cheesy assumptions about the frequency of different characters, the planner arrives at the estimate 0.298387 for the portion of the histogram population that is less than `IAAAAA`. We then combine the estimates for the MCV and non-MCV populations:

```
selectivity = mcv_selectivity + histogram_selectivity * histogram_fraction
            = 0.01833333 + 0.298387 * 0.96966667
            = 0.307669
```

```
rows = 10000 * 0.307669
      = 3077 (rounding off)
```

In this particular example, the correction from the MCV list is fairly small, because the column distribution is actually quite flat (the statistics showing these particular values as being more common than others are mostly due to sampling error). In a more typical case where some values are significantly more common than others, this complicated process gives a useful improvement in accuracy because the selectivity for the most common values is found exactly.

Now let's consider a case with more than one condition in the WHERE clause:

```
EXPLAIN SELECT * FROM tenk1 WHERE unique1 < 1000 AND stringu1 = 'xxx';
```

QUERY PLAN

```
-----
Bitmap Heap Scan on tenk1 (cost=23.80..396.91 rows=1 width=244)
  Recheck Cond: (unique1 < 1000)
  Filter: (stringu1 = 'xxx'::name)
-> Bitmap Index Scan on tenk1_unique1 (cost=0.00..23.80 rows=1007 width=0)
    Index Cond: (unique1 < 1000)
```

The planner assumes that the two conditions are independent, so that the individual selectivities of the clauses can be multiplied together:

```
selectivity = selectivity(unique1 < 1000) * selectivity(stringu1 = 'xxx')
              = 0.100697 * 0.0014559
              = 0.0001466
```

```
rows        = 10000 * 0.0001466
              = 1 (rounding off)
```

Notice that the number of rows estimated to be returned from the bitmap index scan reflects only the condition used with the index; this is important since it affects the cost estimate for the subsequent heap fetches.

Finally we will examine a query that involves a join:

```
EXPLAIN SELECT * FROM tenk1 t1, tenk2 t2
WHERE t1.unique1 < 50 AND t1.unique2 = t2.unique2;
```

QUERY PLAN

```
-----
Nested Loop (cost=4.64..456.23 rows=50 width=488)
-> Bitmap Heap Scan on tenk1 t1 (cost=4.64..142.17 rows=50 width=244)
    Recheck Cond: (unique1 < 50)
-> Bitmap Index Scan on tenk1_unique1 (cost=0.00..4.63 rows=50 width=0)
    Index Cond: (unique1 < 50)
-> Index Scan using tenk2_unique2 on tenk2 t2 (cost=0.00..6.27 rows=1 width=244)
    Index Cond: (unique2 = t1.unique2)
```

The restriction on tenk1, unique1 < 50, is evaluated before the nested-loop join. This is handled analogously to the previous range example. This time the value 50 falls into the first bucket of the unique1 histogram:

```
selectivity = (0 + (50 - bucket[1].min)/(bucket[1].max - bucket[1].min))/num_buckets
              = (0 + (50 - 0)/(993 - 0))/10
              = 0.005035
```

```
rows        = 10000 * 0.005035
              = 50 (rounding off)
```

The restriction for the join is t2.unique2 = t1.unique2. The operator is just our familiar =, however the selectivity function is obtained from the oprjoin column of pg\_operator, and is eqjoinsel. eqjoinsel looks up the statistical information for both tenk2 and tenk1:

```
SELECT tablename, null_frac, n_distinct, most_common_vals FROM pg_stats
```

```
WHERE tablename IN ('tenk1', 'tenk2') AND attname='unique2';
```

tablename	null_frac	n_distinct	most_common_vals
tenk1	0	-1	
tenk2	0	-1	

In this case there is no MCV information for `unique2` because all the values appear to be unique, so we use an algorithm that relies only on the number of distinct values for both relations together with their null fractions:

```
selectivity = (1 - null_frac1) * (1 - null_frac2) * min(1/num_distinct1, 1/
num_distinct2)
             = (1 - 0) * (1 - 0) / max(10000, 10000)
             = 0.0001
```

This is, subtract the null fraction from one for each of the relations, and divide by the maximum of the numbers of distinct values. The number of rows that the join is likely to emit is calculated as the cardinality of the Cartesian product of the two inputs, multiplied by the selectivity:

```
rows = (outer_cardinality * inner_cardinality) * selectivity
      = (50 * 10000) * 0.0001
      = 50
```

Had there been MCV lists for the two columns, `eqjoinsel` would have used direct comparison of the MCV lists to determine the join selectivity within the part of the column populations represented by the MCVs. The estimate for the remainder of the populations follows the same approach shown here.

Notice that we showed `inner_cardinality` as 10000, that is, the unmodified size of `tenk2`. It might appear from inspection of the `EXPLAIN` output that the estimate of join rows comes from  $50 * 1$ , that is, the number of outer rows times the estimated number of rows obtained by each inner index scan on `tenk2`. But this is not the case: the join relation size is estimated before any particular join plan has been considered. If everything is working well then the two ways of estimating the join size will produce about the same answer, but due to round-off error and other factors they sometimes diverge significantly.

## 66.2. Multivariate Statistics Examples

### 66.2.1. Functional Dependencies

Multivariate correlation can be demonstrated with a very simple data set — a table with two columns, both containing the same values:

```
CREATE TABLE t (a INT, b INT);
INSERT INTO t SELECT i % 100, i % 100 FROM generate_series(1, 10000) s(i);
ANALYZE t;
```

As explained in [Section 14.2](#), the planner can determine cardinality of `t` using the number of pages and rows obtained from `pg_class`:

```
SELECT relpages, reltuples FROM pg_class WHERE relname = 't';
```

relpages	reltuples
45	10000

The data distribution is very simple; there are only 100 distinct values in each column, uniformly distributed.

The following example shows the result of estimating a `WHERE` condition on the `a` column:

```
EXPLAIN (ANALYZE, TIMING OFF) SELECT * FROM t WHERE a = 1;
QUERY PLAN
```

```
Seq Scan on t (cost=0.00..170.00 rows=100 width=8) (actual rows=100 loops=1)
  Filter: (a = 1)
  Rows Removed by Filter: 9900
```

The planner examines the condition and determines the selectivity of this clause to be 1%. By comparing this estimate and the actual number of rows, we see that the estimate is very accurate (in fact exact, as the table is very small). Changing the `WHERE` condition to use the `b` column, an identical plan is generated. But observe what happens if we apply the same condition on both columns, combining them with `AND`:

```
EXPLAIN (ANALYZE, TIMING OFF) SELECT * FROM t WHERE a = 1 AND b = 1;
          QUERY PLAN
```

```
-----
Seq Scan on t (cost=0.00..195.00 rows=1 width=8) (actual rows=100 loops=1)
  Filter: ((a = 1) AND (b = 1))
  Rows Removed by Filter: 9900
```

The planner estimates the selectivity for each condition individually, arriving at the same 1% estimates as above. Then it assumes that the conditions are independent, and so it multiplies their selectivities, producing a final selectivity estimate of just 0.01%. This is a significant underestimate, as the actual number of rows matching the conditions (100) is two orders of magnitude higher.

This problem can be fixed by creating a statistics object that directs `ANALYZE` to calculate functional-dependency multivariate statistics on the two columns:

```
CREATE STATISTICS stts (dependencies) ON a, b FROM t;
ANALYZE t;
EXPLAIN (ANALYZE, TIMING OFF) SELECT * FROM t WHERE a = 1 AND b = 1;
          QUERY PLAN
```

```
-----
Seq Scan on t (cost=0.00..195.00 rows=100 width=8) (actual rows=100 loops=1)
  Filter: ((a = 1) AND (b = 1))
  Rows Removed by Filter: 9900
```

## 66.2.2. Multivariate N-Distinct Counts

A similar problem occurs with estimation of the cardinality of sets of multiple columns, such as the number of groups that would be generated by a `GROUP BY` clause. When `GROUP BY` lists a single column, the `n`-distinct estimate (which is visible as the estimated number of rows returned by the `HashAggregate` node) is very accurate:

```
EXPLAIN (ANALYZE, TIMING OFF) SELECT COUNT(*) FROM t GROUP BY a;
          QUERY PLAN
```

```
-----
HashAggregate (cost=195.00..196.00 rows=100 width=12) (actual rows=100 loops=1)
  Group Key: a
  -> Seq Scan on t (cost=0.00..145.00 rows=10000 width=4) (actual rows=10000
  loops=1)
```

But without multivariate statistics, the estimate for the number of groups in a query with two columns in `GROUP BY`, as in the following example, is off by an order of magnitude:

```
EXPLAIN (ANALYZE, TIMING OFF) SELECT COUNT(*) FROM t GROUP BY a, b;
          QUERY PLAN
```

```
-----
HashAggregate (cost=220.00..230.00 rows=1000 width=16) (actual rows=100 loops=1)
  Group Key: a, b
  -> Seq Scan on t (cost=0.00..145.00 rows=10000 width=8) (actual rows=10000
  loops=1)
```

By redefining the statistics object to include n-distinct counts for the two columns, the estimate is much improved:

```
DROP STATISTICS stts;
CREATE STATISTICS stts (dependencies, ndistinct) ON a, b FROM t;
ANALYZE t;
EXPLAIN (ANALYZE, TIMING OFF) SELECT COUNT(*) FROM t GROUP BY a, b;
                                QUERY PLAN
-----
HashAggregate (cost=220.00..221.00 rows=100 width=16) (actual rows=100 loops=1)
  Group Key: a, b
  -> Seq Scan on t (cost=0.00..145.00 rows=10000 width=8) (actual rows=10000
      loops=1)
```

### 66.2.3. MCV Lists

As explained in [Section 66.2.1](#), functional dependencies are very cheap and efficient type of statistics, but their main limitation is their global nature (only tracking dependencies at the column level, not between individual column values).

This section introduces multivariate variant of MCV (most-common values) lists, a straightforward extension of the per-column statistics described in [Section 66.1](#). These statistics address the limitation by storing individual values, but it is naturally more expensive, both in terms of building the statistics in ANALYZE, storage and planning time.

Let's look at the query from [Section 66.2.1](#) again, but this time with a MCV list created on the same set of columns (be sure to drop the functional dependencies, to make sure the planner uses the newly created statistics).

```
DROP STATISTICS stts;
CREATE STATISTICS stts2 (mcv) ON a, b FROM t;
ANALYZE t;
EXPLAIN (ANALYZE, TIMING OFF) SELECT * FROM t WHERE a = 1 AND b = 1;
                                QUERY PLAN
-----
Seq Scan on t (cost=0.00..195.00 rows=100 width=8) (actual rows=100 loops=1)
  Filter: ((a = 1) AND (b = 1))
  Rows Removed by Filter: 9900
```

The estimate is as accurate as with the functional dependencies, mostly thanks to the table being fairly small and having a simple distribution with a low number of distinct values. Before looking at the second query, which was not handled by functional dependencies particularly well, let's inspect the MCV list a bit.

Inspecting the MCV list is possible using `pg_mcv_list_items` set-returning function.

```
SELECT m.* FROM pg_statistic_ext join pg_statistic_ext_data on (oid = stxoid),
           pg_mcv_list_items(stxdmcv) m WHERE stxname = 'stts2';
 index | values | nulls | frequency | base_frequency
-----+-----+-----+-----+-----
      0 | {0, 0} | {f,f} |      0.01 |          0.0001
      1 | {1, 1} | {f,f} |      0.01 |          0.0001
      ...
     49 | {49, 49} | {f,f} |      0.01 |          0.0001
     50 | {50, 50} | {f,f} |      0.01 |          0.0001
      ...
     97 | {97, 97} | {f,f} |      0.01 |          0.0001
     98 | {98, 98} | {f,f} |      0.01 |          0.0001
     99 | {99, 99} | {f,f} |      0.01 |          0.0001
```

(100 rows)

This confirms there are 100 distinct combinations in the two columns, and all of them are about equally likely (1% frequency for each one). The base frequency is the frequency computed from per-column statistics, as if there were no multi-column statistics. Had there been any null values in either of the columns, this would be identified in the `nulls` column.

When estimating the selectivity, the planner applies all the conditions on items in the MCV list, and then sums the frequencies of the matching ones.

Compared to functional dependencies, MCV lists have two major advantages. Firstly, the list stores actual values, making it possible to decide which combinations are compatible.

```
EXPLAIN (ANALYZE, TIMING OFF) SELECT * FROM t WHERE a = 1 AND b = 10;
          QUERY PLAN
-----
Seq Scan on t  (cost=0.00..195.00 rows=1 width=8) (actual rows=0 loops=1)
  Filter: ((a = 1) AND (b = 10))
  Rows Removed by Filter: 10000
```

Secondly, MCV lists handle a wider range of clause types, not just equality clauses like functional dependencies. For example, consider the following range query for the same table:

```
EXPLAIN (ANALYZE, TIMING OFF) SELECT * FROM t WHERE a <= 49 AND b > 49;
          QUERY PLAN
-----
Seq Scan on t  (cost=0.00..195.00 rows=1 width=8) (actual rows=0 loops=1)
  Filter: ((a <= 49) AND (b > 49))
  Rows Removed by Filter: 10000
```

## 66.3. Planner Statistics and Security

Access to the table `pg_statistic` is restricted to superusers, so that ordinary users cannot learn about the contents of the tables of other users from it. Some selectivity estimation functions will use a user-provided operator (either the operator appearing in the query or a related operator) to analyze the stored statistics. For example, in order to determine whether a stored most common value is applicable, the selectivity estimator will have to run the appropriate `=` operator to compare the constant in the query to the stored value. Thus the data in `pg_statistic` is potentially passed to user-defined operators. An appropriately crafted operator can intentionally leak the passed operands (for example, by logging them or writing them to a different table), or accidentally leak them by showing their values in error messages, in either case possibly exposing data from `pg_statistic` to a user who should not be able to see it.

In order to prevent this, the following applies to all built-in selectivity estimation functions. When planning a query, in order to be able to use stored statistics, the current user must either have `SELECT` privilege on the table or the involved columns, or the operator used must be `LEAKPROOF` (more accurately, the function that the operator is based on). If not, then the selectivity estimator will behave as if no statistics are available, and the planner will proceed with default or fall-back assumptions.

If a user does not have the required privilege on the table or columns, then in many cases the query will ultimately receive a permission-denied error, in which case this mechanism is invisible in practice. But if the user is reading from a security-barrier view, then the planner might wish to check the statistics of an underlying table that is otherwise inaccessible to the user. In that case, the operator should be leak-proof or the statistics will not be used. There is no direct feedback about that, except that the plan might be suboptimal. If one suspects that this is the case, one could try running the query as a more privileged user, to see if a different plan results.

This restriction applies only to cases where the planner would need to execute a user-defined operator on one or more values from `pg_statistic`. Thus the planner is permitted to use generic statistical information, such as the fraction of null values or the number of distinct values in a column, regardless of access privileges.

Selectivity estimation functions contained in third-party extensions that potentially operate on statistics with user-defined operators should follow the same security rules.

---

# Chapter 67. Backup Manifest Format

The backup manifest generated by `pg_basebackup` is primarily intended to permit the backup to be verified using `pg_verifybackup`. However, it is also possible for other tools to read the backup manifest file and use the information contained therein for their own purposes. To that end, this chapter describes the format of the backup manifest file.

A backup manifest is a JSON document encoded as UTF-8. (Although in general JSON documents are required to be Unicode, PostgreSQL permits the `json` and `jsonb` data types to be used with any supported server encoding. There is no similar exception for backup manifests.) The JSON document is always an object; the keys that are present in this object are described in the next section.

## 67.1. Backup Manifest Top-level Object

The backup manifest JSON document contains the following keys.

`PostgreSQL-Backup-Manifest-Version`

The associated value is always the integer 1.

`Files`

The associated value is always a list of objects, each describing one file that is present in the backup. No entries are present in this list for the WAL files that are needed in order to use the backup, or for the backup manifest itself. The structure of each object in the list is described in [Section 67.2](#).

`WAL-Ranges`

The associated value is always a list of objects, each describing a range of WAL records that must be readable from a particular timeline in order to make use of the backup. The structure of these objects is further described in [Section 67.3](#).

`Manifest-Checksum`

This key is always present on the last line of the backup manifest file. The associated value is a SHA256 checksum of all the preceding lines. We use a fixed checksum method here to make it possible for clients to do incremental parsing of the manifest. While a SHA256 checksum is significantly more expensive than a CRC32C checksum, the manifest should normally be small enough that the extra computation won't matter very much.

## 67.2. Backup Manifest File Object

The object which describes a single file contains either a `Path` key or an `Encoded-Path` key. Normally, the `Path` key will be present. The associated string value is the path of the file relative to the root of the backup directory. Files located in a user-defined tablespace will have paths whose first two components are `pg_tblspc` and the OID of the tablespace. If the path is not a string that is legal in UTF-8, or if the user requests that encoded paths be used for all files, then the `Encoded-Path` key will be present instead. This stores the same data, but it is encoded as a string of hexadecimal digits. Each pair of hexadecimal digits in the string represents a single octet.

The following two keys are always present:

`Size`

The expected size of this file, as an integer.

`Last-Modified`

The last modification time of the file as reported by the server at the time of the backup. Unlike the other fields stored in the backup, this field is not used by `pg_verifybackup`. It is included only for informational purposes.

If the backup was taken with file checksums enabled, the following keys will be present:

`Checksum-Algorithm`

The checksum algorithm used to compute a checksum for this file. Currently, this will be the same for every file in the backup manifest, but this may change in future releases. At present, the supported checksum algorithms are `CRC32C`, `SHA224`, `SHA256`, `SHA384`, and `SHA512`.

`Checksum`

The checksum computed for this file, stored as a series of hexadecimal characters, two for each byte of the checksum.

## 67.3. Backup Manifest WAL Range Object

The object which describes a WAL range always has three keys:

`Timeline`

The timeline for this range of WAL records, as an integer.

`Start-LSN`

The LSN at which replay must begin on the indicated timeline in order to make use of this backup. The LSN is stored in the format normally used by PostgreSQL; that is, it is a string consisting of two strings of hexadecimal characters, each with a length of between 1 and 8, separated by a slash.

`End-LSN`

The earliest LSN at which replay on the indicated timeline may end when making use of this backup. This is stored in the same format as `Start-LSN`.

Ordinarily, there will be only a single WAL range. However, if a backup is taken from a standby which switches timelines during the backup due to an upstream promotion, it is possible for multiple ranges to be present, each with a different timeline. There will never be multiple WAL ranges present for the same timeline.

# **Part VIII. Appendixes**

---

---

# Appendix A. Postgres Pro Error Codes

All messages emitted by the Postgres Pro server are assigned five-character error codes that follow the SQL standard's conventions for “SQLSTATE” codes. Applications that need to know which error condition has occurred should usually test the error code, rather than looking at the textual error message. The error codes are less likely to change across Postgres Pro releases, and also are not subject to change due to localization of error messages. Note that some, but not all, of the error codes produced by Postgres Pro are defined by the SQL standard; some additional error codes for conditions not defined by the standard have been invented or borrowed from other databases.

According to the standard, the first two characters of an error code denote a class of errors, while the last three characters indicate a specific condition within that class. Thus, an application that does not recognize the specific error code might still be able to infer what to do from the error class.

[Table A.1](#) lists all the error codes defined in Postgres Pro Standard 13.7.2. (Some are not actually used at present, but are defined by the SQL standard.) The error classes are also shown. For each error class there is a “standard” error code having the last three characters 000. This code is used only for error conditions that fall within the class but do not have any more-specific code assigned.

The symbol shown in the column “Condition Name” is the condition name to use in PL/pgSQL. Condition names can be written in either upper or lower case. (Note that PL/pgSQL does not recognize warning, as opposed to error, condition names; those are classes 00, 01, and 02.)

For some types of errors, the server reports the name of a database object (a table, table column, data type, or constraint) associated with the error; for example, the name of the unique constraint that caused a `unique_violation` error. Such names are supplied in separate fields of the error report message so that applications need not try to extract them from the possibly-localized human-readable text of the message. As of PostgreSQL 9.3, complete coverage for this feature exists only for errors in SQLSTATE class 23 (integrity constraint violation), but this is likely to be expanded in future.

**Table A.1. Postgres Pro Error Codes**

Error Code	Condition Name
<b>Class 00 — Successful Completion</b>	
00000	successful_completion
<b>Class 01 — Warning</b>	
01000	warning
0100C	dynamic_result_sets_returned
01008	implicit_zero_bit_padding
01003	null_value_eliminated_in_set_function
01007	privilege_not_granted
01006	privilege_not_revoked
01004	string_data_right_truncation
01P01	deprecated_feature
<b>Class 02 — No Data (this is also a warning class per the SQL standard)</b>	
02000	no_data
02001	no_additional_dynamic_result_sets_returned
<b>Class 03 — SQL Statement Not Yet Complete</b>	
03000	sql_statement_not_yet_complete
<b>Class 08 — Connection Exception</b>	
08000	connection_exception

<b>Error Code</b>	<b>Condition Name</b>
08003	connection_does_not_exist
08006	connection_failure
08001	sqlclient_unable_to_establish_sqlconnection
08004	sqlserver_rejected_establishment_of_sqlconnection
08007	transaction_resolution_unknown
08P01	protocol_violation
<b>Class 09 – Triggered Action Exception</b>	
09000	triggered_action_exception
<b>Class 0A – Feature Not Supported</b>	
0A000	feature_not_supported
<b>Class 0B – Invalid Transaction Initiation</b>	
0B000	invalid_transaction_initiation
<b>Class 0F – Locator Exception</b>	
0F000	locator_exception
0F001	invalid_locator_specification
<b>Class 0L – Invalid Grantor</b>	
0L000	invalid_grantor
0LP01	invalid_grant_operation
<b>Class 0P – Invalid Role Specification</b>	
0P000	invalid_role_specification
<b>Class 0Z – Diagnostics Exception</b>	
0Z000	diagnostics_exception
0Z002	stacked_diagnostics_accessed_without_active_handler
<b>Class 20 – Case Not Found</b>	
20000	case_not_found
<b>Class 21 – Cardinality Violation</b>	
21000	cardinality_violation
<b>Class 22 – Data Exception</b>	
22000	data_exception
2202E	array_subscript_error
22021	character_not_in_repertoire
22008	datetime_field_overflow
22012	division_by_zero
22005	error_in_assignment
2200B	escape_character_conflict

# Appendix B. Date/Time Support

Postgres Pro uses an internal heuristic parser for all date/time input support. Dates and times are input as strings, and are broken up into distinct fields with a preliminary determination of what kind of information can be in the field. Each field is interpreted and either assigned a numeric value, ignored, or rejected. The parser contains internal lookup tables for all textual fields, including months, days of the week, and time zones.

This appendix includes information on the content of these lookup tables and describes the steps used by the parser to decode dates and times.

## B.1. Date/Time Input Interpretation

Date/time input strings are decoded using the following procedure.

1. Break the input string into tokens and categorize each token as a string, time, time zone, or number.
  - a. If the numeric token contains a colon (:), this is a time string. Include all subsequent digits and colons.
  - b. If the numeric token contains a dash (-), slash (/), or two or more dots (.), this is a date string which might have a text month. If a date token has already been seen, it is instead interpreted as a time zone name (e.g., `America/New_York`).
  - c. If the token is numeric only, then it is either a single field or an ISO 8601 concatenated date (e.g., `19990113` for January 13, 1999) or time (e.g., `141516` for 14:15:16).
  - d. If the token starts with a plus (+) or minus (-), then it is either a numeric time zone or a special field.
2. If the token is an alphabetic string, match up with possible strings:
  - a. See if the token matches any known time zone abbreviation. These abbreviations are supplied by the configuration file described in [Section B.4](#).
  - b. If not found, search an internal table to match the token as either a special string (e.g., `today`), day (e.g., `Thursday`), month (e.g., `January`), or noise word (e.g., `at`, `on`).
  - c. If still not found, throw an error.
3. When the token is a number or number field:
  - a. If there are eight or six digits, and if no other date fields have been previously read, then interpret as a “concatenated date” (e.g., `19990118` or `990118`). The interpretation is `YYYYMMDD` or `YYMMDD`.
  - b. If the token is three digits and a year has already been read, then interpret as day of year.
  - c. If four or six digits and a year has already been read, then interpret as a time (`HHMM` or `HHMMSS`).
  - d. If three or more digits and no date fields have yet been found, interpret as a year (this forces `yy-mm-dd` ordering of the remaining date fields).
  - e. Otherwise the date field ordering is assumed to follow the `DateStyle` setting: `mm-dd-yy`, `dd-mm-yy`, or `yy-mm-dd`. Throw an error if a month or day field is found to be out of range.
4. If BC has been specified, negate the year and add one for internal storage. (There is no year zero in the Gregorian calendar, so numerically 1 BC becomes year zero.)
5. If BC was not specified, and if the year field was two digits in length, then adjust the year to four digits. If the field is less than 70, then add 2000, otherwise add 1900.

**Tip**

Gregorian years AD 1-99 can be entered by using 4 digits with leading zeros (e.g., 0099 is AD 99).

**B.2. Handling of Invalid or Ambiguous Timestamps**

Ordinarily, if a date/time string is syntactically valid but contains out-of-range field values, an error will be thrown. For example, input specifying the 31st of February will be rejected.

During a daylight-savings-time transition, it is possible for a seemingly valid timestamp string to represent a nonexistent or ambiguous timestamp. Such cases are not rejected; the ambiguity is resolved by determining which UTC offset to apply. For example, supposing that the `TimeZone` parameter is set to `America/New_York`, consider

```
=> SELECT '2018-03-11 02:30'::timestampz;
       timestampz
-----
2018-03-11 03:30:00-04
(1 row)
```

Because that day was a spring-forward transition date in that time zone, there was no civil time instant 2:30AM; clocks jumped forward from 2AM EST to 3AM EDT. Postgres Pro interprets the given time as if it were standard time (UTC-5), which then renders as 3:30AM EDT (UTC-4).

Conversely, consider the behavior during a fall-back transition:

```
=> SELECT '2018-11-04 01:30'::timestampz;
       timestampz
-----
2018-11-04 01:30:00-05
(1 row)
```

On that date, there were two possible interpretations of 1:30AM; there was 1:30AM EDT, and then an hour later after clocks jumped back from 2AM EDT to 1AM EST, there was 1:30AM EST. Again, Postgres Pro interprets the given time as if it were standard time (UTC-5). We can force the other interpretation by specifying daylight-savings time:

```
=> SELECT '2018-11-04 01:30 EDT'::timestampz;
       timestampz
-----
2018-11-04 01:30:00-04
(1 row)
```

The precise rule that is applied in such cases is that an invalid timestamp that appears to fall within a jump-forward daylight savings transition is assigned the UTC offset that prevailed in the time zone just before the transition, while an ambiguous timestamp that could fall on either side of a jump-back transition is assigned the UTC offset that prevailed just after the transition. In most time zones this is equivalent to saying that “the standard-time interpretation is preferred when in doubt”.

In all cases, the UTC offset associated with a timestamp can be specified explicitly, using either a numeric UTC offset or a time zone abbreviation that corresponds to a fixed UTC offset. The rule just given applies only when it is necessary to infer a UTC offset for a time zone in which the offset varies.

**B.3. Date/Time Key Words**

Table B.1 shows the tokens that are recognized as names of months.

**Table B.1. Month Names**

Month	Abbreviations
January	Jan
February	Feb
March	Mar
April	Apr
May	
June	Jun
July	Jul
August	Aug
September	Sep, Sept
October	Oct
November	Nov
December	Dec

Table B.2 shows the tokens that are recognized as names of days of the week.

**Table B.2. Day of the Week Names**

Day	Abbreviations
Sunday	Sun
Monday	Mon
Tuesday	Tue, Tues
Wednesday	Wed, Weds
Thursday	Thu, Thur, Thurs
Friday	Fri
Saturday	Sat

Table B.3 shows the tokens that serve various modifier purposes.

**Table B.3. Date/Time Field Modifiers**

Identifier	Description
AM	Time is before 12:00
AT	Ignored
JULIAN, JD, J	Next field is Julian Date
ON	Ignored
PM	Time is on or after 12:00
T	Next field is time

## B.4. Date/Time Configuration Files

Since timezone abbreviations are not well standardized, Postgres Pro provides a means to customize the set of abbreviations accepted by the server. The `timezone_abbreviations` run-time parameter determines the active set of abbreviations. While this parameter can be altered by any database user, the possible values for it are under the control of the database administrator — they are in fact names of configuration files stored in `.../share/timezonesets/` of the installation directory. By adding or altering files in that directory, the administrator can set local policy for timezone abbreviations.

`timezone_abbreviations` can be set to any file name found in `.../share/timezonesets/`, if the file's name is entirely alphabetic. (The prohibition against non-alphabetic characters in `timezone_abbreviations` prevents reading files outside the intended directory, as well as reading editor backup files and other extraneous files.)

A timezone abbreviation file can contain blank lines and comments beginning with `#`. Non-comment lines must have one of these formats:

```
zone_abbreviation offset
zone_abbreviation offset D
zone_abbreviation time_zone_name
@INCLUDE file_name
@OVERRIDE
```

A `zone_abbreviation` is just the abbreviation being defined. An `offset` is an integer giving the equivalent offset in seconds from UTC, positive being east from Greenwich and negative being west. For example, `-18000` would be five hours west of Greenwich, or North American east coast standard time. `D` indicates that the zone name represents local daylight-savings time rather than standard time.

Alternatively, a `time_zone_name` can be given, referencing a zone name defined in the IANA timezone database. The zone's definition is consulted to see whether the abbreviation is or has been in use in that zone, and if so, the appropriate meaning is used — that is, the meaning that was currently in use at the timestamp whose value is being determined, or the meaning in use immediately before that if it wasn't current at that time, or the oldest meaning if it was used only after that time. This behavior is essential for dealing with abbreviations whose meaning has historically varied. It is also allowed to define an abbreviation in terms of a zone name in which that abbreviation does not appear; then using the abbreviation is just equivalent to writing out the zone name.

### Tip

Using a simple integer `offset` is preferred when defining an abbreviation whose offset from UTC has never changed, as such abbreviations are much cheaper to process than those that require consulting a time zone definition.

The `@INCLUDE` syntax allows inclusion of another file in the `.../share/timezonesets/` directory. Inclusion can be nested, to a limited depth.

The `@OVERRIDE` syntax indicates that subsequent entries in the file can override previous entries (typically, entries obtained from included files). Without this, conflicting definitions of the same timezone abbreviation are considered an error.

In an unmodified installation, the file `Default` contains all the non-conflicting time zone abbreviations for most of the world. Additional files `Australia` and `India` are provided for those regions: these files first include the `Default` file and then add or modify abbreviations as needed.

For reference purposes, a standard installation also contains files `Africa.txt`, `America.txt`, etc, containing information about every time zone abbreviation known to be in use according to the IANA timezone database. The zone name definitions found in these files can be copied and pasted into a custom configuration file as needed. Note that these files cannot be directly referenced as `timezone_abbreviations` settings, because of the dot embedded in their names.

### Note

If an error occurs while reading the time zone abbreviation set, no new value is applied and the old set is kept. If the error occurs while starting the database, startup fails.

**Caution**

Time zone abbreviations defined in the configuration file override non-timezone meanings built into Postgres Pro. For example, the `Australia` configuration file defines `SAT` (for South Australian Standard Time). When this file is active, `SAT` will not be recognized as an abbreviation for Saturday.

**Caution**

If you modify files in `.../share/timezonesets/`, it is up to you to make backups — a normal database dump will not include this directory.

**B.5. POSIX Time Zone Specifications**

Postgres Pro can accept time zone specifications that are written according to the POSIX standard's rules for the `TZ` environment variable. POSIX time zone specifications are inadequate to deal with the complexity of real-world time zone history, but there are sometimes reasons to use them.

A POSIX time zone specification has the form

```
STD offset [ DST [ dstoffset ] [ , rule ] ]
```

(For readability, we show spaces between the fields, but spaces should not be used in practice.) The fields are:

- *STD* is the zone abbreviation to be used for standard time.
- *offset* is the zone's standard-time offset from UTC.
- *DST* is the zone abbreviation to be used for daylight-savings time. If this field and the following ones are omitted, the zone uses a fixed UTC offset with no daylight-savings rule.
- *dstoffset* is the daylight-savings offset from UTC. This field is typically omitted, since it defaults to one hour less than the standard-time *offset*, which is usually the right thing.
- *rule* defines the rule for when daylight savings is in effect, as described below.

In this syntax, a zone abbreviation can be a string of letters, such as `EST`, or an arbitrary string surrounded by angle brackets, such as `<UTC-05>`. Note that the zone abbreviations given here are only used for output, and even then only in some timestamp output formats. The zone abbreviations recognized in timestamp input are determined as explained in [Section B.4](#).

The offset fields specify the hours, and optionally minutes and seconds, difference from UTC. They have the format *hh*[*:mm*[:*ss*]] optionally with a leading sign (+ or -). The positive sign is used for zones west of Greenwich. (Note that this is the opposite of the ISO-8601 sign convention used elsewhere in Postgres Pro.) *hh* can have one or two digits; *mm* and *ss* (if used) must have two.

The daylight-savings transition *rule* has the format

```
dstdate [ / dsttime ] , stddate [ / stdtime ]
```

(As before, spaces should not be included in practice.) The *dstdate* and *dsttime* fields define when daylight-savings time starts, while *stddate* and *stdtime* define when standard time starts. (In some cases, notably in zones south of the equator, the former might be later in the year than the latter.) The date fields have one of these formats:

*n*  
A plain integer denotes a day of the year, counting from zero to 364, or to 365 in leap years.

*Jn*  
In this form, *n* counts from 1 to 365, and February 29 is not counted even if it is present. (Thus, a transition occurring on February 29 could not be specified this way. However, days after February

have the same numbers whether it's a leap year or not, so that this form is usually more useful than the plain-integer form for transitions on fixed dates.)

*Mm.n.d*

This form specifies a transition that always happens during the same month and on the same day of the week. *m* identifies the month, from 1 to 12. *n* specifies the *n*'th occurrence of the weekday identified by *d*. *n* is a number between 1 and 4, or 5 meaning the last occurrence of that weekday in the month (which could be the fourth or the fifth). *d* is a number between 0 and 6, with 0 indicating Sunday. For example, `M3.2.0` means “the second Sunday in March”.

### Note

The `M` format is sufficient to describe many common daylight-savings transition laws. But note that none of these variants can deal with daylight-savings law changes, so in practice the historical data stored for named time zones (in the IANA time zone database) is necessary to interpret past time stamps correctly.

The time fields in a transition rule have the same format as the offset fields described previously, except that they cannot contain signs. They define the current local time at which the change to the other time occurs. If omitted, they default to `02:00:00`.

If a daylight-savings abbreviation is given but the transition *rule* field is omitted, the fallback behavior is to use the rule `M3.2.0,M11.1.0`, which corresponds to USA practice as of 2020 (that is, spring forward on the second Sunday of March, fall back on the first Sunday of November, both transitions occurring at 2AM prevailing time). Note that this rule does not give correct USA transition dates for years before 2007.

As an example, `CET-1CEST,M3.5.0,M10.5.0/3` describes current (as of 2020) timekeeping practice in Paris. This specification says that standard time has the abbreviation `CET` and is one hour ahead (east) of UTC; daylight savings time has the abbreviation `CEST` and is implicitly two hours ahead of UTC; daylight savings time begins on the last Sunday in March at 2AM CET and ends on the last Sunday in October at 3AM CEST.

The four timezone names `EST5EDT`, `CST6CDT`, `MST7MDT`, and `PST8PDT` look like they are POSIX zone specifications. However, they actually are treated as named time zones because (for historical reasons) there are files by those names in the IANA time zone database. The practical implication of this is that these zone names will produce valid historical USA daylight-savings transitions, even when a plain POSIX specification would not.

One should be wary that it is easy to misspell a POSIX-style time zone specification, since there is no check on the reasonableness of the zone abbreviation(s). For example, `SET TIMEZONE TO FOOBAR0` will work, leaving the system effectively using a rather peculiar abbreviation for UTC.

## B.6. History of Units

The SQL standard states that “Within the definition of a ‘datetime literal’, the ‘datetime values’ are constrained by the natural rules for dates and times according to the Gregorian calendar”. PostgreSQL follows the SQL standard's lead by counting dates exclusively in the Gregorian calendar, even for years before that calendar was in use. This rule is known as the *proleptic Gregorian calendar*.

The Julian calendar was introduced by Julius Caesar in 45 BC. It was in common use in the Western world until the year 1582, when countries started changing to the Gregorian calendar. In the Julian calendar, the tropical year is approximated as  $365 \frac{1}{4}$  days = 365.25 days. This gives an error of about 1 day in 128 years.

The accumulating calendar error prompted Pope Gregory XIII to reform the calendar in accordance with instructions from the Council of Trent. In the Gregorian calendar, the tropical year is approximated as

$365 + 97 / 400$  days = 365.2425 days. Thus it takes approximately 3300 years for the tropical year to shift one day with respect to the Gregorian calendar.

The approximation  $365+97/400$  is achieved by having 97 leap years every 400 years, using the following rules:

Every year divisible by 4 is a leap year.

However, every year divisible by 100 is not a leap year.

However, every year divisible by 400 is a leap year after all.

So, 1700, 1800, 1900, 2100, and 2200 are not leap years. But 1600, 2000, and 2400 are leap years. By contrast, in the older Julian calendar all years divisible by 4 are leap years.

The papal bull of February 1582 decreed that 10 days should be dropped from October 1582 so that 15 October should follow immediately after 4 October. This was observed in Italy, Poland, Portugal, and Spain. Other Catholic countries followed shortly after, but Protestant countries were reluctant to change, and the Greek Orthodox countries didn't change until the start of the 20th century. The reform was observed by Great Britain and its dominions (including what is now the USA) in 1752. Thus 2 September 1752 was followed by 14 September 1752. This is why Unix systems that have the `cal` program produce the following:

```
$ cal 9 1752
   September 1752
  S  M Tu  W Th  F  S
           1  2 14 15 16
17 18 19 20 21 22 23
24 25 26 27 28 29 30
```

But, of course, this calendar is only valid for Great Britain and dominions, not other places. Since it would be difficult and confusing to try to track the actual calendars that were in use in various places at various times, Postgres Pro does not try, but rather follows the Gregorian calendar rules for all dates, even though this method is not historically accurate.

Different calendars have been developed in various parts of the world, many predating the Gregorian system. For example, the beginnings of the Chinese calendar can be traced back to the 14th century BC. Legend has it that the Emperor Huangdi invented that calendar in 2637 BC. The People's Republic of China uses the Gregorian calendar for civil purposes. The Chinese calendar is used for determining festivals.

## B.7. Julian Dates

The *Julian Date* system is a method for numbering days. It is unrelated to the Julian calendar, though it is confusingly named similarly to that calendar. The Julian Date system was invented by the French scholar Joseph Justus Scaliger (1540–1609) and probably takes its name from Scaliger's father, the Italian scholar Julius Caesar Scaliger (1484–1558).

In the Julian Date system, each day has a sequential number, starting from JD 0 (which is sometimes called *the* Julian Date). JD 0 corresponds to 1 January 4713 BC in the Julian calendar, or 24 November 4714 BC in the Gregorian calendar. Julian Date counting is most often used by astronomers for labeling their nightly observations, and therefore a date runs from noon UTC to the next noon UTC, rather than from midnight to midnight: JD 0 designates the 24 hours from noon UTC on 24 November 4714 BC to noon UTC on 25 November 4714 BC.

Although Postgres Pro supports Julian Date notation for input and output of dates (and also uses Julian dates for some internal datetime calculations), it does not observe the nicety of having dates run from noon to noon. Postgres Pro treats a Julian Date as running from local midnight to local midnight, the same as a normal date.

This definition does, however, provide a way to obtain the astronomical definition when you need it: do the arithmetic in time zone `UTC+12`. For example,

```
=> SELECT extract(julian from '2021-06-23 7:00:00-04'::timestampz at time zone 'UTC  
+12');
```

```
date_part
```

```
-----  
2459388.9583333335
```

```
(1 row)
```

```
=> SELECT extract(julian from '2021-06-23 8:00:00-04'::timestampz at time zone 'UTC  
+12');
```

```
date_part
```

```
-----  
2459389
```

```
(1 row)
```

```
=> SELECT extract(julian from date '2021-06-23');
```

```
date_part
```

```
-----  
2459389
```

```
(1 row)
```

---

# Appendix C. SQL Key Words

[Table C.1](#) lists all tokens that are key words in the SQL standard and in Postgres Pro Standard 13.7.2. Background information can be found in [Section 4.1.1](#). (For space reasons, only the latest two versions of the SQL standard, and SQL-92 for historical comparison, are included. The differences between those and the other intermediate standard versions are small.)

SQL distinguishes between *reserved* and *non-reserved* key words. According to the standard, reserved key words are the only real key words; they are never allowed as identifiers. Non-reserved key words only have a special meaning in particular contexts and can be used as identifiers in other contexts. Most non-reserved key words are actually the names of built-in tables and functions specified by SQL. The concept of non-reserved key words essentially only exists to declare that some predefined meaning is attached to a word in some contexts.

In the Postgres Pro parser life is a bit more complicated. There are several different classes of tokens ranging from those that can never be used as an identifier to those that have absolutely no special status in the parser as compared to an ordinary identifier. (The latter is usually the case for functions specified by SQL.) Even reserved key words are not completely reserved in Postgres Pro, but can be used as column labels (for example, `SELECT 55 AS CHECK`, even though `CHECK` is a reserved key word).

In [Table C.1](#) in the column for Postgres Pro we classify as “non-reserved” those key words that are explicitly known to the parser but are allowed as column or table names. Some key words that are otherwise non-reserved cannot be used as function or data type names and are marked accordingly. (Most of these words represent built-in functions or data types with special syntax. The function or type is still available but it cannot be redefined by the user.) Labeled “reserved” are those tokens that are not allowed as column or table names. Some reserved key words are allowable as names for functions or data types; this is also shown in the table. If not so marked, a reserved key word is only allowed as an “AS” column label name.

As a general rule, if you get spurious parser errors for commands that contain any of the listed key words as an identifier you should try to quote the identifier to see if the problem goes away.

It is important to understand before studying [Table C.1](#) that the fact that a key word is not reserved in Postgres Pro does not mean that the feature related to the word is not implemented. Conversely, the presence of a key word does not indicate the existence of a feature.

# Appendix D. SQL Conformance

This section attempts to outline to what extent Postgres Pro conforms to the current SQL standard. The following information is not a full statement of conformance, but it presents the main topics in as much detail as is both reasonable and useful for users.

The formal name of the SQL standard is ISO/IEC 9075 “Database Language SQL”. A revised version of the standard is released from time to time; the most recent update appearing in 2016. The 2016 version is referred to as ISO/IEC 9075:2016, or simply as SQL:2016. The versions prior to that were SQL:2011, SQL:2008, SQL:2006, SQL:2003, SQL:1999, and SQL-92. Each version replaces the previous one, so claims of conformance to earlier versions have no official merit. Postgres Pro development aims for conformance with the latest official version of the standard where such conformance does not contradict traditional features or common sense. Many of the features required by the SQL standard are supported, though sometimes with slightly differing syntax or function. Further moves towards conformance can be expected over time.

SQL-92 defined three feature sets for conformance: Entry, Intermediate, and Full. Most database management systems claiming SQL standard conformance were conforming at only the Entry level, since the entire set of features in the Intermediate and Full levels was either too voluminous or in conflict with legacy behaviors.

Starting with SQL:1999, the SQL standard defines a large set of individual features rather than the ineffectively broad three levels found in SQL-92. A large subset of these features represents the “Core” features, which every conforming SQL implementation must supply. The rest of the features are purely optional.

The standard versions beginning with SQL:2003 are also split into a number of parts. Each is known by a shorthand name. Note that these parts are not consecutively numbered.

- ISO/IEC 9075-1 Framework (SQL/Framework)
- ISO/IEC 9075-2 Foundation (SQL/Foundation)
- ISO/IEC 9075-3 Call Level Interface (SQL/CLI)
- ISO/IEC 9075-4 Persistent Stored Modules (SQL/PSM)
- ISO/IEC 9075-9 Management of External Data (SQL/MED)
- ISO/IEC 9075-10 Object Language Bindings (SQL/OLB)
- ISO/IEC 9075-11 Information and Definition Schemas (SQL/Schemata)
- ISO/IEC 9075-13 Routines and Types using the Java Language (SQL/JRT)
- ISO/IEC 9075-14 XML-related specifications (SQL/XML)
- ISO/IEC 9075-15 Multi-dimensional arrays (SQL/MDA)

The Postgres Pro core covers parts 1, 2, 9, 11, and 14. Part 3 is covered by the ODBC driver, and part 13 is covered by the PL/Java plug-in, but exact conformance is currently not being verified for these components. There are currently no implementations of parts 4, 10, and 15 for Postgres Pro.

Postgres Pro supports most of the major features of SQL:2016. Out of 177 mandatory features required for full Core conformance, Postgres Pro conforms to at least 170. In addition, there is a long list of supported optional features. It might be worth noting that at the time of writing, no current version of any database management system claims full conformance to Core SQL:2016.

In the following two sections, we provide a list of those features that Postgres Pro supports, followed by a list of the features defined in SQL:2016 which are not yet supported in Postgres Pro. Both of these lists are approximate: There might be minor details that are nonconforming for a feature that is listed as supported, and large parts of an unsupported feature might in fact be implemented. The main body of the documentation always contains the most accurate information about what does and does not work.

### Note

Feature codes containing a hyphen are subfeatures. Therefore, if a particular subfeature is not supported, the main feature is listed as unsupported even if some other subfeatures are supported.

## D.1. Supported Features

Identifier	Core?	Description	Comment
B012		Embedded C	
B021		Direct SQL	
E011	Core	Numeric data types	
E011-01	Core	INTEGER and SMALLINT data types	
E011-02	Core	REAL, DOUBLE PRECISION, and FLOAT data types	
E011-03	Core	DECIMAL and NUMERIC data types	
E011-04	Core	Arithmetic operators	
E011-05	Core	Numeric comparison	
E011-06	Core	Implicit casting among the numeric data types	
E021	Core	Character data types	
E021-01	Core	CHARACTER data type	
E021-02	Core	CHARACTER VARYING data type	
E021-03	Core	Character literals	
E021-04	Core	CHARACTER_LENGTH function	trims trailing spaces from CHARACTER values before counting
E021-05	Core	OCTET_LENGTH function	
E021-06	Core	SUBSTRING function	
E021-07	Core	Character concatenation	
E021-08	Core	UPPER and LOWER functions	
E021-09	Core	TRIM function	
E021-10	Core	Implicit casting among the character string types	
E021-11	Core	POSITION function	
E021-12	Core	Character comparison	
E031	Core	Identifiers	
E031-01	Core	Delimited identifiers	
E031-02	Core	Lower case identifiers	
E031-03	Core	Trailing underscore	
E051	Core	Basic query specification	
E051-01	Core	SELECT DISTINCT	
E051-02	Core	GROUP BY clause	

Identifier	Core?	Description	Comment
E051-04	Core	GROUP BY can contain columns not in <select list>	
E051-05	Core	Select list items can be renamed	
E051-06	Core	HAVING clause	
E051-07	Core	Qualified * in select list	
E051-08	Core	Correlation names in the FROM clause	
E051-09	Core	Rename columns in the FROM clause	
E061	Core	Basic predicates and search conditions	
E061-01	Core	Comparison predicate	
E061-02	Core	BETWEEN predicate	
E061-03	Core	IN predicate with list of values	
E061-04	Core	LIKE predicate	
E061-05	Core	LIKE predicate ESCAPE clause	
E061-06	Core	NULL predicate	
E061-07	Core	Quantified comparison predicate	
E061-08	Core	EXISTS predicate	
E061-09	Core	Subqueries in comparison predicate	
E061-11	Core	Subqueries in IN predicate	
E061-12	Core	Subqueries in quantified comparison predicate	
E061-13	Core	Correlated subqueries	
E061-14	Core	Search condition	
E071	Core	Basic query expressions	
E071-01	Core	UNION DISTINCT table operator	
E071-02	Core	UNION ALL table operator	
E071-03	Core	EXCEPT DISTINCT table operator	
E071-05	Core	Columns combined via table operators need not have exactly the same data type	
E071-06	Core	Table operators in subqueries	
E081	Core	Basic Privileges	
E081-01	Core	SELECT privilege	
E081-02	Core	DELETE privilege	
E081-03	Core	INSERT privilege at the table level	
E081-04	Core	UPDATE privilege at the table level	
E081-05	Core	UPDATE privilege at the column level	
E081-06	Core	REFERENCES privilege at the table level	
E081-07	Core	REFERENCES privilege at the column level	
E081-08	Core	WITH GRANT OPTION	
E081-09	Core	USAGE privilege	
E081-10	Core	EXECUTE privilege	
E091	Core	Set functions	
E091-01	Core	AVG	
E091-02	Core	COUNT	

<b>Identifier</b>	<b>Core?</b>	<b>Description</b>	<b>Comment</b>
E091-03	Core	MAX	
E091-04	Core	MIN	
E091-05	Core	SUM	
E091-06	Core	ALL quantifier	
E091-07	Core	DISTINCT quantifier	
E101	Core	Basic data manipulation	
E101-01	Core	INSERT statement	
E101-03	Core	Searched UPDATE statement	
E101-04	Core	Searched DELETE statement	
E111	Core	Single row SELECT statement	
E121	Core	Basic cursor support	
E121-01	Core	DECLARE CURSOR	
E121-02	Core	ORDER BY columns need not be in select list	
E121-03	Core	Value expressions in ORDER BY clause	
E121-04	Core	OPEN statement	
E121-06	Core	Positioned UPDATE statement	
E121-07	Core	Positioned DELETE statement	
E121-08	Core	CLOSE statement	
E121-10	Core	FETCH statement implicit NEXT	
E121-17	Core	WITH HOLD cursors	
E131	Core	Null value support (nulls in lieu of values)	
E141	Core	Basic integrity constraints	
E141-01	Core	NOT NULL constraints	
E141-02	Core	UNIQUE constraints of NOT NULL columns	
E141-03	Core	PRIMARY KEY constraints	
E141-04	Core	Basic FOREIGN KEY constraint with the NO ACTION default for both referential delete action and referential update action	
E141-06	Core	CHECK constraints	
E141-07	Core	Column defaults	
E141-08	Core	NOT NULL inferred on PRIMARY KEY	
E141-10	Core	Names in a foreign key can be specified in any order	
E151	Core	Transaction support	
E151-01	Core	COMMIT statement	
E151-02	Core	ROLLBACK statement	
E152	Core	Basic SET TRANSACTION statement	
E152-01	Core	SET TRANSACTION statement: ISOLATION LEVEL SERIALIZABLE clause	
E152-02	Core	SET TRANSACTION statement: READ ONLY and READ WRITE clauses	
E153	Core	Updatable queries with subqueries	
E161	Core	SQL comments using leading double minus	

Identifier	Core?	Description	Comment
E171	Core	SQLSTATE support	
E182	Core	Host language binding	
F021	Core	Basic information schema	
F021-01	Core	COLUMNS view	
F021-02	Core	TABLES view	
F021-03	Core	VIEWS view	
F021-04	Core	TABLE_CONSTRAINTS view	
F021-05	Core	REFERENTIAL_CONSTRAINTS view	
F021-06	Core	CHECK_CONSTRAINTS view	
F031	Core	Basic schema manipulation	
F031-01	Core	CREATE TABLE statement to create persistent base tables	
F031-02	Core	CREATE VIEW statement	
F031-03	Core	GRANT statement	
F031-04	Core	ALTER TABLE statement: ADD COLUMN clause	
F031-13	Core	DROP TABLE statement: RESTRICT clause	
F031-16	Core	DROP VIEW statement: RESTRICT clause	
F031-19	Core	REVOKE statement: RESTRICT clause	
F032		CASCADE drop behavior	
F033		ALTER TABLE statement: DROP COLUMN clause	
F034		Extended REVOKE statement	
F034-01		REVOKE statement performed by other than the owner of a schema object	
F034-02		REVOKE statement: GRANT OPTION FOR clause	
F034-03		REVOKE statement to revoke a privilege that the grantee has WITH GRANT OPTION	
F041	Core	Basic joined table	
F041-01	Core	Inner join (but not necessarily the INNER keyword)	
F041-02	Core	INNER keyword	
F041-03	Core	LEFT OUTER JOIN	
F041-04	Core	RIGHT OUTER JOIN	
F041-05	Core	Outer joins can be nested	
F041-07	Core	The inner table in a left or right outer join can also be used in an inner join	
F041-08	Core	All comparison operators are supported (rather than just =)	
F051	Core	Basic date and time	
F051-01	Core	DATE data type (including support of DATE literal)	
F051-02	Core	TIME data type (including support of TIME literal) with fractional seconds precision of at least 0	
F051-03	Core	TIMESTAMP data type (including support of TIMESTAMP literal) with fractional seconds precision of at least 0 and 6	

Identifier	Core?	Description	Comment
F051-04	Core	Comparison predicate on DATE, TIME, and TIMESTAMP data types	
F051-05	Core	Explicit CAST between datetime types and character string types	
F051-06	Core	CURRENT_DATE	
F051-07	Core	LOCALTIME	
F051-08	Core	LOCALTIMESTAMP	
F052		Intervals and datetime arithmetic	
F053		OVERLAPS predicate	
F081	Core	UNION and EXCEPT in views	
F111		Isolation levels other than SERIALIZABLE	
F111-01		READ UNCOMMITTED isolation level	
F111-02		READ COMMITTED isolation level	
F111-03		REPEATABLE READ isolation level	
F131	Core	Grouped operations	
F131-01	Core	WHERE, GROUP BY, and HAVING clauses supported in queries with grouped views	
F131-02	Core	Multiple tables supported in queries with grouped views	
F131-03	Core	Set functions supported in queries with grouped views	
F131-04	Core	Subqueries with GROUP BY and HAVING clauses and grouped views	
F131-05	Core	Single row SELECT with GROUP BY and HAVING clauses and grouped views	
F171		Multiple schemas per user	
F181	Core	Multiple module support	
F191		Referential delete actions	
F200		TRUNCATE TABLE statement	
F201	Core	CAST function	
F202		TRUNCATE TABLE: identity column restart option	
F221	Core	Explicit defaults	
F222		INSERT statement: DEFAULT VALUES clause	
F231		Privilege tables	
F231-01		TABLE_PRIVILEGES view	
F231-02		COLUMN_PRIVILEGES view	
F231-03		USAGE_PRIVILEGES view	
F251		Domain support	
F261	Core	CASE expression	
F261-01	Core	Simple CASE	
F261-02	Core	Searched CASE	
F261-03	Core	NULLIF	
F261-04	Core	COALESCE	
F262		Extended CASE expression	

Identifier	Core?	Description	Comment
F271		Compound character literals	
F281		LIKE enhancements	
F302		INTERSECT table operator	
F302-01		INTERSECT DISTINCT table operator	
F302-02		INTERSECT ALL table operator	
F304		EXCEPT ALL table operator	
F311	Core	Schema definition statement	
F311-01	Core	CREATE SCHEMA	
F311-02	Core	CREATE TABLE for persistent base tables	
F311-03	Core	CREATE VIEW	
F311-04	Core	CREATE VIEW: WITH CHECK OPTION	
F311-05	Core	GRANT statement	
F321		User authorization	
F361		Subprogram support	
F381		Extended schema manipulation	
F381-01		ALTER TABLE statement: ALTER COLUMN clause	
F381-02		ALTER TABLE statement: ADD CONSTRAINT clause	
F381-03		ALTER TABLE statement: DROP CONSTRAINT clause	
F382		Alter column data type	
F383		Set column not null clause	
F384		Drop identity property clause	
F385		Drop column generation expression clause	
F386		Set identity column generation clause	
F391		Long identifiers	
F392		Unicode escapes in identifiers	
F393		Unicode escapes in literals	
F394		Optional normal form specification	
F401		Extended joined table	
F401-01		NATURAL JOIN	
F401-02		FULL OUTER JOIN	
F401-04		CROSS JOIN	
F402		Named column joins for LOBs, arrays, and multisets	
F411		Time zone specification	differences regarding literal interpretation
F421		National character	
F431		Read-only scrollable cursors	
F431-01		FETCH with explicit NEXT	
F431-02		FETCH FIRST	
F431-03		FETCH LAST	
F431-04		FETCH PRIOR	
F431-05		FETCH ABSOLUTE	

Identifier	Core?	Description	Comment
F431-06		FETCH RELATIVE	
F441		Extended set function support	
F442		Mixed column references in set functions	
F471	Core	Scalar subquery values	
F481	Core	Expanded NULL predicate	
F491		Constraint management	
F501	Core	Features and conformance views	
F501-01	Core	SQL_FEATURES view	
F501-02	Core	SQL_SIZING view	
F502		Enhanced documentation tables	
F531		Temporary tables	
F555		Enhanced seconds precision	
F561		Full value expressions	
F571		Truth value tests	
F591		Derived tables	
F611		Indicator data types	
F641		Row and table constructors	
F651		Catalog name qualifiers	
F661		Simple tables	
F672		Retrospective check constraints	
F690		Collation support	but no character set support
F692		Extended collation support	
F701		Referential update actions	
F711		ALTER domain	
F731		INSERT column privileges	
F751		View CHECK enhancements	
F761		Session management

F855		Nested <order by clause> in <query expression>	
F856		Nested <fetch first clause> in <query expression>	
F857		Top-level <fetch first clause> in <query expression>	
F858		<fetch first clause> in subqueries	

Identifier	Core?	Description	Comment
F859		Top-level <fetch first clause> in views	
F860		<fetch first row count> in <fetch first clause>	
F861		Top-level <result offset clause> in <query expression>	
F862		<result offset clause> in subqueries	
F863		Nested <result offset clause> in <query expression>	
F864		Top-level <result offset clause> in views	
F865		<offset row count> in <result offset clause>	
F867		FETCH FIRST clause: WITH TIES option	
S071		SQL paths in function and type name resolution	
S092		Arrays of user-defined types	
S095		Array constructors by query	
S096		Optional array bounds	
S098		ARRAY_AGG	
S111		ONLY in query expressions	
S201		SQL-invoked routines on arrays	
S201-01		Array parameters	
S201-02		Array as result type of functions	
S211		User-defined cast functions	
S301		Enhanced UNNEST	
T031		BOOLEAN data type	
T071		BIGINT data type	
T121		WITH (excluding RECURSIVE) in query expression	
T122		WITH (excluding RECURSIVE) in subquery	
T131		Recursive query	
T132		Recursive query in subquery	
T141		SIMILAR predicate	
T151		DISTINCT predicate	
T152		DISTINCT predicate with negation	
T171		LIKE clause in table definition	
T172		AS subquery clause in table definition	
T173		Extended LIKE clause in table definition	
T174		Identity columns	
T177		Sequence generator support: simple restart option	
T178		Identity columns: simple restart option	
T191		Referential action RESTRICT	
T201		Comparable data types for referential constraints	
T211-01		Triggers activated on UPDATE, INSERT, or DELETE of one base table	
T211-02		BEFORE triggers	
T211-03		AFTER triggers	
T211-04		FOR EACH ROW triggers	

Identifier	Core?	Description	Comment
T211-05		Ability to specify a search condition that must be true before the trigger is invoked	
T211-07		TRIGGER privilege	
T212		Enhanced trigger capability	
T213		INSTEAD OF triggers	
T231		Sensitive cursors	
T241		START TRANSACTION statement	
T261		Chained transactions	
T271		Savepoints	
T281		SELECT privilege with column granularity	
T285		Enhanced derived column names	
T312		OVERLAY function	
T321-01	Core	User-defined functions with no overloading	
T321-02	Core	User-defined stored procedures with no overloading	
T321-03	Core	Function invocation	
T321-04	Core	CALL statement	
T321-06	Core	ROUTINES view

X121		XML parameters in external routines	
X221		XML passing mechanism BY VALUE	
X301		XMLTable: derived column list option	
X302		XMLTable: ordinality column option	
X303		XMLTable: column default option	
X304		XMLTable: passing a context item	must be XML DOCUMENT
X400		Name and identifier mapping	
X410		Alter column data type: XML type	

## D.2. Unsupported Features

The following features defined in SQL:2016 are not implemented in this release of Postgres Pro. In a few cases, equivalent functionality is available.

Identifier	Core?	Description	Comment
B011		Embedded Ada	
B013		Embedded COBOL	
B014		Embedded Fortran	
B015		Embedded MUMPS	
B016		Embedded Pascal	
B017		Embedded PL/I	
B031		Basic dynamic SQL	
B032		Extended dynamic SQL	

<b>Identifier</b>	<b>Core?</b>	<b>Description</b>	<b>Comment</b>
B032-01		<describe input statement>	
B033		Untyped SQL-invoked function arguments	
B034		Dynamic specification of cursor attributes	
B035		Non-extended descriptor names	
B041		Extensions to embedded SQL exception declarations	
B051		Enhanced execution rights	
B111		Module language Ada	
B112		Module language C	
B113		Module language COBOL	
B114		Module language Fortran	
B115		Module language MUMPS	
B116		Module language Pascal	
B117		Module language PL/I	
B121		Routine language Ada	
B122		Routine language C	
B123		Routine language COBOL	
B124		Routine language Fortran	
B125		Routine language MUMPS	
B126		Routine language Pascal	
B127		Routine language PL/I	
B128		Routine language SQL	
B200		Polymorphic table functions	
B201		More than one PTF generic table parameter	
B202		PTF Copartitioning	
B203		More than one copartition specification	
B204		PRUNE WHEN EMPTY	
B205		Pass-through columns	
B206		PTF descriptor parameters	
B207		Cross products of partitionings	
B208		PTF component procedure interface	
B209		PTF extended names	
B211		Module language Ada: VARCHAR and NUMERIC support	
B221		Routine language Ada: VARCHAR and NUMERIC support	
F054		TIMESTAMP in DATE type precedence list	
F121		Basic diagnostics management	
F121-01		GET DIAGNOSTICS statement	
F121-02		SET TRANSACTION statement: DIAGNOSTICS SIZE clause	
F122		Enhanced diagnostics management	
F123		All diagnostics	

Identifier	Core?	Description	Comment
F263		Comma-separated predicates in simple CASE expression	
F291		UNIQUE predicate	
F301		CORRESPONDING in query expressions	
F312		MERGE statement	consider INSERT ... ON CONFLICT DO UPDATE
F313		Enhanced MERGE statement	
F314		MERGE statement with DELETE branch	
F341		Usage tables	no ROUTINE_*_USAGE tables
F403		Partitioned joined tables	
F404		Range variable for common column names	
F451		Character set definition	
F461		Named character sets	
F492		Optional table constraint enforcement	
F521		Assertions	
F671		Subqueries in CHECK	intentionally omitted
F673		Reads SQL-data routine invocations in CHECK constraints	
F693		SQL-session and client module collations	
F695		Translation support	
F696		Additional translation documentation	
F721		Deferrable constraints	foreign and unique keys only
F741		Referential MATCH types	no partial match yet
F812	Core	Basic flagging	
F813		Extended flagging	
F821		Local table references	
F831		Full cursor update	
F831-01		Updatable scrollable cursors	
F831-02		Updatable ordered cursors	
F841		LIKE_REGEX predicate	
F842		OCCURRENCES_REGEX function	
F843		POSITION_REGEX function	
F844		SUBSTRING_REGEX function	
F845		TRANSLATE_REGEX function	
F846		Octet support in regular expression operators	
F847		Nonconstant regular expressions	
F866		FETCH FIRST clause: PERCENT option	
R010		Row pattern recognition: FROM clause	
R020		Row pattern recognition: WINDOW clause	
R030		Row pattern recognition: full aggregate support

X305		XMLTable: initializing an XQuery variable	

### D.3. XML Limits and Conformance to SQL/XML

Significant revisions to the XML-related specifications in ISO/IEC 9075-14 (SQL/XML) were introduced with SQL:2006. Postgres Pro's implementation of the XML data type and related functions largely follows the earlier 2003 edition, with some borrowing from later editions. In particular:

- Where the current standard provides a family of XML data types to hold “document” or “content” in untyped or XML Schema-typed variants, and a type `XML (SEQUENCE)` to hold arbitrary pieces of XML content, Postgres Pro provides the single `xml` type, which can hold “document” or “content”. There is no equivalent of the standard's “sequence” type.
- Postgres Pro provides two functions introduced in SQL:2006, but in variants that use the XPath 1.0 language, rather than XML Query as specified for them in the standard.

This section presents some of the resulting differences you may encounter.

### D.3.1. Queries Are Restricted to XPath 1.0

The Postgres Pro-specific functions `xpath()` and `xpath_exists()` query XML documents using the XPath language. Postgres Pro also provides XPath-only variants of the standard functions `XMLEXISTS` and `XMLTABLE`, which officially use the XQuery language. For all of these functions, Postgres Pro relies on the `libxml2` library, which provides only XPath 1.0.

There is a strong connection between the XQuery language and XPath versions 2.0 and later: any expression that is syntactically valid and executes successfully in both produces the same result (with a minor exception for expressions containing numeric character references or predefined entity references, which XQuery replaces with the corresponding character while XPath leaves them alone). But there is no such connection between these languages and XPath 1.0; it was an earlier language and differs in many respects.

There are two categories of limitation to keep in mind: the restriction from XQuery to XPath for the functions specified in the SQL standard, and the restriction of XPath to version 1.0 for both the standard and the Postgres Pro-specific functions.

#### D.3.1.1. Restriction of XQuery to XPath

Features of XQuery beyond those of XPath include:

- XQuery expressions can construct and return new XML nodes, in addition to all possible XPath values. XPath can create and return values of the atomic types (numbers, strings, and so on) but can only return XML nodes that were already present in documents supplied as input to the expression.
- XQuery has control constructs for iteration, sorting, and grouping.
- XQuery allows declaration and use of local functions.

Recent XPath versions begin to offer capabilities overlapping with these (such as functional-style `for-each` and `sort`, anonymous functions, and `parse-xml` to create a node from a string), but such features were not available before XPath 3.0.

#### D.3.1.2. Restriction of XPath to 1.0

For developers familiar with XQuery and XPath 2.0 or later, XPath 1.0 presents a number of differences to contend with:

- The fundamental type of an XQuery/XPath expression, the `sequence`, which can contain XML nodes, atomic values, or both, does not exist in XPath 1.0. A 1.0 expression can only produce a node-set (containing zero or more XML nodes), or a single atomic value.
- Unlike an XQuery/XPath sequence, which can contain any desired items in any desired order, an XPath 1.0 node-set has no guaranteed order and, like any set, does not allow multiple appearances of the same item.

**Note**

The libxml2 library does seem to always return node-sets to Postgres Pro with their members in the same relative order they had in the input document. Its documentation does not commit to this behavior, and an XPath 1.0 expression cannot control it.

- While XQuery/XPath provides all of the types defined in XML Schema and many operators and functions over those types, XPath 1.0 has only node-sets and the three atomic types `boolean`, `double`, and `string`.
- XPath 1.0 has no conditional operator. An XQuery/XPath expression such as `if ( hat ) then hat / @size else "no hat"` has no XPath 1.0 equivalent.
- XPath 1.0 has no ordering comparison operator for strings. Both `"cat" < "dog"` and `"cat" > "dog"` are false, because each is a numeric comparison of two NaNs. In contrast, `=` and `!=` do compare the strings as strings.
- XPath 1.0 blurs the distinction between *value comparisons* and *general comparisons* as XQuery/XPath define them. Both `sale/@hatsize = 7` and `sale/@customer = "alice"` are existentially quantified comparisons, true if there is any `sale` with the given value for the attribute, but `sale/@taxable = false()` is a value comparison to the *effective boolean value* of a whole node-set. It is true only if no `sale` has a `taxable` attribute at all.
- In the XQuery/XPath data model, a *document node* can have either document form (i.e., exactly one top-level element, with only comments and processing instructions outside of it) or content form (with those constraints relaxed). Its equivalent in XPath 1.0, the *root node*, can only be in document form. This is part of the reason an `xml` value passed as the context item to any Postgres Pro XPath-based function must be in document form.

The differences highlighted here are not all of them. In XQuery and the 2.0 and later versions of XPath, there is an XPath 1.0 compatibility mode, and the W3C lists of [function library changes](#) and [language changes](#) applied in that mode offer a more complete (but still not exhaustive) account of the differences. The compatibility mode cannot make the later languages exactly equivalent to XPath 1.0.

**D.3.1.3. Mappings between SQL and XML Data Types and Values**

In SQL:2006 and later, both directions of conversion between standard SQL data types and the XML Schema types are specified precisely. However, the rules are expressed using the types and semantics of XQuery/XPath, and have no direct application to the different data model of XPath 1.0.

When Postgres Pro maps SQL data values to XML (as in `xmlelement`), or XML to SQL (as in the output columns of `xmltable`), except for a few cases treated specially, Postgres Pro simply assumes that the XML data type's XPath 1.0 string form will be valid as the text-input form of the SQL datatype, and conversely. This rule has the virtue of simplicity while producing, for many data types, results similar to the mappings specified in the standard.

Where interoperability with other systems is a concern, for some data types, it may be necessary to use data type formatting functions (such as those in [Section 9.8](#)) explicitly to produce the standard mappings.

**D.3.2. Incidental Limits of the Implementation**

This section concerns limits that are not inherent in the libxml2 library, but apply to the current implementation in Postgres Pro.

**D.3.2.1. Only BY VALUE Passing Mechanism Is Supported**

The SQL standard defines two *passing mechanisms* that apply when passing an XML argument from SQL to an XML function or receiving a result: `BY REF`, in which a particular XML value retains its node identity, and `BY VALUE`, in which the content of the XML is passed but node identity is not preserved.

A mechanism can be specified before a list of parameters, as the default mechanism for all of them, or after any parameter, to override the default.

To illustrate the difference, if *x* is an XML value, these two queries in an SQL:2006 environment would produce true and false, respectively:

```
SELECT XMLQUERY('$a is $b' PASSING BY REF x AS a, x AS b NULL ON EMPTY);
SELECT XMLQUERY('$a is $b' PASSING BY VALUE x AS a, x AS b NULL ON EMPTY);
```

Postgres Pro will accept `BY VALUE` or `BY REF` in an `XML EXISTS` or `XMLTABLE` construct, but it ignores them. The `xml` data type holds a character-string serialized representation, so there is no node identity to preserve, and passing is always effectively `BY VALUE`.

### **D.3.2.2. Cannot Pass Named Parameters to Queries**

The XPath-based functions support passing one parameter to serve as the XPath expression's context item, but do not support passing additional values to be available to the expression as named parameters.

### **D.3.2.3. No XML (SEQUENCE) Type**

The Postgres Pro `xml` data type can only hold a value in `DOCUMENT` or `CONTENT` form. An XQuery/XPath expression context item must be a single XML node or atomic value, but XPath 1.0 further restricts it to be only an XML node, and has no node type allowing `CONTENT`. The upshot is that a well-formed `DOCUMENT` is the only form of XML value that Postgres Pro can supply as an XPath context item.

---

# Appendix E. Release Notes

The release notes contain the significant changes in each Postgres Pro Standard release, with major features and migration issues listed at the top. The release notes do not contain changes that affect only a few users or changes that are internal and therefore not user-visible. For example, the optimizer is improved in almost every release, but the improvements are usually observed by users as simply faster queries.

## E.1. Postgres Pro Standard 13.7.2

**Release Date:** 2022-06-08

### E.1.1. Overview

This release is based on PostgreSQL 13.7 and Postgres Pro Standard 13.7.1. All improvements inherited from PostgreSQL 13.7 are listed in [PostgreSQL 13.7 Release Notes](#). Other major changes and enhancements are as follows:

- Changed the algorithm of composite type name generation. This fixes an issue in the code of vanilla PostgreSQL, which strictly limits the number of tables with the same long prefix in names.
- Upgraded [pg\\_probackup](#) to version 2.5.6, which provides the following new features and bugfixes as compared to version 2.5.5:
  - Added the `--dry-run` flag to the `catchup` command to allow you to estimate the size of data files to be transferred, but make no changes on disk.
  - Changed the level of detail of logging some `catchup` messages for user convenience of log reading.
  - Fixed a bug that prevented correct rereading of a block after a message “File: ... blknum ... have wrong checksum, try again” was issued.

### E.1.2. Migration to Version 13.7.2

If you are upgrading from Postgres Pro Standard based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

When upgrading from Postgres Pro versions 13.2.1 or lower, rebuild indexes containing at least one included column of type for which the collation was defined in the table.

If you are upgrading from Postgres Pro versions 13.2.2 or lower and take PTRACK backups using `pg_probackup`, retake a full backup after upgrade.

To migrate from PostgreSQL or a Postgres Pro Standard release based on a previous PostgreSQL major version, see the instructions in [Postgres Pro Standard 13.1.1 Release Notes](#).

## E.2. Postgres Pro Standard 13.7.1

**Release Date:** 2022-05-26

### E.2.1. Overview

This release is based on PostgreSQL 13.7 and Postgres Pro Standard 13.6.1. All improvements inherited from PostgreSQL 13.7 are listed in [PostgreSQL 13.7 Release Notes](#). Other major changes and enhancements are as follows:

- Ended support for Ubuntu 21.04 and added support for Ubuntu 22.04.
- Ended support for OSnova 2.0.
- Ended support for GosLinux 7.
- Upgraded [mamonsu](#) to version 3.4.0. Notable changes are as follows:

- Added a new `timeout` parameter to the `[zabbix]` section of the `mamonsu` configuration file. It allows you to set maximum time to wait while connecting to the Zabbix server.
- Added a new `mamonsu dashboard upload template_name` command, which can be used to upload a Zabbix dashboard with the `mamonsu` metrics to a template on the Zabbix server version 6.0 or higher.
- Upgraded [PTRACK](#) to version 2.3.0, optimizing PTRACK map loading, which previously in some cases could considerably slow down overall database loading. A substantial speed-up is observed for large-size maps.
- Upgraded [pgpro\\_stats](#) to version 1.4, which provides the following new features and bugfixes:
  - Added `pgpro_stats_vacuum_tables` and `pgpro_stats_vacuum_indexes` views, which show statistics about vacuuming tables and indexes, respectively. Functions with the same names, which define these views for any specified database and table/index, are also added and can return statistics about vacuuming all tables/indexes in the specified database too.
  - Fixed a bug in extra shared memory allocation. The size of this memory was calculated with an error, which could cause memory corruption, incorrect computation of statistics or even a server crash.
  - Fixed an issue that caused a server crash when queries that only differ in constants contained in the query text were sent one after another through the extended query protocol.
- Upgraded [pgpro\\_pwr](#) to version 3.9, which provides the following new features and bugfixes:
  - Added statistics on invalidation messages and on vacuuming tables and indexes to the report.
  - Optimized retention handling for obsolete dictionary entries in the `pgpro_pwr` historical repository.
  - Fixed the type of value in calculating the wait time while taking a sample. This prevents a yet unlikely integer overflow error.

## E.2.2. Migration to Version 13.7.1

If you are upgrading from Postgres Pro Standard based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

When upgrading from Postgres Pro versions 13.2.1 or lower, rebuild indexes containing at least one included column of type for which the collation was defined in the table.

If you are upgrading from Postgres Pro versions 13.2.2 or lower and take PTRACK backups using `pg_probackup`, retake a full backup after upgrade.

To migrate from PostgreSQL or a Postgres Pro Standard release based on a previous PostgreSQL major version, see the instructions in [Postgres Pro Standard 13.1.1 Release Notes](#).

## E.3. Postgres Pro Standard 13.6.1

**Release Date:** 2022-02-25

### E.3.1. Overview

This release is based on PostgreSQL 13.6 and Postgres Pro Standard 13.5.1. All improvements inherited from PostgreSQL 13.6 are listed in [PostgreSQL 13.6 Release Notes](#). Other major changes and enhancements are as follows:

- Increased the number of partitions of the shared buffer mapping hash table to 1024, which can improve performance on multi-core systems.
- Fixed the use of multi-column statistics by planner. Previously, when the optimizer estimated the query selectivity using multi-column statistics and the query conditions only included part of the columns involved, the cardinality could be considerably overestimated, so the created plan would be non-optimal.

- Fixed the out-of-memory (OOM) killer settings in system startup files. Previously the OOM score adjustment value was set for all Postgres Pro processes rather than for postmaster only, so when Postgres Pro exhausted all RAM, the OOM killer could start killing irrelevant processes, such as `sshd`.
- Added support for Rocky Linux 8.
- Ended support for outdated operating systems Debian 8, Astra Linux Smolensk 1.5 and MSVSphere 6.3.
- Upgraded [pg\\_probackup](#) to version 2.5.5, which provides the following new features and bugfixes as compared to the previous included version 2.5.3:
  - Added the `--checkunique` option to the `checkdb` command to work together with `--amcheck` and verify unique constraints during logical verification of indexes when the `amcheck` extension is installed in the database and its version supports the verification of unique constraints. Check the [amcheck](#) documentation for whether this verification is supported.
  - Fixed an issue that could occur when the source database was not on the timeline 1 and the destination database did not fall behind: `probackup` sanity checks on `catchup` timeline history failed with the error “Destination is not in source timeline history”.
  - Fixed the behavior of `catchup` in `DELTA` and `PTRACK` modes. The fixed issue could occur when `pg_probackup` operated remotely via SSH and `--destination-pgdata` was the same as `--source-pgdata`, caused corruption of the source instance (at least the `global/pg_control`, `global/pg_filenode.map` and `base/*/pg_filenode.map` files got deleted) and resulted in the error “Could not open file `"/pgwal/test/global/pg_control"` for reading: No such file or directory”.

### E.3.2. Migration to Version 13.6.1

If you are upgrading from Postgres Pro Standard based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

When upgrading from Postgres Pro versions 13.2.1 or lower, rebuild indexes containing at least one included column of type for which the collation was defined in the table.

If you are upgrading from Postgres Pro versions 13.2.2 or lower and take `PTRACK` backups using `pg_probackup`, retake a full backup after upgrade.

To migrate from PostgreSQL or a Postgres Pro Standard release based on a previous PostgreSQL major version, see the instructions in [Postgres Pro Standard 13.1.1 Release Notes](#).

## E.4. Postgres Pro Standard 13.5.1

**Release Date:** 2021-11-26

### E.4.1. Overview

This release is based on PostgreSQL 13.5 and Postgres Pro Standard 13.4.1. All improvements inherited from PostgreSQL 13.5 are listed in [PostgreSQL 13.5 Release Notes](#). Other major changes and enhancements are as follows:

- Dropped support for the [sr\\_plan](#) extension.
- Upgraded [mamonsu](#) to version 3.1.0. Notable changes are as follows:
  - A new option for `bootstrap` is added. With this option, if `-dbname` is not explicitly specified, its value will be automatically set to the database name defined in the `[postgres]` section of the `mamonsu` configuration file.
  - A critical issue is fixed that could arise when the `bootstrap` step was skipped. In this case, although a user can work with `mamonsu` under superuser permissions, the special `mamonsu` schema is not created, but after creating the auxiliary extension [pg\\_buffercache](#) in any other

schema, running `mamonsu` resulted in errors “`ERROR: relation "mamonsu.pg_buffercache" does not exist...`”.

- Added support for ALT Linux 10.
- Changed the minimum supported Windows versions to Windows 10 and Windows Server 2012 R2.
- Ended support for Ubuntu 20.10 and added support for Ubuntu 21.10.
- Fixed a [pg\\_probackup](#) issue with archiving WAL from a directory outside of the data directory. Previously, multi-threaded and batch optimizations of `archive-push` prevented such archiving; now it is possible to archive WAL from any directory, but if it is outside of the data directory, multi-threaded and batch optimizations are automatically turned off.
- Fixed [pg\\_dumpall](#) to avoid using an insecure search path.
- Upgraded [pgpro\\_pwr](#). Major enhancements are as follows:
  - Added the “Load distribution” section to the report, which shows load distribution of different resources (for example, total time or shared blocks written) for heavily loaded objects, such as databases, applications, hosts, or users, in graphics, as stacked bar charts.
  - Added the “Session statistics by database” and “WAL statistics” report tables, based on new views and fields made available in Postgres Pro 14.
- Deprecated [WAITLSN](#) command.

## E.4.2. Migration to Version 13.5.1

If you are upgrading from Postgres Pro Standard based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

When upgrading from Postgres Pro versions 13.2.1 or lower, rebuild indexes containing at least one included column of type for which the collation was defined in the table.

If you are upgrading from Postgres Pro versions 13.2.2 or lower and take PTRACK backups using `pg_probackup`, retake a full backup after upgrade.

To migrate from PostgreSQL or a Postgres Pro Standard release based on a previous PostgreSQL major version, see the instructions in [Postgres Pro Standard 13.1.1 Release Notes](#).

## E.5. Postgres Pro Standard 13.4.1

**Release Date:** 2021-08-26

### E.5.1. Overview

This release is based on PostgreSQL 13.4 and Postgres Pro Standard 13.3.1. All improvements inherited from PostgreSQL 13.4 are listed in [PostgreSQL 13.4 Release Notes](#). Other major changes and enhancements are as follows:

- Added support for Debian 11.
- Upgraded `mamonsu` to version 3.0, which is incompatible with the previous one. Read [mamonsu Compatibility Considerations](#) to learn what you need to do to continue using the application.
- Added support for Red OS Murom 7.3.
- Added support for Astra Linux Smolensk 1.7.
- Fixed the behavior of `ALTER TABLE IF EXISTS table RENAME TO table1` command in the case when the source table is missing and the `pg_pathman` extension was loaded. Previously, `ERROR` was returned, and now `NOTICE` is generated, which is how Postgres Pro behaves with no `pg_pathman` extension loaded.
- Upgraded [pg\\_probackup](#) to version 2.5.1, which added a new `catchup` command to copy a Postgres Pro instance directly, without using the backup catalog. This allows you to add a new standby server in a parallel mode or to have a fallen-behind standby server “catch up” with master.

- Fixed a bug in the query optimizer, which overestimated the cost of index scan using a unique index. This behavior was observed when between index scans using a unique index and using a non-unique one, the non-unique index was chosen, which resulted in excessive disk accesses and a considerable overall slowdown.

## E.5.2. Migration to Version 13.4.1

If you are upgrading from Postgres Pro Standard based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

When upgrading from Postgres Pro versions 13.2.1 or lower, rebuild indexes containing at least one included column of type for which the collation was defined in the table.

If you are upgrading from Postgres Pro versions 13.2.2 or lower and take PTRACK backups using `pg_probackup`, retake a full backup after upgrade.

To migrate from PostgreSQL or a Postgres Pro Standard release based on a previous PostgreSQL major version, see the instructions in [Postgres Pro Standard 13.1.1 Release Notes](#).

## E.6. Postgres Pro Standard 13.3.1

**Release Date:** 2021-05-28

### E.6.1. Overview

This release is based on PostgreSQL 13.3 and Postgres Pro Standard 13.2.2. All improvements inherited from PostgreSQL 13.3 are listed in [PostgreSQL 13.3 Release Notes](#). Other major changes and enhancements are as follows:

- Upgraded [PTRACK](#) to use a different algorithm for tracking changed pages. This greatly reduces the number of false positives among the changed pages tracked in the PTRACK map and hence the size of PTRACK backups.
- Fixed a bug that caused queries to fail with an error “geqo failed to make a valid plan” after updating statistics with `VACUUM ANALYZE` when `enable_compound_index_stats` was on.
- Ended support for Ubuntu 16.04 and added support for Ubuntu 21.04.
- Fixed an issue of installing Postgres Pro on Alt Linux 8.2 SP. For this OS, Postgres Pro now provides a separate package repository, which is different from the repositories of earlier Alt Linux SP versions.
- Improved the planner's algorithm of self-join selectivity calculation, which ensures more accurate estimates of the number of rows after joins.
- Upgraded [mamonsu](#) to version 2.7.1.
- Upgraded [pgpro\\_controldata](#) to version 13.2.0.
- On Windows systems, fixed an issue with updating temporary files for statistics if they are currently in use.

### E.6.2. Migration to Version 13.3.1

If you are upgrading from Postgres Pro Standard based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

When upgrading from Postgres Pro versions 13.2.1 or lower, rebuild indexes containing at least one included column of type for which the collation was defined in the table.

If you are upgrading from Postgres Pro versions 13.2.2 or lower and take PTRACK backups using `pg_probackup`, retake a full backup after upgrade.

To migrate from PostgreSQL or a Postgres Pro Standard release based on a previous PostgreSQL major version, see the instructions in [Postgres Pro Standard 13.1.1 Release Notes](#).

## E.7. Postgres Pro Standard 13.2.2

**Release Date:** 2021-04-02

### E.7.1. Overview

This release is based on PostgreSQL 13.2 and Postgres Pro Standard 13.2.1. All improvements inherited from PostgreSQL 13.2 are listed in [PostgreSQL 13.2 Release Notes](#). Other major changes and enhancements are as follows:

- Fixed the signed integer overflow in `ptrack` that could occur when `ptrack` map data in RAM was saved to disk. Previously, for large-size `ptrack` maps (`ptrack.mapsize > 17200 MB`), this resulted in a “FATAL/ERROR `ptrack checkpoint: stat_buf.st_size != ptrack_map_size XXX != YYY`” error during a checkpoint.
- Fixed building of covering indexes with included columns of type for which the collation is defined in the table. The fixed defect could result in an “ERROR: could not determine which collation to use for string comparison” error during the `ANALYZE` operation on the table, although single columns could be successfully analyzed. To avoid this error in future, after upgrading, rebuild indexes containing at least one included column of such types.

### E.7.2. Migration to Version 13.2.2

If you are upgrading from Postgres Pro Standard based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

When upgrading from Postgres Pro versions 13.2.1 or lower, rebuild indexes containing at least one included column of type for which the collation was defined in the table.

To migrate from PostgreSQL or a Postgres Pro Standard release based on a previous PostgreSQL major version, see the instructions in [Postgres Pro Standard 13.1.1 Release Notes](#).

## E.8. Postgres Pro Standard 13.2.1

**Release Date:** 2021-03-04

### E.8.1. Overview

This release is based on PostgreSQL 13.2 and Postgres Pro Standard 13.1.1. All improvements inherited from PostgreSQL 13.2 are listed in [PostgreSQL 13.2 Release Notes](#). Other major changes and enhancements are as follows:

- Upgraded `pgpro_pwr`. Major enhancements are as follows:
  - Added export and import functionalities.
  - The collection of relation sizes is now manageable, so that collecting them rarely is possible.
  - Functions support server descriptions.
  - Reporting now supports `pg_stat_kcache 2.2.0` and provides more resource usage statistics.
- Upgraded `pg_probackup` to the latest version 2.4.10. Major improvements over the previously included version 2.4.2 are as follows:
  - Incremental restore with `--force` flag now allows you to overwrite the contents of the directory specified by `PGDATA` in case of system ID mismatch. Previously this resulted in an error.
  - It is now possible to restore and validate backups from a read-only filesystem.
  - In-place merge is now disabled only if the storage format changed.
  - Non-exclusive backup locks are implemented, which enables concurrent validate and restore. Backup shared locks are now released at the process exit.

- Streamed WAL segments are now added to the backup filelist on the fly and fsynced to disk at the end of the backup.

See [pg\\_probackup documentation](#) for details.

- Fixed a bug that prevented setting `ptrack.map_size` to values higher than 1024 MB due to `int32` overflow. See [PTRACK](#) for details.
- Added [pgpro\\_controldata](#) utility to display control information of a PostgreSQL/Postgres Pro database cluster and compatibility information for a cluster and/or server.
- Added the `pg_snapshot_any` function to help superusers explore corrupted databases. See [Section 9.27.11](#) for details.
- Upgraded [pgpro\\_stats](#). Now it shows resource usage statistics of statement planning and execution, as well as cache invalidation metrics.

## E.8.2. Migration to Version 13.2.1

If you are upgrading from Postgres Pro Standard based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

To migrate from PostgreSQL or a Postgres Pro Standard release based on a previous PostgreSQL major version, see the instructions in [Postgres Pro Standard 13.1.1 Release Notes](#).

## E.9. Postgres Pro Standard 13.1.1

**Release Date:** 2020-12-17

### E.9.1. Overview

This release is based on PostgreSQL 13.1 and includes all the new features introduced in PostgreSQL 13, as well as bug fixes implemented in PostgreSQL 13.1. For their detailed description, see [PostgreSQL 13 Release Notes](#) and [PostgreSQL 13.1 Release Notes](#), respectively. Other major changes and enhancements are as follows:

- Added [pgpro\\_pwr](#) extension. It enables you to generate workload reports, which help to discover most resource-intensive activities in your database.
- Added [pgpro\\_stats](#) to Postgres Pro Standard. This extension combines tracking execution statistics of SQL statements and calculating wait event statistics.
- Added support for OSnova 2.0. This is the first major release to support this OS family.
- Upgraded [mchar](#) to version 2.2. See [Section E.9.2](#) for related upgrade instructions.

For the list of extension modules and utilities specific to Postgres Pro Standard, as well as the main user-visible core changes as compared to vanilla PostgreSQL, see [Section 2](#).

### E.9.2. Migration to Version 13

To migrate from PostgreSQL or a Postgres Pro Standard release based on a previous PostgreSQL major version, make sure to install its latest available minor version and then perform a dump/restore using [pg\\_dumpall](#) or use the [pg\\_upgrade](#) utility:

- If you choose to run `pg_upgrade`, make sure to initialize the new database cluster with compatible parameters. In particular, pay attention to the provider of the default collation and the [checksum](#) settings in the cluster you are migrating from. If `pg_upgrade` creates any SQL files in its current directory, run these files to complete the upgrade.
- If you are opting for a dump/restore, do not forget to use the `--add-collprovider` option to correctly choose the provider for the default collation of the migrated database.

To find out the default collation and its provider in the original cluster, see the `datcollate` value for the `template0` database in the [pg\\_database](#) catalog. If you are upgrading from a version where provider of

the default collation is not specified, use `libc` provider if upgrading from vanilla PostgreSQL, and omit the provider if upgrading from earlier versions of Postgres Pro.

Besides, note the following collation-related upgrade specifics described below.

On Windows, Postgres Pro Standard installations could contain databases with default collations provided by ICU, where the name of the database default collation used a syntactically correct BCP 47 language tag format, but had a wrong language code or other parameters, which invalidated the database default collation name for ICU.

If this issue affects the `template0` database, you will get the following error message when trying to initialize the cluster with the same collation: `failed to get the canonical name for collation locale`. In this case, you can only use `dump/restore` for upgrade, specifying a valid locale for the selected collation provider.

If this issue affects other databases, you will get the same error message when Postgres Pro tries to create these databases with invalid collation in the new cluster. In this case, you can try the following:

1. Make a dump of the database using `pg_dump`; it is required to use `--create` and `--format=plain` options.
2. Change the provider for the default collation of the database in the dump file from `'@icu'` to `'@libc'`.
3. In `psql`, restore the modified dump to complete the upgrade. This operation may fail if any constraints depending on the database collations are violated. In this case, you can try resolving the issues manually.

In some corner cases, using `dump/restore` could lead to invalid constraints in the restored databases, so you should use `pg_upgrade`. For example:

- If the installation of Postgres Pro Standard 9.6 or lower contained any indexes or constraints depending on collations other than the default collation of the database, `C`, or `POSIX` in databases with multibyte encodings, indexes and constraints in such databases could become inconsistent when these databases are migrated to Postgres Pro 10 or higher. On Windows, this situation can also happen if the database with a multibyte encoding contained any indexes or constraints depending on the default collation with a verbose name, such as `"Russian_Russia[.encoding]"` or `"English_United States[.encoding]"`.
- For upgrades from Postgres Pro Standard 10, if the cluster has no information about the ICU library version, the ICU collation versions are checked to ensure that indexes and constraints remain valid after the upgrade. However, for clusters that contain databases with default ICU collations but have no information about the ICU library version and/or its collation versions, it is impossible to check that the current version of Postgres Pro uses the same version of the ICU library.
- On Windows, in Postgres Pro Standard 10 clusters with default collations provided by ICU, the ICU collation locale may not match the corresponding `libc` collation locale.

If you use `pg_upgrade`, it declares such indexes and constraints invalid and creates `reindex_text_indexes.sql` and `validate_text_constraints.sql`, respectively. You have to run these files to complete the upgrade.

### Note

To avoid conflicts on Linux systems, do not use the `postgrespro-std-13` package to install the new Postgres Pro binaries. Use the individual packages instead. In this case, server `autostart` needs to be enabled manually, if required. For details on the available packages, see [Chapter 16](#).

If you used `mchar`, to ensure acceleration of the `LIKE` operator after upgrading from previous versions of Postgres Pro, run:

```
ALTER EXTENSION mchar UPDATE;
```

For upgrade requirements imposed by vanilla PostgreSQL, see [Section E.17](#).

## E.10. Release 13.7

**Release date:** 2022-05-12

This release contains a variety of fixes from 13.6. For information about new features in major release 13, see [Section E.17](#).

### E.10.1. Migration to Version 13.7

A dump/restore is not required for those running 13.X.

However, if you have any GiST indexes on columns of type `ltree` (supplied by the `contrib/ltree` extension), you should re-index them after updating. See the second changelog entry below.

Also, if you are upgrading from a version earlier than 13.6, see [Section E.11](#).

### E.10.2. Changes

- Confine additional operations within “security restricted operation” sandboxes (Sergey Shinderuk, Noah Misch)

Autovacuum, `CLUSTER`, `CREATE INDEX`, `REINDEX`, `REFRESH MATERIALIZED VIEW`, and `pg_amcheck` activated the “security restricted operation” protection mechanism too late, or even not at all in some code paths. A user having permission to create non-temporary objects within a database could define an object that would execute arbitrary SQL code with superuser permissions the next time that autovacuum processed the object, or that some superuser ran one of the affected commands against it.

The PostgreSQL Project thanks Alexander Lakhin for reporting this problem. (CVE-2022-1552)

- Fix default signature length for `gist_ltree_ops` indexes (Tomas Vondra, Alexander Korotkov)

The default signature length (hash size) for GiST indexes on `ltree` columns was accidentally changed while upgrading that operator class to support operator class parameters. If any operations had been done on such an index without first upgrading the `ltree` extension to version 1.2, they were done assuming that the signature length was 28 bytes rather than the intended 8. This means it is very likely that such indexes are now corrupt. For safety we recommend re-indexing all GiST indexes on `ltree` columns after installing this update. (Note that GiST indexes on `ltree[]` columns, that is arrays of `ltree`, are not affected.)

- Stop using query-provided column aliases for the columns of whole-row variables that refer to plain tables (Tom Lane)

The column names in tuples produced by a whole-row variable (such as `tbl.*` in contexts other than the top level of a `SELECT` list) are now always those of the associated named composite type, if there is one. We'd previously attempted to make them track any column aliases that had been applied to the `FROM` entry the variable refers to. But that's semantically dubious, because really then the output of the variable is not at all of the composite type it claims to be. Previous attempts to deal with that inconsistency had bad results up to and including storing unreadable data on disk, so just give up on the whole idea.

In cases where it's important to be able to relabel such columns, a workaround is to introduce an extra level of sub-`SELECT`, so that the whole-row variable is referring to the sub-`SELECT`'s output and not to a plain table. Then the variable is of type `record` to begin with and there's no issue.

- Fix incorrect output for types `timestamptz` and `timetz` in `table_to_xmlschema()` and allied functions (Renan Soares Lopes)

The `xmlschema` output for these types included a malformed regular expression.

- Avoid core dump in parser for a `VALUES` clause with zero columns (Tom Lane)

- Fix planner errors for `GROUPING()` constructs that reference outer query levels (Richard Guo, Tom Lane)
- Fix plan generation for index-only scans on indexes with both returnable and non-returnable columns (Tom Lane)

The previous coding could try to read non-returnable columns in addition to the returnable ones. This was fairly harmless because it didn't actually do anything with the bogus values, but it fell foul of a recently-added error check that rejected such a plan.

- Avoid accessing a no-longer-pinned shared buffer while attempting to lock an outdated tuple during `EvalPlanQual` (Tom Lane)

The code would touch the buffer a couple more times after releasing its pin. In theory another process could recycle the buffer (or more likely, try to defragment its free space) as soon as the pin is gone, probably leading to failure to find the newer version of the tuple.

- Fix query-lifespan memory leak in an `IndexScan` node that is performing reordering (Aliaksandr Kalenik)
- Fix `ALTER FUNCTION` to support changing a function's parallelism property and its `SET`-variable list in the same command (Tom Lane)

The parallelism property change was lost if the same command also updated the function's `SET` clause.

- Fix bogus errors from attempts to alter system columns of tables (Tom Lane)

The system should just tell you that you can't do it, but sometimes it would report “no owned sequence found” instead.

- Fix mis-sorting of table rows when `CLUSTERING` using an index whose leading key is an expression (Peter Geoghegan, Thomas Munro)

The table would be rebuilt with the correct data, but in an order having little to do with the index order.

- Fix risk of deadlock failures while dropping a partitioned index (Jimmy Yih, Gaurab Dey, Tom Lane)

Ensure that the required table and index locks are taken in the standard order (parents before children, tables before indexes). The previous coding for `DROP INDEX` did it differently, and so could deadlock against concurrent queries taking these locks in the standard order.

- Fix race condition between `DROP TABLESPACE` and checkpointing (Nathan Bossart)

The checkpoint forced by `DROP TABLESPACE` could sometimes fail to remove all dead files from the tablespace's directory, leading to a bogus “tablespace is not empty” error.

- Fix possible trouble in crash recovery after a `TRUNCATE` command that overlaps a checkpoint (Kyotaro Horiguchi, Heikki Linnakangas, Robert Haas)

`TRUNCATE` must ensure that the table's disk file is truncated before the checkpoint is allowed to complete. Otherwise, replay starting from that checkpoint might find unexpected data in the supposedly-removed pages, possibly causing replay failure.

- Fix unsafe toast-data accesses during temporary object cleanup (Andres Freund)

Temporary-object deletion during server process exit could fail with “FATAL: cannot fetch toast data without an active snapshot”. This was usually harmless since the next use of that temporary schema would clean up successfully.

- Improve wait logic in `RegisterSyncRequest` (Thomas Munro)

If we run out of space in the checkpointer sync request queue (which is hopefully rare on real systems, but is common when testing with a very small buffer pool), we wait for it to drain. While waiting, we should report that as a wait event so that users know what is going on, and also watch

for postmaster death, since otherwise the loop might never terminate if the checkpoint has already exited.

- Fix “PANIC: xlog flush request is not satisfied” failure during standby promotion when there is a missing WAL continuation record (Sami Imseih)
- Fix possibility of self-deadlock in hot standby conflict handling (Andres Freund)

With unlucky timing, the WAL-applying process could get stuck while waiting for some other process to release a buffer lock.

- Fix possible mis-identification of the correct ancestor relation to publish logical replication changes through (Tomas Vondra, Hou zj, Amit Kapila)

If `publish_via_partition_root` is enabled, and there are multiple publications naming different ancestors of the currently-modified relation, the wrong ancestor might be chosen for reporting the change.

- Ensure that logical replication apply workers can be restarted even when we're up against the `max_sync_workers_per_subscription` limit (Amit Kapila)

Faulty coding of the limit check caused a restarted worker to exit immediately, leaving fewer workers than there should be.

- Include unchanged replica identity key columns in the WAL log for an update, if they are stored out-of-line (Dilip Kumar, Amit Kapila)

Otherwise subscribers cannot see the values and will fail to replicate the update.

- Cope correctly with platforms that have no support for altering the server process's display in `ps(1)` (Andrew Dunstan)

Few platforms are like this (the only supported one is Cygwin), so we'd managed not to notice that refactoring introduced a potential memory clobber.

- Disallow execution of SPI functions during PL/Perl function compilation (Tom Lane)

Perl can be convinced to execute user-defined code during compilation of a PL/Perl function. However, it's not okay for such code to try to invoke SQL operations via SPI. That results in a crash, and if it didn't crash it would be a security hazard, because we really don't want code execution during function validation. Put in a check to give a friendlier error message instead.

- Make libpq accept root-owned SSL private key files (David Steele)

This change synchronizes libpq's rules for safe ownership and permissions of SSL key files with the rules the server has used since release 9.6. Namely, in addition to the current rules, allow the case where the key file is owned by root and has permissions `rw-r-----` or less. This is helpful for system-wide management of key files.

- Fix behavior of libpq's `PQisBusy()` function after a connection failure (Tom Lane)

If we'd detected a write failure, `PQisBusy()` would always return true, which is the wrong thing: we want input processing to carry on normally until we've read whatever is available from the server. The practical effect of this error is that applications using libpq's async-query API would typically detect connection loss only when `PQconsumeInput()` returns a hard failure. With this fix, a connection loss will normally be reported via an error `PGresult` object, which is a much cleaner behavior for most applications.

- Make `pg_ctl` recheck postmaster aliveness while waiting for stop/restart/promote actions (Tom Lane)

`pg_ctl` would verify that the postmaster is alive as a side-effect of sending the stop or promote signal, but then it just naively waited to see the on-disk state change. If the postmaster died uncleanly without having removed its PID file or updated the control file, `pg_ctl` would wait until timeout. Instead make it recheck every so often that the postmaster process is still there.

- Fix error handling in `pg_waldump` (Kyotaro Horiguchi, Andres Freund)

While trying to read a WAL file to determine the WAL segment size, `pg_waldump` would report an incorrect error for the case of a too-short file. In addition, the file name reported in this and related error messages could be garbage.

- Ensure that `contrib/pageinspect` functions cope with all-zero pages (Michael Paquier)

This is a legitimate edge case, but the module was mostly unprepared for it. Arrange to return nulls, or no rows, as appropriate; that seems more useful than raising an error.

- In `contrib/pageinspect`, add defenses against incorrect page “special space” contents, tighten checks for correct page size, and add some missing checks that an index is of the expected type (Michael Paquier, Justin Pryzby, Julien Rouhaud)

These changes make it less likely that the module will crash on bad data.

- In `contrib/postgres_fdw`, verify that `ORDER BY` clauses are safe to ship before requesting a remotely-ordered query, and include a `USING` clause if necessary (Ronan Dunklau)

This fix prevents situations where the remote server might sort in a different order than we intend. While sometimes that would be only cosmetic, it could produce thoroughly wrong results if the remote data is used as input for a locally-performed merge join.

- Update JIT code to work with LLVM 14 (Thomas Munro)
- Clean up assorted failures under clang's `-fsanitize=undefined` checks (Tom Lane, Andres Freund, Zhihong Yu)

Most of these changes are just for pro-forma compliance with the letter of the C and POSIX standards, and are unlikely to have any effect on production builds.

- Fix PL/Perl so it builds on C compilers that don't support statements nested within expressions (Tom Lane)

- Fix possible build failure of `pg_dumpall` on Windows, when not using MSVC to build (Andres Freund)
- In Windows builds, use `gendef` instead of `pexports` to build DEF files (Andrew Dunstan)

This adapts the build process to work on recent MSys tool chains.

- Prevent extra expansion of shell wildcard patterns in programs built under MinGW (Andrew Dunstan)

For some reason the C library provided by MinGW will expand shell wildcard characters in a program's command-line arguments by default. This is confusing, not least because it doesn't happen under MSVC, so turn it off.

- Update time zone data files to tzdata release 2022a for DST law changes in Palestine, plus historical corrections for Chile and Ukraine.

## E.11. Release 13.6

**Release date:** 2022-02-10

This release contains a variety of fixes from 13.5. For information about new features in major release 13, see [Section E.17](#).

### E.11.1. Migration to Version 13.6

A dump/restore is not required for those running 13.X.

However, if you have applied `REINDEX CONCURRENTLY` to a TOAST table's index, or observe failures to access TOAST datums, see the first changelog entry below.

Also, if you are upgrading from a version earlier than 13.5, see [Section E.12](#).

## E.11.2. Changes

- Enforce standard locking protocol for TOAST table updates, to prevent problems with `REINDEX CONCURRENTLY` (Michael Paquier)

If applied to a TOAST table or TOAST table's index, `REINDEX CONCURRENTLY` tended to produce a corrupted index. This happened because sessions updating TOAST entries released their `ROW EXCLUSIVE` locks immediately, rather than holding them until transaction commit as all other updates do. The fix is to make TOAST updates hold the table lock according to the normal rule. Any existing corrupted indexes can be repaired by reindexing again.

- Avoid null-pointer crash in `ALTER STATISTICS` when the statistics object is dropped concurrently (Tomas Vondra)
- Fix incorrect plan creation for parallel single-child Append nodes (David Rowley)

In some cases the Append would be simplified away when it should not be, leading to wrong query results (duplicated rows).

- Fix index-only scan plans for cases where not all index columns can be returned (Tom Lane)

If an index has both returnable and non-returnable columns, and one of the non-returnable columns is an expression using a table column that appears in a returnable index column, then a query using that expression could result in an index-only scan plan that attempts to read the non-returnable column, instead of recomputing the expression from the returnable column as intended. The non-returnable column would read as `NULL`, resulting in wrong query results.

- Ensure that casting to an unspecified typmod generates a `RelabelType` node rather than a length-coercion function call (Tom Lane)

While the coercion function should do the right thing (nothing), this translation is undesirably inefficient.

- Fix checking of `anycompatible`-family data type matches (Tom Lane)

In some cases the parser would think that a function or operator with `anycompatible`-family polymorphic parameters matches a set of arguments that it really shouldn't match. In reported cases, that led to matching more than one operator to a call, leading to ambiguous-operator errors; but a failure later on is also possible.

- Fix WAL replay failure when database consistency is reached exactly at a WAL page boundary (Álvaro Herrera)
- Fix startup of a physical replica to tolerate transaction ID wraparound (Abhijit Menon-Sen, Tomas Vondra)

If a replica server is started while the set of active transactions on the primary crosses a wraparound boundary (so that there are some newer transactions with smaller XIDs than older ones), the replica would fail with "out-of-order XID insertion in KnownAssignedXids". The replica would retry, but could never get past that error.

- In logical replication, avoid double transmission of a child table's data (Hou Zhijie)

If a publication includes both child and parent tables, and has the `publish_via_partition_root` option set, subscribers uselessly initiated synchronization on both child and parent tables. Ensure that only the parent table is synchronized in such cases.

- Remove lexical limitations for SQL commands issued on a logical replication connection (Tom Lane)

The walsender process would fail for a SQL command containing an unquoted semicolon, or with dollar-quoted literals containing odd numbers of single or double quote marks, or when the SQL command starts with a comment. Moreover, faulty error recovery could lead to unexpected errors in later commands too.

- Fix possible loss of the commit timestamp for the last subtransaction of a transaction (Alex Kingsborough, Kyotaro Horiguchi)
- Be sure to `fsync` the `pg_logical/mappings` subdirectory during checkpoints (Nathan Bossart)

On some filesystems this oversight could lead to losing logical rewrite status files after a system crash.

- Build extended statistics for partitioned tables (Justin Pryzby)

A previous bug fix disabled building of extended statistics for old-style inheritance trees, but it also prevented building them for partitioned tables, which was an unnecessary restriction. This change allows `ANALYZE` to compute values for statistics objects for partitioned tables. (But note that `autovacuum` does not process partitioned tables as such, so you must periodically issue manual `ANALYZE` on the partitioned table if you want to maintain such statistics.)

- Ignore extended statistics for inheritance trees (Justin Pryzby)

Currently, extended statistics values are only computed locally for each table, not for entire inheritance trees. However the values were mistakenly consulted when planning queries across inheritance trees, possibly resulting in worse-than-default estimates.

- Disallow altering data type of a partitioned table's columns when the partitioned table's row type is used as a composite type elsewhere (Tom Lane)

This restriction has long existed for regular tables, but through an oversight it was not checked for partitioned tables.

- Disallow `ALTER TABLE ... DROP NOT NULL` for a column that is part of a replica identity index (Haiying Tang, Hou Zhijie)

The same prohibition already existed for primary key indexes.

- Correctly update cached table state during `ALTER TABLE ADD PRIMARY KEY USING INDEX` (Hou Zhijie)

Concurrent sessions failed to update their opinion of whether the table has a primary key, possibly causing incorrect logical replication behavior.

- Correctly update cached table state when switching `REPLICA IDENTITY` index (Tang Haiying, Hou Zhijie)

Concurrent sessions failed to update their opinion of which index is the replica identity one, possibly causing incorrect logical replication behavior.

- Allow parallel vacuuming and concurrent index building to be ignored while computing oldest `xmin` (Masahiko Sawada)

Non-parallelized instances of these operations were already ignored, but the logic did not work for parallelized cases. Holding back the `xmin` horizon has undesirable effects such as delaying vacuum cleanup.

- Avoid leaking memory during `REASSIGN OWNED BY` operations that reassign ownership of many objects (Justin Pryzby)
- Improve performance of walsenders sending logical changes by avoiding unnecessary cache accesses (Hou Zhijie)
- Fix display of `cert` authentication method's options in `pg_hba_file_rules` view (Magnus Hagander)

The `cert` authentication method implies `clientcert=verify-full`, but the `pg_hba_file_rules` view incorrectly reported `clientcert=verify-ca`.

- Fix display of whole-row variables appearing in `INSERT ... VALUES` rules (Tom Lane)

A whole-row variable would be printed as “var.\*”, but that allows it to be expanded to individual columns when the rule is reloaded, resulting in different semantics. Attach an explicit cast to prevent that, as we do elsewhere.

- Fix one-byte buffer overrun when applying Unicode string normalization to an empty string (Michael Paquier)

The practical impact of this is limited thanks to alignment considerations; but in debug builds, a warning was raised.

- Fix or remove some incorrect assertions (Simon Riggs, Michael Paquier, Alexander Lakhin)

These errors should affect only debug builds, not production.

- Fix race condition that could lead to failure to localize error messages that are reported early in multi-threaded use of libpq or ecpglib (Tom Lane)
- Avoid calling `strerror` from libpq's `PQcancel` function (Tom Lane)

`PQcancel` is supposed to be safe to call from a signal handler, but `strerror` is not safe. The faulty usage only occurred in the unlikely event of failure to send the cancel message to the server, perhaps explaining the lack of reports.

- Make `psql`'s `\password` command default to setting the password for `CURRENT_USER`, not the connection's original user name (Tom Lane)

This agrees with the documented behavior, and avoids probable permissions failure if `SET ROLE` or `SET SESSION AUTHORIZATION` has been done since the session began. To prevent confusion, the role name to be acted on is now included in the password prompt.

- Fix `psql \d` command's query for identifying parent triggers (Justin Pryzby)

The previous coding failed with “more than one row returned by a subquery used as an expression” if a partition had triggers and there were unrelated statement-level triggers of the same name on some parent partitioned table.

- Fix `psql`'s tab-completion of label values for enum types (Tom Lane)
- In `psql` and some other client programs, avoid trying to invoke `gettext()` from a control-C signal handler (Tom Lane)

While no reported failures have been traced to this mistake, it seems highly unlikely to be a safe thing to do.

- Allow canceling the initial password prompt in `pg_receivewal` and `pg_recvlogical` (Tom Lane, Nathan Bossart)

Previously it was impossible to terminate these programs via control-C while they were prompting for a password.

- Fix `pg_dump`'s dump ordering for user-defined casts (Tom Lane)

In rare cases, the output script might refer to a user-defined cast before it had been created.

- Fix `pg_dump`'s `--inserts` and `--column-inserts` modes to handle tables containing both generated columns and dropped columns (Tom Lane)
- Fix possible mis-reporting of errors in `pg_dump` and `pg_basebackup` (Tom Lane)

The previous code failed to check for errors from some kernel calls, and could report the wrong `errno` values in other cases.

- Fix results of index-only scans on `contrib/btree_gist` indexes on `char(N)` columns (Tom Lane)

Index-only scans returned column values with trailing spaces removed, which is not the expected behavior. That happened because that's how the data was stored in the index. This fix changes the

code to store `char(N)` values with the expected amount of space padding. The behavior of such an index will not change immediately unless you `REINDEX` it; otherwise space-stripped values will be gradually replaced over time during updates. Queries that do not use index-only scan plans will be unaffected in any case.

- Change `configure` to use Python's `sysconfig` module, rather than the deprecated `distutils` module, to determine how to build PL/Python (Peter Eisentraut, Tom Lane, Andres Freund)

With Python 3.10, this avoids `configure`-time warnings about `distutils` being deprecated and scheduled for removal in Python 3.12. Presumably, once 3.12 is out, `configure --with-python` would fail altogether. This future-proofing does come at a cost: `sysconfig` did not exist before Python 2.7, nor before 3.2 in the Python 3 branch, so it is no longer possible to build PL/Python against long-dead Python versions.

- Fix PL/Perl compile failure on Windows with Perl 5.28 and later (Victor Wagner)
- Fix PL/Python compile failure with Python 3.11 and later (Peter Eisentraut)
- Add support for building with Visual Studio 2022 (Hans Buschmann)
- Allow the `.bat` wrapper scripts in our MSVC build system to be called without first changing into their directory (Anton Voloshin, Andrew Dunstan)

## E.12. Release 13.5

**Release date:** 2021-11-11

This release contains a variety of fixes from 13.4. For information about new features in major release 13, see [Section E.17](#).

### E.12.1. Migration to Version 13.5

A dump/restore is not required for those running 13.X.

However, note that installations using physical replication should update standby servers before the primary server, as explained in the third changelog entry below.

Also, several bugs have been found that may have resulted in corrupted indexes, as explained in the next several changelog entries. If any of those cases apply to you, it's recommended to reindex possibly-affected indexes after updating.

Also, if you are upgrading from a version earlier than 13.2, see [Section E.15](#).

### E.12.2. Changes

- Make the server reject extraneous data after an SSL or GSS encryption handshake (Tom Lane)

A man-in-the-middle with the ability to inject data into the TCP connection could stuff some cleartext data into the start of a supposedly encryption-protected database session. This could be abused to send faked SQL commands to the server, although that would only work if the server did not demand any authentication data. (However, a server relying on SSL certificate authentication might well not do so.)

The PostgreSQL Project thanks Jacob Champion for reporting this problem. (CVE-2021-23214)

- Make `libpq` reject extraneous data after an SSL or GSS encryption handshake (Tom Lane)

A man-in-the-middle with the ability to inject data into the TCP connection could stuff some cleartext data into the start of a supposedly encryption-protected database session. This could probably be abused to inject faked responses to the client's first few queries, although other details of `libpq`'s behavior make that harder than it sounds. A different line of attack is to exfiltrate the client's password, or other sensitive data that might be sent early in the session. That has been shown to be possible with a server vulnerable to CVE-2021-23214.

The PostgreSQL Project thanks Jacob Champion for reporting this problem. (CVE-2021-23222)

- Fix physical replication for cases where the primary crashes after shipping a WAL segment that ends with a partial WAL record (Álvaro Herrera)

If the primary did not survive long enough to finish writing the rest of the incomplete WAL record, then the previous crash-recovery logic had it back up and overwrite WAL starting from the beginning of the incomplete WAL record. This is problematic since standby servers may already have copies of that WAL segment. They will then see an inconsistent next segment, and will not be able to recover without manual intervention. To fix, do not back up over a WAL segment boundary when restarting after a crash. Instead write a new type of WAL record at the start of the next WAL segment, informing readers that the incomplete WAL record will never be finished and must be disregarded.

When applying this update, it's best to update standby servers before the primary, so that they will be ready to handle this new WAL record type if the primary happens to crash.

- Fix `CREATE INDEX CONCURRENTLY` to wait for the latest prepared transactions (Andrey Borodin)

Rows inserted by just-prepared transactions might be omitted from the new index, causing queries relying on the index to miss such rows. The previous fix for this type of problem failed to account for `PREPARE TRANSACTION` commands that were still in progress when `CREATE INDEX CONCURRENTLY` checked for them. As before, in installations that have enabled prepared transactions (`max_prepared_transactions > 0`), it's recommended to reindex any concurrently-built indexes in case this problem occurred when they were built.

- Avoid race condition that can cause backends to fail to add entries for new rows to an index being built concurrently (Noah Misch, Andrey Borodin)

While it's apparently rare in the field, this case could potentially affect any index built or reindexed with the `CONCURRENTLY` option. It is recommended to reindex any such indexes to make sure they are correct.

- Fix `float4` and `float8` hash functions to produce uniform results for NaNs (Tom Lane)

Since PostgreSQL's floating-point types deem all NaNs to be equal, it's important for the hash functions to produce the same hash code for all bit-patterns that are NaNs according to the IEEE 754 standard. This failed to happen before, meaning that hash indexes and hash-based query plans might produce incorrect results for non-canonical NaN values. (`'-NaN'::float8` is one way to produce such a value on most machines.) It is advisable to reindex hash indexes on floating-point columns, if there is any possibility that they might contain such values.

- Fix `REINDEX CONCURRENTLY` to preserve operator class parameters that were attached to the target index (Michael Paquier)
- Prevent data loss during crash recovery of `CREATE TABLESPACE`, when `wal_level = minimal` (Noah Misch)

If the server crashed between `CREATE TABLESPACE` and the next checkpoint, replay would fully remove the contents of the new tablespace's directory, relying on subsequent WAL replay to restore everything within that directory. This interacts badly with optimizations that skip writing WAL (one example is `COPY` into a just-created table). Such optimizations are applied only when `wal_level` is `minimal`, which is not the default in v10 and later.

- Ensure that the relation cache is invalidated for a table being attached to or detached from a partitioned table (Amit Langote, Álvaro Herrera)

This oversight could allow misbehavior of subsequent inserts/updates addressed directly to the partition, but only in currently-existing sessions.

- Ensure that the relation cache is invalidated for all partitions of a partitioned table that is being added to or removed from a publication (Hou Zhijie, Vignesh C)

This oversight could lead to improper replication behavior until all currently-existing sessions have exited.

- Ensure that the relation cache is invalidated when creating or dropping a `FOR ALL TABLES` publication (Hou Zhijie, Vignesh C)

This oversight could lead to improper replication behavior until all currently-existing sessions have exited.

- Don't discard a cast to the same type with unspecified type modifier (Tom Lane)

For example, if column `f1` is of type `numeric(18,3)`, the parser used to simply discard a cast like `f1::numeric`, on the grounds that it would have no run-time effect. That's true, but the exposed type of the expression should still be considered to be plain `numeric`, not `numeric(18,3)`. This is important for correctly resolving the type of larger constructs, such as recursive `UNIONS`.

- Fix updates of element fields in arrays of domain over composite (Tom Lane)

A command such as `UPDATE tab SET fld[1].subfld = val` failed if the array's elements were domains rather than plain composites.

- Disallow the combination of `FETCH FIRST WITH TIES` and `FOR UPDATE SKIP LOCKED` (David Christensen)

`FETCH FIRST WITH TIES` necessarily fetches one more row than requested, since it cannot stop until it finds a row that is not a tie. In our current implementation, if `FOR UPDATE` is used then that row will also get locked even though it is not returned. That results in undesirable behavior if the `SKIP LOCKED` option is specified. It's difficult to change this without introducing a different set of undesirable behaviors, so for now, forbid the combination.

- Disallow creating an ICU collation if the current database's encoding won't support it (Tom Lane)

Previously this was allowed, but then the collation could not be referenced because of the way collation lookup works; you could not use the collation, nor even drop it.

- Disallow `ALTER INDEX index ALTER COLUMN col SET (options)` (Nathan Bossart, Michael Paquier)

While the parser accepted this, it's undocumented and doesn't actually work.

- Fix corner-case loss of precision in `numeric power()` (Dean Rasheed)

The result could be inaccurate when the first argument is very close to 1.

- Avoid regular expression errors with capturing parentheses inside `{0}` (Tom Lane)

Regular expressions like `(.){0}...\1` drew "invalid backreference number". Other regexp engines such as Perl don't complain, though, and for that matter ours doesn't either in some closely related cases. Worse, it could throw an assertion failure instead. Fix it so that no error is thrown and instead the back-reference is silently deemed to never match.

- Prevent regular expression back-references from sometimes matching when they shouldn't (Tom Lane)

The regexp engine was careless about clearing match data for capturing parentheses after rejecting a partial match. This could allow a later back-reference to match in places where it should fail for lack of a defined referent.

- Fix regular expression performance bug with back-references inside iteration nodes (Tom Lane)

Incorrect back-tracking logic could result in exponential time spent looking for a match. Fortunately the problem is masked in most cases by other optimizations.

- Fix incorrect results from `AT TIME ZONE` applied to a time with time zone value (Tom Lane)

The results were incorrect if the target time zone was specified by a dynamic timezone abbreviation (that is, one that is defined as equivalent to a full time zone name, rather than a fixed UTC offset).

- Fix planner error with pulling up subquery expressions into function rangetable entries (Tom Lane)  
If a function in `FROM` laterally references the output of some sub-`SELECT` earlier in the `FROM` clause, and we are able to flatten that sub-`SELECT` into the outer query, the expression(s) copied into the function expression were not fully processed. This could lead to crashes at execution.
- Fix mistranslation of PlaceholderVars to inheritance child relations (Tom Lane)  
This error could result in assertion failures, or in mis-planning of queries having partitioned or inherited tables on the nullable side of an outer join.
- Avoid using MCV-only statistics to estimate the range of a column (Tom Lane)  
There are corner cases in which `ANALYZE` will build a most-common-values (MCV) list but not a histogram, even though the MCV list does not account for all the observed values. In such cases, keep the planner from using the MCV list alone to estimate the range of column values.
- Fix restoration of a Portal's snapshot inside a subtransaction (Bertrand Drouvot)  
If a procedure commits or rolls back a transaction, and then its next significant action is inside a new subtransaction, snapshot management went wrong, leading to a dangling pointer and probable crash. A typical example in PL/pgSQL is a `COMMIT` immediately followed by a `BEGIN ... EXCEPTION` block that performs a query.
- Clean up correctly if a transaction fails after exporting its snapshot (Dilip Kumar)  
This oversight would only cause a problem if the same session attempted to export a snapshot again. The most likely scenario for that is creation of a replication slot (followed by rollback) and then creation of another replication slot.
- Prevent wraparound of overflowed-subtransaction tracking on standby servers (Kyotaro Horiguchi, Alexander Korotkov)  
This oversight could cause significant performance degradation (manifesting as excessive SubtransSLRU traffic) on standby servers.
- Ensure that prepared transactions are properly accounted for during promotion of a standby server (Michael Paquier, Andres Freund)  
There was a narrow window where a prepared transaction could be omitted from a snapshot taken by a concurrently-running session. If that session then used the snapshot to perform data updates, erroneous results or data corruption could occur.
- Disallow `LISTEN` in background workers (Tom Lane)  
There's no infrastructure to support this, so if someone did it, it would only result in preventing cleanup of the `NOTIFY` queue.
- Send `NOTIFY` signals to other backends during transaction commit, not in the server's idle loop (Artur Zakirov, Tom Lane)  
This change allows notifications to be delivered immediately after an intra-procedure `COMMIT`. It also allows logical replication workers to send notifications.
- Refuse to rewind a cursor marked `NO SCROLL` if it has been held over from a previous transaction due to the `WITH HOLD` option (Tom Lane)  
We have long forbidden fetching backwards from a `NO SCROLL` cursor, but for historical reasons the prohibition didn't extend to cases in which we rewind the query altogether and then re-fetch forwards. That exception leads to inconsistencies, particularly for held-over cursors which may not have stored all the data necessary to rewind. Disallow rewinding for non-scrollable held-over cursors to block the worst inconsistencies. (v15 will remove the exception altogether.)
- Fix possible failure while saving a `WITH HOLD` cursor at transaction end, if it had already been read to completion (Tom Lane)

- Fix detection of a relation that has grown to the maximum allowed length (Tom Lane)

An attempt to extend a table or index past the limit of  $2^{32}-1$  blocks was rejected, but not soon enough to prevent inconsistent internal state from being created.

- Correctly track the presence of data-modifying CTEs when expanding a `DO INSTEAD` rule (Greg Nancarrow, Tom Lane)

The previous failure to do this could lead to problems such as unsafely choosing a parallel plan.

- Fix incorrect reporting of permissions failures on extended statistics objects (Tomas Vondra)

The code typically produced “cache lookup error” rather than the intended message.

- Fix incorrect snapshot handling in parallel workers (Greg Nancarrow)

This oversight could lead to misbehavior in parallel queries if the transaction isolation level is less than `REPEATABLE READ`.

- Fix logical decoding to correctly ignore toast-table changes for transient tables (Bertrand Drouvot)

Logical decoding normally ignores changes in transient tables such as those created during an `ALTER TABLE` heap rewrite. But that filtering wasn't applied to the associated toast table if any, leading to possible errors when rewriting a table that's being published.

- Fix logical decoding's memory usage accounting to handle TOAST data correctly (Bertrand Drouvot)
- Ensure that walreceiver processes create all required archive notification files before exiting (Fujii Masao)

If a walreceiver exited exactly at a WAL segment boundary, it failed to make a notification file for the last-received segment, thus delaying archiving of that segment on the standby.

- Fix computation of the WAL range to include in a backup manifest when a timeline change is involved (Kyotaro Horiguchi)
- Avoid trying to lock the `OLD` and `NEW` pseudo-relations in a rule that uses `SELECT FOR UPDATE` (Masahiko Sawada, Tom Lane)
- Fix parser's processing of aggregate `FILTER` clauses (Tom Lane)

If the `FILTER` expression is a plain boolean column, the semantic level of the aggregate could be mis-determined, leading to not-per-spec behavior. If the `FILTER` expression is itself a boolean-returning aggregate, an error should be thrown but was not, likely resulting in a crash at execution.

- Ensure that the correct lock level is used when renaming a table (Nathan Bossart, Álvaro Herrera)

For historical reasons, `ALTER INDEX ... RENAME` can be applied to any sort of relation. The lock level required to rename an index is lower than that required to rename a table or other kind of relation, but the code got this wrong and would use the weaker lock level whenever the command is spelled `ALTER INDEX`.

- Prevent `ALTER TYPE/DOMAIN/OPERATOR ... SET` from changing extension membership (Tom Lane)

`ALTER ... SET` executed by an extension script would cause the target object to become a member of the extension if it was not already. In itself this isn't too troubling, since there's little reason for an extension script to touch an object not belonging to the extension. But `ALTER TYPE SET` will recurse to dependent domains, thus causing them to also become extension members. This causes unwanted side-effects from extension upgrade scripts that use that command to adjust the properties of a base type belonging to the extension. Fix by redefining these `ALTER` cases to never change extension membership.

- Avoid trying to clean up LLVM state after an error within LLVM (Andres Freund, Justin Pryzby)

This prevents a likely crash during backend exit after a fatal LLVM error.

- Avoid null-pointer-dereference crash when dropping a role that owns objects being dropped concurrently (Álvaro Herrera)
- Prevent “snapshot reference leak” warning when `lo_export()` or a related function fails (Heikki Linnakangas)
- Ensure that scans of SP-GiST indexes are counted in the statistics views (Tom Lane)

Incrementing the number-of-index-scans counter was overlooked in the SP-GiST code, although per-tuple counters were advanced correctly.

- Fix inefficient code generation for `CoerceToDomain` expression nodes (Ranier Vilela)
- Recalculate relevant wait intervals if `recovery_min_apply_delay` is changed during recovery (Soumyadeep Chakraborty, Ashwin Agrawal)
- Fix infinite loop if a `simplehash.h` hash table reaches  $2^{32}$  elements (Yura Sokolov)

It seems unlikely that this bug has been hit in practice, as it would require `work_mem` settings of hundreds of gigabytes for existing uses of `simplehash.h`.

- Avoid  $O(N^2)$  behavior in some list-manipulation operations (Nathan Bossart, Tom Lane)

These changes fix slow processing in several scenarios, including: when a standby replays a transaction that held many exclusive locks on the primary; when many files are due to be unlinked after a checkpoint; when hash aggregation involves many batches; and when `pg_trgm` extracts indexable conditions from a complex regular expression. Only the first of these scenarios has actually been reported from the field, but they all seem like plausible consequences of inefficient list deletions.

- Reduce memory consumption during calculation of extended statistics (Justin Pryzby, Tomas Vondra)
- Add more defensive checks around B-tree posting list splits (Peter Geoghegan)

This change should help detect index corruption involving duplicate table TIDs.

- Disallow setting `huge_pages` to `on` when `shared_memory_type` is `sysv` (Thomas Munro)

Previously, this setting was accepted, but it did nothing for lack of any implementation.

- Fix missing `libpq` functions on AIX (Tony Reix)

Code reorganization led to the following documented functions not being exported from `libpq` on AIX: `pg_encoding_to_char()`, `pg_utf_mblen()`, `pg_char_to_encoding()`, `pg_valid_server_encoding()`, and `pg_valid_server_encoding_id()`. Restore them to visibility.

- Fix `ecpg` to recover correctly after `malloc()` failure while establishing a connection (Michael Paquier)
- Fix miscalculation of stable functions called in the arguments of a PL/pgSQL `CALL` statement (Tom Lane)

They were being called with an out-of-date snapshot, so that they would not see any database changes made since the start of the session's top-level command.

- Allow `EXIT` out of the outermost block in a PL/pgSQL routine (Tom Lane)

If the routine does not require an explicit `RETURN`, this usage should be valid, but it was rejected.

- Remove `pg_ctl`'s hard-coded limits on the total length of generated commands (Phil Krylov)

For example, this removes a restriction on how many command-line options can be passed through to the postmaster. Individual path names that `pg_ctl` deals with, such as the postmaster executable's name or the data directory name, are still limited to `MAXPGPATH` bytes in most cases.

- Fix `pg_dump` to dump non-global default privileges correctly (Neil Chen, Masahiko Sawada)

If a global (unrestricted) `ALTER DEFAULT PRIVILEGES` command revoked some present-by-default privilege, for example `EXECUTE` for functions, and then a restricted `ALTER DEFAULT PRIVILEGES` command granted that privilege again for a selected role or schema, `pg_dump` failed to dump the restricted privilege grant correctly.

- Make `pg_dump` acquire shared lock on partitioned tables that are to be dumped (Tom Lane)

This oversight was usually pretty harmless, since once `pg_dump` has locked any of the leaf partitions, that would suffice to prevent significant DDL on the partitioned table itself. However problems could ensue when dumping a childless partitioned table, since no relevant lock would be held.

- Improve `pg_dump`'s performance by avoiding making per-table queries for RLS policies, and by avoiding repetitive calls to `format_type()` (Tom Lane)

These changes provide only marginal improvement when dumping from a local server, but a dump from a remote server can benefit substantially due to fewer network round-trips.

- Fix crash in `pg_dump` when attempting to dump trigger definitions from a pre-8.3 server (Tom Lane)
- Fix incorrect filename in `pg_restore`'s error message about an invalid large object TOC file (Daniel Gustafsson)
- Ensure that `pgbench` exits with non-zero status after a socket-level failure (Yugo Nagata, Fabien Coelho)

The desired behavior is to finish out the run but then exit with status 2. Also, fix the reporting of such errors.

- Fix failure of `contrib/btree_gin` indexes on "char" (not `char(n)`) columns, when an indexscan using the `<` or `<=` operator is performed (Tom Lane)

Such an indexscan failed to return all the entries it should.

- Change `contrib/pg_stat_statements` to read its "query texts" file in units of at most 1GB (Tom Lane)

Such large query text files are very unusual, but if they do occur, the previous coding would fail on Windows 64 (which rejects individual read requests of more than 2GB).

- Fix null-pointer crash when `contrib/postgres_fdw` tries to report a data conversion error (Tom Lane)
- Add spinlock support for the RISC-V architecture (Marek Szuba)

This is essential for reasonable performance on that platform.

- Support OpenSSL 3.0.0 (Peter Eisentraut, Daniel Gustafsson, Michael Paquier)
- Set correct type identifier on OpenSSL BIO (I/O abstraction) objects created by PostgreSQL (Itamar Gafni)

This oversight probably only matters for code that is doing tasks like auditing the OpenSSL installation. But it's nominally a violation of the OpenSSL API, so fix it.

- Fix our `pkg-config` files to again support static linking of `libpq` (Peter Eisentraut)
- Make `pg_regexec()` robust against an out-of-range `search_start` parameter (Tom Lane)

Return `REG_NOMATCH`, instead of possibly crashing, when `search_start` is past the end of the string. This case is probably unreachable within core PostgreSQL, but extensions might be more careless about the parameter value.

- Ensure that `GetSharedSecurityLabel()` can be used in a newly-started session that has not yet built its critical relation cache entries (Jeff Davis)
- Use the CLDR project's data to map Windows time zone names to IANA time zones (Tom Lane)

When running on Windows, `initdb` attempts to set the new cluster's `timezone` parameter to the IANA time zone matching the system's prevailing time zone. We were using a mapping table that we'd generated years ago and updated only fitfully; unsurprisingly, it contained a number of errors as well as omissions of recently-added zones. It turns out that CLDR has been tracking the most appropriate mappings, so start using their data. This change will not affect any existing installation, only newly-initialized clusters.

- Update time zone data files to `tzdata` release 2021e for DST law changes in Fiji, Jordan, Palestine, and Samoa, plus historical corrections for Barbados, Cook Islands, Guyana, Niue, Portugal, and Tonga.

Also, the Pacific/Enderbury zone has been renamed to Pacific/Kanton. Also, the following zones have been merged into nearby, more-populous zones whose clocks have agreed with them since 1970: Africa/Accra, America/Atikokan, America/Blanc-Sablon, America/Creston, America/Curacao, America/Nassau, America/Port\_of\_Spain, Antarctica/DumontDURville, and Antarctica/Syowa. In all these cases, the previous zone name remains as an alias.

## E.13. Release 13.4

**Release date:** 2021-08-12

This release contains a variety of fixes from 13.3. For information about new features in major release 13, see [Section E.17](#).

### E.13.1. Migration to Version 13.4

A dump/restore is not required for those running 13.X.

However, if you are upgrading from a version earlier than 13.2, see [Section E.15](#).

### E.13.2. Changes

- Fix mis-planning of repeated application of a projection step (Tom Lane)

The planner could create an incorrect plan in cases where two `ProjectionPaths` were stacked on top of each other. The only known way to trigger that situation involves parallel sort operations, but there may be other instances. The result would be crashes or incorrect query results. Disclosure of server memory contents is also possible. (CVE-2021-3677)

- Disallow SSL renegotiation more completely (Michael Paquier)

SSL renegotiation has been disabled for some time, but the server would still cooperate with a client-initiated renegotiation request. A maliciously crafted renegotiation request could result in a server crash (see OpenSSL issue CVE-2021-3449). Disable the feature altogether on OpenSSL versions that permit doing so, which are 1.1.0h and newer.

- Restore the Portal-level snapshot after `COMMIT` or `ROLLBACK` within a procedure (Tom Lane)

This change fixes cases where an attempt to fetch a toasted value immediately after `COMMIT/ROLLBACK` would fail with errors like “no known snapshots” or “missing chunk number 0 for toast value”.

Some extensions may attempt to execute SQL code outside of any Portal. They are responsible for ensuring that an outer snapshot exists before doing so. Previously, not providing a snapshot might work or it might not; now it will consistently fail with “cannot execute SQL without an outer snapshot or portal”.

- Avoid misbehavior when persisting the output of a cursor that's reading a non-stable query (Tom Lane)

Previously, we'd always rewind and re-read the whole query result, possibly getting results different from the earlier execution, causing great confusion later. For a NO SCROLL cursor, we can fix this by only storing the not-yet-read portion of the query output, which is sufficient since a NO SCROLL cursor can't be backed up. Cursors with the SCROLL option remain at hazard, but that was already documented to be an unsafe option to use with a non-stable query. Make those documentation warnings stronger.

Also force NO SCROLL mode for the implicit cursor used by a PL/pgSQL FOR-over-query loop, to avoid this type of problem when persisting such a cursor during an intra-procedure commit.

- Reject `SELECT ... GROUP BY GROUPING SETS (( )) FOR UPDATE` (Tom Lane)

This should be disallowed, just as `FOR UPDATE` with a plain `GROUP BY` is disallowed, but the test for that failed to handle empty grouping sets correctly. The end result would be a null-pointer dereference in the executor.

- Reject cases where a query in `WITH` rewrites to just `NOTIFY` (Tom Lane)

Such cases previously crashed.

- In `numeric` multiplication, round the result rather than failing if it would have more than 16383 digits after the decimal point (Dean Rasheed)
- Fix corner-case errors and loss of precision when raising `numeric` values to very large powers (Dean Rasheed)
- Fix division-by-zero failure in `to_char()` with `EEEE` format and a `numeric` input value less than  $10^{(-1001)}$  (Dean Rasheed)
- Fix `pg_size_pretty(bigint)` to round negative values consistently with the way it rounds positive ones (and consistently with the `numeric` version) (Dean Rasheed, David Rowley)
- Make `pg_filenode_relation(0, 0)` return NULL rather than failing (Justin Pryzby)
- Make `ALTER EXTENSION` lock the extension when adding or removing a member object (Tom Lane)

The previous coding allowed `ALTER EXTENSION ADD/DROP` to occur concurrently with `DROP EXTENSION`, leading to a crash or corrupt catalog entries.

- Fix `ALTER SUBSCRIPTION` to reject an empty slot name (Japin Li)
- When cloning a partitioned table's triggers to a new partition, ensure that their enabled status is copied (Álvaro Herrera)
- Avoid alias conflicts in queries generated for `REFRESH MATERIALIZED VIEW CONCURRENTLY` (Tom Lane, Bharath Rupireddy)

This command failed on materialized views containing columns with certain names, notably `mv` and `newdata`.

- Fix `PREPARE TRANSACTION` to check correctly for conflicting session-lifespan and transaction-lifespan locks (Tom Lane)

A transaction cannot be prepared if it has both session-lifespan and transaction-lifespan locks on the same advisory-lock ID value. This restriction was not fully checked, which could lead to a PANIC during `PREPARE TRANSACTION`.

- Fix misbehavior of `DROP OWNED BY` when the target role is listed more than once in an RLS policy (Tom Lane)
- Skip unnecessary error tests when removing a role from an RLS policy during `DROP OWNED BY` (Tom Lane)

Notably, this fixes some cases where it was necessary to be a superuser to use `DROP OWNED BY`.

- Re-allow old-style Windows locale names in `CREATE COLLATION` commands (Thomas Munro)

Previously we were failing because the operating system can't provide version information for such locales. At some point we may decide to require version information, but no such policy exists yet, so re-allow the case for now.

- Disallow whole-row variables in `GENERATED` expressions (Tom Lane)

Use of a whole-row variable clearly violates the rule that a generated column cannot depend on itself, so such cases have no well-defined behavior. The actual behavior frequently included a crash.

- Fix usage of `tableoid` in `GENERATED` expressions (Tom Lane)

Some code paths failed to provide a valid value for this system column while evaluating a `GENERATED` expression.

- Don't store a "fast default" when adding a column to a foreign table (Andrew Dunstan)

The fast default is useless since no local heap storage exists for such a table, but it confused subsequent operations. In addition to suppressing creation of such catalog entries in `ALTER TABLE` commands, adjust the downstream code to cope when one is incorrectly present.

- Allow index state flags to be updated transactionally (Michael Paquier, Andrey Lepikhov)

This avoids failures when dealing with index predicates that aren't really immutable. While that's not considered a supported case, the original reason for using a non-transactional update here is long gone, so we may as well change it.

- Avoid corrupting the plan cache entry when `CREATE DOMAIN` or `ALTER DOMAIN` appears in a cached plan (Tom Lane)
- Make walsenders show their latest replication commands in `pg_stat_activity` (Tom Lane)

Previously, a walsender would show its latest SQL command, which was confusing if it's now doing some replication operation instead. Now we show replication-protocol commands on the same footing as SQL commands.

- Make `pg_settings.pending_restart` show as true when the pertinent entry in `postgresql.conf` has been removed (Álvaro Herrera)

`pending_restart` correctly showed the case where an entry that cannot be changed without a postmaster restart has been modified, but not where the entry had been removed altogether.

- On 64-bit Windows, allow the effective value of `work_mem` times `hash_mem_multiplier` to exceed 2GB (Tom Lane)

This allows `hash_mem_multiplier` to be used for its intended purpose of preventing large hash aggregations from spilling to disk, even when "large" means multiple gigabytes.

- Fix mis-planning of queries involving regular tables that are inheritance children of foreign tables (Amit Langote)

`SELECT FOR UPDATE` and related commands would fail with assertion failures or "could not find junk column" errors in such cases.

- Fix pullup of constant function-in-FROM results when the FROM item is marked `LATERAL` (Tom Lane)

- Fix corner-case failure of a new standby to follow a new primary (Dilip Kumar, Robert Haas)

Under a narrow combination of conditions, the standby could wind up trying to follow the wrong WAL timeline.

- Update minimum recovery point when WAL replay of a transaction abort record causes file truncation (Fujii Masao)

File truncation is irreversible, so it's no longer safe to stop recovery at a point earlier than that record. The corresponding case for transaction commit was fixed years ago, but this one was overlooked.

- Advance oldest-required-WAL-segment horizon properly after a replication slot is invalidated (Kyotaro Horiguchi)

If all slots were invalidated, the horizon would not move again, eventually allowing the server's WAL storage to run out of space.

- In walreceivers, avoid attempting catalog lookups after an error (Masahiko Sawada, Bharath Rupireddy)
- Ensure that a standby server's startup process will respond to a shutdown signal promptly while waiting for WAL to arrive (Fujii Masao, Soumyadeep Chakraborty)
- Correctly clear shared state after failing to become a member of a transaction commit group (Amit Kapila)

Given the right timing, this could cause an assertion failure when some later session re-uses the same PGPROC object.

- Add locking to avoid reading incorrect relmapper data in the face of a concurrent write from another process (Heikki Linnakangas)
- Improve progress reporting for the sort phase of a parallel btree index build (Matthias van de Meent)
- Improve checks for violations of replication protocol (Tom Lane)

Logical replication workers frequently used Asserts to check for cases that could be triggered by invalid or out-of-order replication commands. This seems unwise, so promote these tests to regular error checks.

- Fix assorted crash cases in logical replication of partitioned-table updates (Amit Langote, Tom Lane)
- Fix potential crash when firing AFTER triggers of partitioned tables in logical replication workers (Tom Lane)
- Fix deadlock when multiple logical replication workers try to truncate the same table (Peter Smith, Haiying Tang)
- Fix error cases and memory leaks in logical decoding of speculative insertions (Dilip Kumar)
- Fix memory leak in logical replication output (Amit Langote)
- Avoid leaving an invalid record-type hash table entry behind after an error (Sait Talha Nisanci)

This could lead to later crashes or memory leakage.

- Fix plan cache reference leaks in some error cases in CREATE TABLE ... AS EXECUTE (Tom Lane)
- Fix race condition in code for sharing tuple descriptors across parallel workers (Thomas Munro)

Given the right timing, a crash could result.

- Fix race condition when invalidating an obsolete replication slot concurrently with an attempt to drop or update it (Andres Freund, Alvaro Herrera)
- Fix possible race condition when releasing BackgroundWorkerSlots (Tom Lane)

It's likely that this doesn't fix any observable bug on Intel hardware, but machines with weaker memory ordering rules could have problems.

- Fix latent crash in sorting code (Ronan Dunklau)

One code path could attempt to free a null pointer. The case appears unreachable in the core server's use of sorting, but perhaps it could be triggered by extensions.

- Harden B-tree posting list split code against corrupt data (Peter Geoghegan)

Throw an error, rather than crashing, for an attempt to insert an item with a TID identical to an existing entry. While that shouldn't ever happen, it has been reported to happen when the index is inconsistent with its table.

- Prevent infinite loops in SP-GiST index insertion (Tom Lane)

In the event that INCLUDE columns take up enough space to prevent a leaf index tuple from ever fitting on a page, the text\_ops operator class would get into an infinite loop vainly trying to make the tuple fit. While pre-v11 versions don't have INCLUDE columns, back-patch this anti-looping fix to them anyway, as it seems like a good defense against bugs in operator classes.

- Ensure that SP-GiST index insertion can be terminated by a query cancel request (Tom Lane, Álvaro Herrera)
- Fix uninitialized-variable bug that could cause PL/pgSQL to act as though an INTO clause specified STRICT, even though it didn't (Tom Lane)
- Don't abort the process for an out-of-memory failure in libpq's printing functions (Tom Lane)
- In ecpg, allow the numeric value INT\_MIN (usually -2147483648) to be converted to integer (John Naylor)
- In psql and other client programs, avoid overrunning the ends of strings when dealing with invalidly-encoded data (Tom Lane)

An incorrectly-encoded multibyte character near the end of a string could cause various processing loops to run past the string's terminating NUL, with results ranging from no detectable issue to a program crash, depending on what happens to be in the following memory. This is reminiscent of CVE-2006-2313, although these particular cases do not appear to have interesting security consequences.

- Fix pg\_dump to correctly handle triggers on partitioned tables whose enabled status is different from their parent triggers' status (Justin Pryzby, Álvaro Herrera)
- Avoid "invalid creation date in header" warnings observed when running pg\_restore on an archive file created in a different time zone (Tom Lane)
- Make pg\_upgrade carry forward the old installation's oldestXID value (Bertrand Drouvot)

Previously, the new installation's oldestXID was set to a value old enough to (usually) force immediate anti-wraparound autovacuuming. That's not desirable from a performance standpoint; what's worse, installations using large values of autovacuum\_freeze\_max\_age could suffer unwanted forced shutdowns soon after an upgrade.

- Extend pg\_upgrade to detect and warn about extensions that should be upgraded (Bruce Momjian)

A script file is now produced containing the ALTER EXTENSION UPDATE commands needed to bring extensions up to the versions that are considered default in the new installation.

- Avoid problems when switching pg\_receivewal between compressed and non-compressed WAL storage (Michael Paquier)
- Fix contrib/postgres\_fdw to work usefully with generated columns (Etsuro Fujita)

postgres\_fdw will now behave reasonably with generated columns, so long as a generated column in a foreign table represents a generated column in the remote table. IMPORT FOREIGN SCHEMA will now import generated columns that way by default.

- In contrib/postgres\_fdw, avoid attempting catalog lookups after an error (Tom Lane)

While this usually worked, it's not very safe since the error might have been one that made catalog access nonfunctional. A side effect of the fix is that messages about data conversion errors will now mention the query's table and column aliases (if used) rather than the true underlying name of a foreign table or column.

- Improve the isolation-test infrastructure (Tom Lane, Michael Paquier)

Allow isolation test steps to be annotated to show the expected completion order. This allows getting stable results from otherwise-racy test cases, without the long delays that we previously used (not entirely successfully) to fend off race conditions. Allow non-quoted identifiers as isolation test session/step names (formerly, all such names had to be double-quoted). Detect and warn about unused steps in isolation tests. Improve display of query results in isolation tests. Remove isolationtester's "dry-run" mode. Remove memory leaks in isolationtester itself.

- Reduce overhead of cache-clobber testing (Tom Lane)
- Fix PL/Python's regression tests to pass with Python 3.10 (Honza Horak)
- Make `printf("%s", NULL)` `print (null)` instead of crashing (Tom Lane)

This should improve server robustness in corner cases, and it syncs our `printf` implementation with common libraries.

- Fix incorrect log message when point-in-time recovery stops at a `ROLLBACK PREPARED` record (Simon Riggs)
- Improve `ALTER TABLE`'s messages for wrong-relation-kind errors (Kyotaro Horiguchi)
- Clarify error messages referring to "non-negative" values (Bharath Rupireddy)
- Fix configure to work with OpenLDAP 2.5, which no longer has a separate `libldap_r` library (Adrian Ho, Tom Lane)

If there is no `libldap_r` library, we now silently assume that `libldap` is thread-safe.

- Add new make targets `world-bin` and `install-world-bin` (Andrew Dunstan)

These are the same as `world` and `install-world` respectively, except that they do not build or install the documentation.

- Fix make rule for TAP tests (`prove_installcheck`) to work in PGXS usage (Andrew Dunstan)
- Adjust JIT code to prepare for forthcoming LLVM API change (Thomas Munro, Andres Freund)

LLVM 13 has made an incompatible API change that will cause crashing of our previous JIT compiler.

- Avoid assuming that strings returned by GSSAPI libraries are null-terminated (Tom Lane)

The GSSAPI spec provides for a string pointer and length. It seems that in practice the next byte after the string is usually zero, so that our previous coding didn't actually fail; but we do have a report of AddressSanitizer complaints.

- Enable building with GSSAPI on MSVC (Michael Paquier)

Fix various incompatibilities with modern Kerberos builds.

- In MSVC builds, include `--with-pgport` in the set of configure options reported by `pg_config`, if it had been specified (Andrew Dunstan)

## E.14. Release 13.3

**Release date:** 2021-05-13

This release contains a variety of fixes from 13.2. For information about new features in major release 13, see [Section E.17](#).

### E.14.1. Migration to Version 13.3

A dump/restore is not required for those running 13.X.

However, if you are upgrading from a version earlier than 13.2, see [Section E.15](#).

## E.14.2. Changes

- Prevent integer overflows in array subscripting calculations (Tom Lane)

The array code previously did not complain about cases where an array's lower bound plus length overflows an integer. This resulted in later entries in the array becoming inaccessible (since their subscripts could not be written as integers), but more importantly it confused subsequent assignment operations. This could lead to memory overwrites, with ensuing crashes or unwanted data modifications. (CVE-2021-32027)

- Fix mishandling of “junk” columns in `INSERT ... ON CONFLICT ... UPDATE` target lists (Tom Lane)

If the `UPDATE` list contains any multi-column sub-selects (which give rise to junk columns in addition to the results proper), the `UPDATE` path would end up storing tuples that include the values of the extra junk columns. That's fairly harmless in the short run, but if new columns are added to the table then the values would become accessible, possibly leading to malfunctions if they don't match the datatypes of the added columns.

In addition, in versions supporting cross-partition updates, a cross-partition update triggered by such a case had the reverse problem: the junk columns were removed from the target list, typically causing an immediate crash due to malfunction of the multi-column sub-select mechanism. (CVE-2021-32028)

- Fix possibly-incorrect computation of `UPDATE ... RETURNING` outputs for joined cross-partition updates (Amit Langote, Etsuro Fujita)

If an `UPDATE` for a partitioned table caused a row to be moved to another partition with a physically different row type (for example, one with a different set of dropped columns), computation of `RETURNING` results for that row could produce errors or wrong answers. No error is observed unless the `UPDATE` involves other tables being joined to the target table. (CVE-2021-32029)

- Fix adjustment of constraint deferrability properties in partitioned tables (Álvaro Herrera)

When applied to a foreign-key constraint of a partitioned table, `ALTER TABLE ... ALTER CONSTRAINT` failed to adjust the `DEFERRABLE` and/or `INITIALLY DEFERRED` markings of the constraints and triggers of leaf partitions. This led to unexpected behavior of such constraints. After updating to this version, any misbehaving partitioned tables can be fixed by executing a new `ALTER` command to set the desired properties.

This change also disallows applying such an `ALTER` directly to the constraints of leaf partitions. The only supported case is for the whole partitioning hierarchy to have identical constraint properties, so such `ALTERS` must be applied at the partition root.

- When attaching a child table with `ALTER TABLE ... INHERIT`, insist that any generated columns in the parent be generated the same way in the child (Peter Eisentraut)
- Forbid marking an identity column as nullable (Vik Fearing)

`GENERATED ... AS IDENTITY` implies `NOT NULL`, so don't allow it to be combined with an explicit `NULL` specification.

- Allow `ALTER ROLE/DATABASE ... SET` to set the `role`, `session_authorization`, and `temp_buffers` parameters (Tom Lane)

Previously, over-eager validity checks might reject these commands, even if the values would have worked when used later. This created a command ordering hazard for dump/reload and upgrade scenarios.

- Ensure that `REINDEX CONCURRENTLY` preserves any statistics target that's been set for the index (Michael Paquier)
- Fix `COMMIT AND CHAIN` to work correctly when the current transaction has live savepoints (Fujii Masao)

- Fix list-manipulation bug in `WITH RECURSIVE` processing (Michael Paquier, Tom Lane)

Sufficiently deep nesting of `WITH` constructs (at least seven levels) triggered core dumps or incorrect complaints of faulty `WITH` nesting.

- Fix bug with coercing the result of a `COLLATE` expression to a non-collatable type (Tom Lane)

This led to a parse tree in which the `COLLATE` appears to be applied to a non-collatable value. While that normally has no real impact (since `COLLATE` has no effect at runtime), it was possible to construct views that would be rejected during dump/reload.

- Fix use-after-free bug in saving tuples for `AFTER` triggers (Amit Langote)

This could cause crashes in some situations.

- Disallow calling window functions and procedures via the “fast path” wire protocol message (Tom Lane)

Only plain functions are supported here. While trying to call an aggregate function failed already, calling a window function would crash, and calling a procedure would work only if the procedure did no transaction control.

- Extend `pg_identify_object_as_address()` to support event triggers (Joel Jacobson)
- Fix `to_char()`'s handling of Roman-numeral month format codes with negative intervals (Julien Rouhaud)

Previously, such cases would usually cause a crash.

- Check that the argument of `pg_import_system_collations()` is a valid schema OID (Tom Lane)
- Fix use of uninitialized value while parsing an `\{m,n\}` quantifier in a BRE-mode regular expression (Tom Lane)

This error could cause the quantifier to act non-greedy, that is behave like an `\{m,n\}?` quantifier would do in full regular expressions.

- Fix “could not find pathkey item to sort” planner errors in some situations where the sort key involves an aggregate or window function (James Coleman, Tom Lane)
- Don't ignore system columns when estimating the number of groups using extended statistics (Tomas Vondra)

This led to strange estimates for queries such as `SELECT ... GROUP BY a, b, ctid`.

- Avoid divide-by-zero when estimating selectivity of a regular expression with a very long fixed prefix (Tom Lane)

This typically led to a NaN selectivity value, causing assertion failures or strange planner behavior.

- Fix access-off-the-end-of-the-table error in BRIN index bitmap scans (Tomas Vondra)

If the page range size used by a BRIN index isn't a power of two, there were corner cases in which a bitmap scan could try to fetch pages past the actual end of the table, leading to “could not open file” errors.

- Fix potentially wrong answers from GIN `tsvector` index searches, when there are many matching tuples (Tom Lane)

If the number of index matches became large enough to make the bitmap holding them become lossy (a threshold that depends on `work_mem`), the code could get confused about whether rechecks are required, allowing rows to be returned that don't actually match the query.

- Fix concurrency issues with WAL segment recycling on Windows (Michael Paquier)

This reverts a change that caused intermittent “could not rename file ...: Permission denied” log messages. While there were not serious consequences, the log spam was annoying.

- Avoid incorrect timeline change while recovering uncommitted two-phase transactions from WAL (Soumyadeep Chakraborty, Jimmy Yih, Kevin Yeap)

This error could lead to subsequent WAL records being written under the wrong timeline ID, leading to consistency problems, or even complete failure to be able to restart the server, later on.

- Ensure that locks are released while shutting down a standby server's startup process (Fujii Masao)

When a standby server is shut down while still in recovery, some locks might be left held. This causes assertion failures in debug builds; it's unclear whether any serious consequence could occur in production builds.

- Fix crash when a logical replication worker does `ALTER SUBSCRIPTION REFRESH` (Peter Smith)

The core code won't do this, but a replica trigger could.

- Ensure we default to `wal_sync_method = fdatasync` on recent FreeBSD (Thomas Munro)

FreeBSD 13 supports `open_datasync`, which would normally become the default choice. However, it's unclear whether that is actually an improvement for Postgres, so preserve the existing default for now.

- Disable the `vacuum_cleanup_index_scale_factor` parameter and storage option (Peter Geoghegan)

The notion of tracking “stale” index statistics proved to interact badly with the `autovacuum_vacuum_insert_threshold` parameter, resulting in unnecessary full-index scans and consequent degradation of autovacuum performance. The latter mechanism seems superior, so remove the stale-statistics logic. The control parameter for that, `vacuum_cleanup_index_scale_factor`, will be removed entirely in v14. In v13, it remains present to avoid breaking existing configuration files, but it no longer does anything.

- Pass the correct trigger OID to object post-`alter` hooks during `ALTER CONSTRAINT` (Álvaro Herrera)

When updating trigger properties during `ALTER CONSTRAINT`, the post-`alter` hook was told that we are updating a trigger, but the constraint's OID was passed instead of the trigger's.

- Ensure we finish cleaning up when interrupted while detaching a DSM segment (Thomas Munro)

This error could result in temporary files not being cleaned up promptly after a parallel query.

- Fix assorted minor memory leaks in the server (Tom Lane, Andres Freund)
- Fix uninitialized variable in walreceiver's statistics in shared memory (Fujii Masao)

This error was harmless on most platforms, but could cause issues on platforms lacking atomic variables and/or spinlock support.

- Reduce the overhead of `dtrace` probes for LWLock operations, when `dtrace` support is compiled in but not active (Peter Eisentraut)
- Fix failure when a PL/pgSQL `DO` block makes use of both composite-type variables and transaction control (Tom Lane)

Previously, such cases led to errors about leaked tuple descriptors.

- Prevent infinite loop in `libpq` if a `ParameterDescription` message with a corrupt length is received (Tom Lane)
- When `initdb` prints instructions about how to start the server, make the path shown for `pg_ctl` use backslash separators on Windows (Nitin Jadhav)
- Fix `psql` to restore the previous behavior of `\connect service=something` (Tom Lane)

A previous bug fix caused environment variables (such as `PGPORT`) to override entries in the service file in this context. Restore the previous behavior, in which the priority is the other way around.

- Fix `psql`'s `ON_ERROR_ROLLBACK` feature to handle `COMMIT AND CHAIN` commands correctly (Arthur Nascimento)

Previously, this case failed with “savepoint “`pg_psql_temporary_savepoint`” does not exist”.

- In `psql`, avoid repeated “could not print result table” failures after the first such error (Álvaro Herrera)
- Fix race condition in detection of file modification by `psql`'s `\e` and related commands (Laurenz Albe)

A very fast typist could fool the code's file-timestamp-based detection of whether the temporary edit file was changed.

- Fix `pg_dump`'s dumping of generated columns in partitioned tables (Peter Eisentraut)

A fix introduced in the previous minor release should not be applied to partitioned tables, only traditionally-inherited tables.

- Fix missed file version check in `pg_restore` (Tom Lane)

When reading a custom-format archive from a non-seekable source, `pg_restore` neglected to check the archive version. If it was fed a newer archive version than it can support, it would fail messily later on.

- Add some more checks to `pg_upgrade` for user tables containing non-upgradable data types (Tom Lane)

Fix detection of some cases where a non-upgradable data type is embedded within a container type (such as an array or range). Also disallow upgrading when user tables contain columns of system-defined composite types, since those types' OIDs are not stable across versions.

- Fix incorrect progress-reporting calculation in `pg_checksums` (Shinya Kato)
- Fix `pg_walddump` to count `XACT` records correctly when generating per-record statistics (Kyotaro Horiguchi)
- Fix `contrib/amcheck` to not complain about the tuple flags `HEAP_XMAX_LOCK_ONLY` and `HEAP_KEYS_UPDATED` both being set (Julien Rouhaud)

This is a valid state after `SELECT FOR UPDATE`.

- Adjust `VPATH` build rules to support recent Oracle Developer Studio compiler versions (Noah Misch)
- Fix testing of PL/Python for Python 3 on Solaris (Noah Misch)

## E.15. Release 13.2

**Release date:** 2021-02-11

This release contains a variety of fixes from 13.1. For information about new features in major release 13, see [Section E.17](#).

### E.15.1. Migration to Version 13.2

A dump/restore is not required for those running 13.X.

However, see the first changelog item below concerning a possible need to update stored views. Also see the third and fourth changelog items, which describe cases in which reindexing indexes after the upgrade may be advisable.

### E.15.2. Changes

- Fix failure to check per-column `SELECT` privileges in some join queries (Tom Lane)

In some cases involving joins, the parser failed to record all the columns read by a query in the column-usage bitmaps that are used for permissions checking. Although the executor would still insist on some sort of `SELECT` privilege to run the query, this meant that a user having `SELECT` privilege on only one column of a table could nonetheless read all its columns through a suitably crafted query.

A stored view that is subject to this problem will have incomplete column-usage bitmaps, and thus permissions will still not be enforced properly on the view after updating. In installations that depend on column-level permissions for security, it is recommended to `CREATE OR REPLACE` all user-defined views to cause them to be re-parsed.

The PostgreSQL Project thanks Sven Klemm for reporting this problem. (CVE-2021-20229)

- Fix information leakage in constraint-violation error messages (Heikki Linnakangas)

If an `UPDATE` command attempts to move a row to a different partition but finds that it violates some constraint on the new partition, and the columns in that partition are in different physical positions than in the parent table, the error message could reveal the contents of columns that the user does not have `SELECT` privilege on. (CVE-2021-3393)

- Fix incorrect detection of concurrent page splits while inserting into a GiST index (Heikki Linnakangas)

Concurrent insertions could lead to a corrupt index with entries placed in the wrong pages. It's recommended to reindex any GiST index that's been subject to concurrent insertions.

- Fix `CREATE INDEX CONCURRENTLY` to wait for concurrent prepared transactions (Andrey Borodin)

At the point where `CREATE INDEX CONCURRENTLY` waits for all concurrent transactions to complete so that it can see rows they inserted, it must also wait for all prepared transactions to complete, for the same reason. Its failure to do so meant that rows inserted by prepared transactions might be omitted from the new index, causing queries relying on the index to miss such rows. In installations that have enabled prepared transactions (`max_prepared_transactions > 0`), it's recommended to reindex any concurrently-built indexes in case this problem occurred when they were built.

- Avoid crash when trying to rescan an aggregation plan node that has both hashed and sorted grouping sets (Jeff Davis)
- Fix possible incorrect query results when a hash aggregation node spills some tuples to disk (Tom Lane)

It was possible for aggregation grouping values to be replaced by nulls when the tuples are read back in, leading to wrong answers.

- Fix edge case in incremental sort (Neil Chen)

If the last tuple of a sort batch chanced to be the first tuple of the next group of already-sorted tuples, the code did the wrong thing. This could lead to “retrieved too many tuples in a bounded sort” error messages, or to silently-wrong sorting results.

- Avoid crash when a `CALL` or `DO` statement that performs a transaction rollback is executed via extended query protocol (Thomas Munro, Tom Lane)

In PostgreSQL 13, this case reliably caused a null-pointer dereference. In earlier versions the bug seems to have no visible symptoms, but it's not quite clear that it could never cause a problem.

- Avoid unnecessary errors with `BEFORE UPDATE` triggers on partitioned tables (Álvaro Herrera)

A `BEFORE UPDATE FOR EACH ROW` trigger that modified the row in any way prevented `UPDATE` from moving the row to another partition when needed; but there is no longer any reason for this restriction.

- Fix partition pruning logic to handle asymmetric hash partition sets (Tom Lane)

If a hash-partitioned table has unequally-sized partitions (that is, varying modulus values), or it lacks partitions for some remainder values, then the planner's pruning logic could mistakenly conclude that some partitions don't need to be scanned, leading to failure to find rows that the query should find.

- Avoid incorrect results when `WHERE CURRENT OF` is applied to a cursor whose plan contains a MergeAppend node (Tom Lane)

This case is unsupported (in general, a cursor using `ORDER BY` is not guaranteed to be simply updatable); but the code previously did not reject it, and could silently give false matches.

- Fix crash when `WHERE CURRENT OF` is applied to a cursor whose plan contains a custom scan node (David Geier)
- Fix planner's mishandling of placeholders whose evaluation should be delayed by an outer join (Tom Lane)

This occurs in particular with trivial subqueries containing lateral references to outer-join outputs. The mistake could result in a malformed plan. The known cases trigger a “failed to assign all NestLoopParams to plan nodes” error, but other symptoms may be possible.

- Fix planner's handling of placeholders during removal of useless RESULT RTEs (Tom Lane)

This oversight could lead to “no relation entry for relid *N*” planner errors.

- Fix planner's handling of a placeholder that is computed at some join level and used only at that same level (Tom Lane)

This oversight could lead to “failed to build any *N*-way joins” planner errors.

- Consider unsorted subpaths when planning a Gather Merge operation (James Coleman)

It's possible to use such a path by adding an explicit Sort node, and in some cases that gives rise to a superior plan.

- Do not consider `ORDER BY` expressions involving parallel-restricted functions or set-returning functions when trying to parallelize sorts (James Coleman)

Such cases cannot safely be pushed into worker processes, but the incremental sort feature accidentally made us consider them.

- Be more careful about whether index AMs support mark/restore (Andrew Gierth)

This prevents errors about missing support functions in rare edge cases.

- Fix overestimate of the amount of shared memory needed for parallel queries (Takayuki Tsunakawa)
- Fix `ALTER DEFAULT PRIVILEGES` to handle duplicated arguments safely (Michael Paquier)

Duplicate role or schema names within the same command could lead to “tuple already updated by self” errors or unique-constraint violations.

- Flush ACL-related caches when `pg_authid` changes (Noah Misch)

This change ensures that permissions-related decisions will promptly reflect the results of `ALTER ROLE ... [NO] INHERIT`.

- Fix failure to detect “snapshot too old” conditions in tables rewritten in the current transaction (Kyotaro Horiguchi, Noah Misch)

This is only a hazard when `wal_level` is set to `minimal` and the rewrite is performed by `ALTER TABLE SET TABLESPACE`.

- Fix spurious failure of `CREATE PUBLICATION` when applied to a table created or rewritten in the current transaction (Kyotaro Horiguchi)

This is only a hazard when `wal_level` is set to `minimal`.

- Prevent misprocessing of ambiguous `CREATE TABLE LIKE` clauses (Tom Lane)

A `LIKE` clause is re-examined after initial creation of the new table, to handle importation of indexes and such. It was possible for this re-examination to find a different table of the same name, causing unexpected behavior; one example is where the new table is a temporary table of the same name as the `LIKE` target.

- Rearrange order of operations in `CREATE TABLE LIKE` so that indexes are cloned before building foreign key constraints (Tom Lane)

This fixes the case where a self-referential foreign key constraint declared in the outer `CREATE TABLE` depends on an index that's coming from the `LIKE` clause.

- Disallow `CREATE STATISTICS` on system catalogs (Tomas Vondra)
- Disallow converting an inheritance child table to a view (Tom Lane)
- Ensure that disk space allocated for a dropped relation is released promptly at commit (Thomas Munro)

Previously, if the dropped relation spanned multiple 1GB segments, only the first segment was truncated immediately. Other segments were simply unlinked, which doesn't authorize the kernel to release the storage so long as any other backends still have the files open.

- Prevent dropping a tablespace that is referenced by a partitioned relation, but is not used for any actual storage (Alvaro Herrera)

Previously this was allowed, but subsequent operations on the partitioned relation would fail.

- Fix progress reporting for `CLUSTER` (Matthias van de Meent)
- Fix handling of backslash-escaped multibyte characters in `COPY FROM` (Heikki Linnakangas)

A backslash followed by a multibyte character was not handled correctly. In some client character encodings, this could lead to misinterpreting part of a multibyte character as a field separator or end-of-copy-data marker.

- Avoid preallocating executor hash tables in `EXPLAIN` without `ANALYZE` (Alexey Bashtanov)
- Fix recently-introduced race condition in `LISTEN/NOTIFY` queue handling (Tom Lane)

A newly-listening backend could attempt to read SLRU pages that were in process of being truncated, possibly causing an error.

- Allow the `jsonb` concatenation operator to handle all combinations of JSON data types (Tom Lane)

We can concatenate two JSON objects or two JSON arrays. Handle other cases by wrapping non-array inputs in one-element arrays, then performing an array concatenation. Previously, some combinations of inputs followed this rule but others arbitrarily threw an error.

- Fix use of uninitialized value while parsing a `*` quantifier in a BRE-mode regular expression (Tom Lane)

This error could cause the quantifier to act non-greedy, that is behave like a `*?` quantifier would do in full regular expressions.

- Fix numeric `power()` for the case where the exponent is exactly `INT_MIN` (-2147483648) (Dean Rasheed)

Previously, a result with no significant digits was produced.

- Fix integer-overflow cases in `substring()` functions (Tom Lane, Pavel Stehule)

If the specified starting index and length overflow an integer when added together, `substring()` misbehaved, either throwing a bogus “negative substring length” error for a case that should succeed, or failing to complain that a negative length is negative (and instead returning the whole string, in most cases).

- Prevent possible data loss from incorrect detection of the wraparound point of an SLRU log (Noah Misch)

The wraparound point typically falls in the middle of a page, which must be rounded off to a page boundary, and that was not done correctly. No issue could arise unless an installation had gotten to within one page of SLRU overflow, which is unlikely in a properly-functioning system. If this did happen, it would manifest in later “apparent wraparound” or “could not access status of transaction” errors.

- Fix WAL-reading logic to handle timeline switches correctly (Kyotaro Horiguchi, Fujii Masao)

Previously, if WAL archiving is enabled, a standby could fail to follow a primary running on a newer timeline, with errors like “requested WAL segment has already been removed”.

- Fix memory leak in walsender processes while sending new snapshots for logical decoding (Amit Kapila)
- Fix relation cache leak in walsender processes while sending row changes via the root of a partitioned relation during logical replication (Amit Langote, Mark Zhao)
- Fix walsender to accept additional commands after terminating replication (Jeff Davis)
- Ensure detection of deadlocks between hot standby backends and the startup (WAL-application) process (Fujii Masao)

The startup process did not run the deadlock detection code, so that in situations where the startup process is last to join a circular wait situation, the deadlock might never be recognized.

- Fix possible failure to detect recovery conflicts while deleting an index entry that references a HOT chain (Peter Geoghegan)

The code failed to traverse the HOT chain and might thus compute a too-old XID horizon, which could lead to incorrect conflict processing in hot standby. The practical impact of this bug is limited; in most cases the correct XID horizon would be found anyway from nearby operations.

- Ensure that a nonempty value of `krb_server_keyfile` always overrides any setting of `KRB5_KTNAME` in the server's environment (Tom Lane)

Previously, which setting took precedence depended on whether the client requests GSS encryption.

- In server log messages about failing to match connections to `pg_hba.conf` entries, include details about whether GSS encryption has been activated (Kyotaro Horiguchi, Tom Lane)

This is relevant data if `hostgssenc` or `hostnogssenc` entries exist.

- Fix assorted issues in server's support for GSS encryption (Tom Lane)

Remove pointless restriction that only GSS authentication can be used on a GSS-encrypted connection. Add GSS encryption information to connection-authorized log messages. Include GSS-related space when computing the required size of shared memory (this omission could have caused problems with very high `max_connections` settings). Avoid possible infinite recursion when reporting an unrecoverable GSS encryption error.

- Ensure that unserviced requests for background workers are cleaned up when the postmaster begins a “smart” or “fast” shutdown sequence (Tom Lane)

Previously, there was a race condition whereby a child process that had requested a background worker just before shutdown could wait indefinitely, preventing shutdown from completing.

- Fix portability problem in parsing of `recovery_target_xid` values (Michael Paquier)

The target XID is potentially 64 bits wide, but it was parsed with `strtoul()`, causing misbehavior on platforms where `long` is 32 bits (such as Windows).

- Avoid trying to use parallel index build in a standalone backend (Yulin Pei)
- Allow index AMs to support included columns without necessarily supporting multiple key columns (Tom Lane)
- While taking a base backup, avoid executing any SHA256 code if a backup manifest is not needed (Michael Paquier)

When using OpenSSL operating in FIPS mode, SHA256 hashing is rejected, leading to an error. This change makes it possible to take a base backup on such a platform, so long as `--no-manifest` is specified.

- Avoid assertion failure during parallel aggregation of an aggregate with a non-strict deserialization function (Andrew Gierth)

No such aggregate functions exist in core PostgreSQL, but some extensions such as PostGIS provide some. The mistake is harmless anyway in a non-assert build.

- Avoid assertion failure in `pg_get_functiondef()` when examining a function with a `TRANSFORM` option (Tom Lane)
- Fix data structure misallocation in PL/pgSQL's `CALL` statement (Tom Lane)

A `CALL` in a PL/pgSQL procedure, to another procedure that has `OUT` parameters, would fail if the called procedure did a `COMMIT` or `ROLLBACK`.

- In `libpq`, do not skip trying SSL after GSS encryption (Tom Lane)

If we successfully made a GSS-encrypted connection, but then failed during authentication, we would fall back to an unencrypted connection rather than next trying an SSL-encrypted connection. This could lead to unexpected connection failure, or to silently getting an unencrypted connection where an encrypted one is expected. Fortunately, GSS encryption could only succeed if both client and server hold valid tickets in the same Kerberos infrastructure. It seems unlikely for that to be true in an environment that requires SSL encryption instead.

- Make `libpq`'s `PQconndefaults()` function report the correct default value for `channel_binding` (Daniele Varrazzo)
- In `psql`, re-allow including a password in a `connection_string` argument of a `\connect` command (Tom Lane)

This used to work, but a recent bug fix caused the password to be ignored (resulting in prompting for a password).

- In `psql`'s `\d` commands, don't truncate the display of column default values (Tom Lane)

Formerly, they were arbitrarily truncated at 128 characters.

- Fix assorted bugs in `psql`'s `\help` command (Kyotaro Horiguchi, Tom Lane)

`\help` with two argument words failed to find a command description using only the first word, for example `\help reset all` should show the help for `RESET` but did not. Also, `\help` often failed to invoke the pager when it should. It also leaked memory.

- Fix `pg_dump`'s dumping of inherited generated columns (Peter Eisentraut)

The previous behavior resulted in (harmless) errors during restore.

- In `pg_dump`, ensure that the restore script runs `ALTER PUBLICATION ADD TABLE` commands as the owner of the publication, and similarly runs `ALTER INDEX ATTACH PARTITION` commands as the owner of the partitioned index (Tom Lane)

Previously, these commands would be run by the role that started the restore script; which will usually work, but in corner cases that role might not have adequate permissions.

- Fix `pg_dump` to handle `WITH GRANT OPTION` in an extension's initial privileges (Noah Misch)

If an extension's script creates an object and grants privileges on it with grant option, then later the user revokes such privileges, `pg_dump` would generate incorrect SQL for reproducing the situation. (Few if any extensions do this today.)

- In `pg_rewind`, ensure that all WAL is accounted for when rewinding a standby server (Ian Barwick, Heikki Linnakangas)
- In `pgbench`, disallow a digit as the first character of a variable name (Fabien Coelho)

This prevents trying to substitute variables into timestamp literal values, which may contain strings like `12:34`.

- Report the correct database name in connection failure error messages from some client programs (Álvaro Herrera)

If the database name was defaulted rather than given on the command line, `pg_dumpall`, `pgbench`, `oid2name`, and `vacuumlo` would produce misleading error messages after a connection failure.

- Fix memory leak in `contrib/auto_explain` (Japin Li)

Memory consumed while producing the `EXPLAIN` output was not freed until the end of the current transaction (for a top-level statement) or the end of the surrounding statement (for a nested statement). This was particularly a problem with `log_nested_statements` enabled.

- In `contrib/postgres_fdw`, avoid leaking open connections to remote servers when a user mapping or foreign server object is dropped (Bharath Rupireddy)

Open connections that depend on a dropped user mapping or foreign server can no longer be referenced, but formerly they were kept around anyway for the duration of the local session.

- Fix faulty assertion in `contrib/postgres_fdw` (Etsuro Fujita)
- In `contrib/pgcrypto`, check for error returns from OpenSSL's EVP functions (Michael Paquier)

We do not really expect errors here, but this change silences warnings from static analysis tools.

- Make `contrib/pg_prewarm` more robust when the cluster is shut down before prewarming is complete (Tom Lane)

Previously, `autoprewarm` would rewrite its status file with only the block numbers that it had managed to load so far, thus perhaps largely disabling the prewarm functionality in the next startup. Instead, suppress status file updates until the initial loading pass is complete.

- In `contrib/pg_trgm`'s GiST index support, avoid crash in the rare case that `picksplit` is called on exactly two index items (Andrew Gierth, Alexander Korotkov)
- Fix miscalculation of timeouts in `contrib/pg_prewarm` and `contrib/postgres_fdw` (Alexey Kondratov, Tom Lane)

The main loop in `contrib/pg_prewarm`'s `autoprewarm` parent process underestimated its desired sleep time by a factor of 1000, causing it to consume much more CPU than intended. When waiting for a result from a remote server, `contrib/postgres_fdw` overestimated the desired timeout by a factor of 1000 (though this error had been mitigated by imposing a clamp to 60 seconds).

Both of these errors stemmed from incorrectly converting seconds-and-microseconds to milliseconds. Introduce a new API `TimestampDifferenceMilliseconds()` to make it easier to get this right in the future.

- Improve `configure`'s heuristics for selecting `PG_SYSROOT` on macOS (Tom Lane)

The new method is more likely to produce desirable results when Xcode is newer than the underlying operating system. Choosing a sysroot that does not match the OS version may result in nonfunctional executables.

- While building on macOS, specify `-isysroot` in link steps as well as compile steps (James Hilliard)

This likewise improves the results when Xcode is out of sync with the operating system.

- Fix JIT compilation to be compatible with LLVM 11 and LLVM 12 (Andres Freund)
- Fix potential mishandling of references to boolean variables in JIT expression compilation (Andres Freund)

No field reports attributable to this have been seen, but it seems likely that it could cause problems on some architectures.

- Fix compile failure with ICU 68 and later (Tom Lane)
- Avoid `memcpy()` with a NULL source pointer and zero count during partitioned index creation (Álvaro Herrera)

While such a call is not known to cause problems in itself, some compilers assume that the arguments of `memcpy()` are never NULL, which could result in incorrect optimization of nearby code.

- Update time zone data files to tzdata release 2021a for DST law changes in Russia (Volgograd zone) and South Sudan, plus historical corrections for Australia, Bahamas, Belize, Bermuda, Ghana, Israel, Kenya, Nigeria, Palestine, Seychelles, and Vanuatu.

Notably, the Australia/Currie zone has been corrected to the point where it is identical to Australia/Hobart.

## E.16. Release 13.1

**Release date:** 2020-11-12

This release contains a variety of fixes from 13.0. For information about new features in major release 13, see [Section E.17](#).

### E.16.1. Migration to Version 13.1

A dump/restore is not required for those running 13.X.

### E.16.2. Changes

- Block `DECLARE CURSOR ... WITH HOLD` and firing of deferred triggers within index expressions and materialized view queries (Noah Misch)

This is essentially a leak in the “security restricted operation” sandbox mechanism. An attacker having permission to create non-temporary SQL objects could parlay this leak to execute arbitrary SQL code as a superuser.

The PostgreSQL Project thanks Etienne Stalmans for reporting this problem. (CVE-2020-25695)

- Fix usage of complex connection-string parameters in `pg_dump`, `pg_restore`, `clusterdb`, `reindexdb`, and `vacuumdb` (Tom Lane)

The `-d` parameter of `pg_dump` and `pg_restore`, or the `--maintenance-db` parameter of the other programs mentioned, can be a “connection string” containing multiple connection parameters rather than just a database name. In cases where these programs need to initiate additional connections, such as parallel processing or processing of multiple databases, the connection string was forgotten and just the basic connection parameters (database name, host, port, and username) were used for the additional connections. This could lead to connection failures if the connection

string included any other essential information, such as non-default SSL or GSS parameters. Worse, the connection might succeed but not be encrypted as intended, or be vulnerable to man-in-the-middle attacks that the intended connection parameters would have prevented. (CVE-2020-25694)

- When `psql's \connect` command re-uses connection parameters, ensure that all non-overridden parameters from a previous connection string are re-used (Tom Lane)

This avoids cases where reconnection might fail due to omission of relevant parameters, such as non-default SSL or GSS options. Worse, the reconnection might succeed but not be encrypted as intended, or be vulnerable to man-in-the-middle attacks that the intended connection parameters would have prevented. This is largely the same problem as just cited for `pg_dump` et al, although `psql's` behavior is more complex since the user may intentionally override some connection parameters. (CVE-2020-25694)

- Prevent `psql's \gset` command from modifying specially-treated variables (Noah Misch)

`\gset` without a prefix would overwrite whatever variables the server told it to. Thus, a compromised server could set specially-treated variables such as `PROMPT1`, giving the ability to execute arbitrary shell code in the user's session.

The PostgreSQL Project thanks Nick Cleaton for reporting this problem. (CVE-2020-25696)

- Fix unintended breakage of the replication protocol (Álvaro Herrera)

A `walsender` reports two command-completion events for `START_REPLICATION`. This was undocumented and apparently unintentional; so we failed to notice that a late 13.0 change removed the duplicate event. However it turns out that `walreceivers` require the extra event in some code paths. The most practical fix is to decree that the extra event is part of the protocol and resume generating it.

- Ensure that SLRU directories are properly `fsync'd` during checkpoints (Thomas Munro)

This prevents possible data loss in a subsequent operating system crash.

- Fix `ALTER ROLE` for users with the `BYPASSRLS` attribute (Tom Lane, Stephen Frost)

The `BYPASSRLS` attribute is only allowed to be changed by superusers, but other `ALTER ROLE` operations, such as password changes, should be allowed with only ordinary permission checks. The previous coding erroneously restricted all changes on such a role to superusers.

- Disallow `ALTER TABLE ONLY ... DROP EXPRESSION` when there are child tables (Peter Eisentraut)

The current implementation cannot handle this case correctly, so just forbid it for now.

- Ensure that `ALTER TABLE ONLY ... ENABLE/DISABLE TRIGGER` does not recurse to child tables (Álvaro Herrera)

Previously the `ONLY` flag was ignored.

- Allow `LOCK TABLE` to succeed on a self-referential view (Tom Lane)

It previously threw an error complaining about infinite recursion, but there seems no need to disallow the case.

- Retain statistics about an index across `REINDEX CONCURRENTLY` (Michael Paquier, Fabrízio de Royes Mello)

Non-concurrent reindexing has always preserved such statistics.

- Fix incorrect progress reporting from `REINDEX CONCURRENTLY` (Matthias van de Meent, Michael Paquier)

- Ensure that `GENERATED` columns are updated when the column(s) they depend on are updated via a rule or an updatable view (Tom Lane)

This fix also takes care of possible failure to fire a column-specific trigger in such cases.

- Fix failures with collation-dependent partition bound expressions (Tom Lane)
- Support hashing of text arrays (Peter Eisentraut)

Array hashing failed if the array element type is collatable. Notably, this prevented using hash partitioning with a text array column as partition key.

- Prevent internal overflows in cross-type datetime comparisons (Nikita Glukhov, Alexander Korotkov, Tom Lane)

Previously, comparing a date to a timestamp would fail if the date is past the valid range for timestamps. There were also corner cases involving overflow of close-to-the-limit timestamp values during timezone rotation.

- Fix off-by-one conversion of negative years to BC dates in `to_date()` and `to_timestamp()` (Dar Alathar-Yemen, Tom Lane)

Also, arrange for the combination of a negative year and an explicit “BC” marker to cancel out and produce AD.

- Allow the `jsonpath.datetime()` method to accept ISO 8601-format timestamps (Nikita Glukhov)

This is not required by SQL, but it seems appropriate since our `to_json()` functions generate that timestamp format for Javascript compatibility.

- Ensure that standby servers will archive WAL timeline history files when `archive_mode` is set to `always` (Grigory Smolkin, Fujii Masao)

This oversight could lead to failure of subsequent PITR recovery attempts.

- Fix edge cases in detecting premature death of the postmaster on platforms that use `kqueue()` (Thomas Munro)
- Avoid generating an incorrect incremental-sort plan when the sort key is a volatile expression (James Coleman)
- Fix possible crash when considering partition-wise joins during GEQO planning (Tom Lane)
- Fix possible infinite loop or corrupted output data in TOAST decompression (Tom Lane)
- Fix counting of the number of entries in B-tree indexes during cleanup-only `VACUUMS` (Peter Geoghegan)
- Ensure that data is detoasted before being inserted into a BRIN index (Tomas Vondra)

Index entries are not supposed to contain out-of-line TOAST pointers, but BRIN didn't get that memo. This could lead to errors like “missing chunk number 0 for toast value NNN”. (If you are faced with such an error from an existing index, `REINDEX` should be enough to fix it.)

- Fix buffered GiST index builds to work when the index has included columns (Pavel Borisov)
- Fix unportable use of `getnameinfo()` in `pg_hba_file_rules` view (Tom Lane)

On FreeBSD 11, and possibly other platforms, the view's `address` and `netmask` columns were always null due to this error.

- Avoid crash if `debug_query_string` is NULL when starting a parallel worker (Noah Misch)
- Avoid failures when a `BEFORE ROW UPDATE` trigger returns the “old” row of a table having dropped or “missing” columns (Amit Langote, Tom Lane)

This method of suppressing an update could result in crashes, unexpected `CHECK` constraint failures, or incorrect `RETURNING` output, because “missing” columns would read as NULLs for those purposes. (A column is “missing” for this purpose if it was added by `ALTER TABLE ADD COLUMN` with a non-NULL, but constant, default value.) Dropped columns could cause trouble as well.

- Fix `EXPLAIN`'s output for incremental sort plans to have correct tag nesting in XML output mode (Daniel Gustafsson)

- Avoid unnecessary failure when transferring very large payloads through shared memory queues (Markus Wanner)

- Fix omission of result data type coercion in some cases in SQL-language functions (Tom Lane)

This could lead to wrong results or crashes, depending on the data types involved.

- Fix incorrect handling of template function attributes in JIT code generation (Andres Freund)

This has been shown to cause crashes on `s390x`, and very possibly there are other cases on other platforms.

- Improve code generated for `compare_exchange` and `fetch_add` operations on PPC (Noah Misch)
- Fix relation cache memory leaks with RLS policies (Tom Lane)
- Fix edge-case memory leak in `index_get_partition()` (Justin Pryzby)
- Fix small memory leak when `SIGHUP` processing decides that a new GUC variable value cannot be applied without a restart (Tom Lane)
- Fix memory leaks in PL/pgsql's `CALL` processing (Pavel Stehule, Tom Lane)
- In `libpq` for Windows, call `WSAStartup()` once per process and `WSACleanup()` not at all (Tom Lane, Alexander Lakhin)

Previously, `libpq` invoked `WSAStartup()` at connection start and `WSACleanup()` at connection cleanup. However, it appears that calling `WSACleanup()` can interfere with other program operations; notably, we have observed rare failures to emit expected output to `stdout`. There appear to be no ill effects from omitting the call, so do that. (This also eliminates a performance issue from repeated DLL loads and unloads when a program performs a series of database connections.)

- Fix `ecpg` library's per-thread initialization logic for Windows (Tom Lane, Alexander Lakhin)

Multi-threaded `ecpg` applications could suffer rare misbehavior due to incorrect locking.

- Fix `ecpg`'s mis-processing of `B' . . . '` and `X' . . . '` literals (Shenhao Wang)
- On Windows, make `psql` read the output of a backtick command in text mode, not binary mode (Tom Lane)

This ensures proper handling of newlines.

- Ensure that `pg_dump` collects per-column information about extension configuration tables (Fabrício de Royes Mello, Tom Lane)

Failure to do this led to crashes when specifying `--inserts`, or underspecified (though usually correct) `COPY` commands when using `COPY` to reload the tables' data.

- Make `pg_upgrade` check for pre-existence of tablespace directories in the target cluster (Bruce Momjian)
- Fix potential memory leak in `contrib/pgcrypto` (Michael Paquier)
- Add check for an unlikely failure case in `contrib/pgcrypto` (Daniel Gustafsson)
- Fix recently-added `timetz` test case so it works when the USA is not observing daylight savings time (Tom Lane)
- Update time zone data files to `tzdata` release 2020d for DST law changes in Fiji, Morocco, Palestine, the Canadian Yukon, Macquarie Island, and Casey Station (Antarctica); plus historical corrections for France, Hungary, Monaco, and Palestine.
- Sync our copy of the timezone library with IANA `tzcode` release 2020d (Tom Lane)

This absorbs upstream's change of `zic`'s default output option from "fat" to "slim". That's just cosmetic for our purposes, as we continue to select the "fat" mode in pre-v13 branches. This change also ensures that `strftime()` does not change `errno` unless it fails.

## E.17. Release 13

**Release date:** 2020-09-24

### E.17.1. Overview

PostgreSQL 13 contains many new features and enhancements, including:

- Space savings and performance gains from de-duplication of B-tree index entries
- Improved performance for queries that use aggregates or partitioned tables
- Better query planning when using extended statistics
- Parallelized vacuuming of indexes
- Incremental sorting

The above items and other new features of PostgreSQL 13 are explained in more detail in the sections below.

### E.17.2. Migration to Version 13

A dump/restore using [pg\\_dumpall](#) or use of [pg\\_upgrade](#) or logical replication is required for those wishing to migrate data from any previous release. See [Section 17.6](#) for general information on migrating to new major releases.

Version 13 contains a number of changes that may affect compatibility with previous releases. Observe the following incompatibilities:

- Change `SIMILAR TO ... ESCAPE NULL` to return NULL (Tom Lane)

This new behavior matches the SQL specification. Previously a null ESCAPE value was taken to mean using the default escape string (a backslash character). This also applies to `substring(text FROM pattern ESCAPE text)`. The previous behavior has been retained in old views by keeping the original function unchanged.

- Make `json[b]_to_tsvector()` fully check the spelling of its `string` option (Dominik Czarnota)
- Change the way non-default `effective_io_concurrency` values affect concurrency (Thomas Munro)

Previously, this value was adjusted before setting the number of concurrent requests. The value is now used directly. Conversion of old values to new ones can be done using:

```
SELECT round(sum(OLDVALUE / n::float)) AS newvalue FROM generate_series(1, OLDVALUE)
s(n);
```

- Prevent display of auxiliary processes in `pg_stat_ssl` and `pg_stat_gssapi` system views (Euler Taveira)

Queries that join these views to `pg_stat_activity` and wish to see auxiliary processes will need to use left joins.

- Rename various `wait events` to improve consistency (Fujii Masao, Tom Lane)
- Fix `ALTER FOREIGN TABLE ... RENAME COLUMN` to return a more appropriate command tag (Fujii Masao)

Previously it returned `ALTER TABLE`; now it returns `ALTER FOREIGN TABLE`.

- Fix `ALTER MATERIALIZED VIEW ... RENAME COLUMN` to return a more appropriate command tag (Fujii Masao)

Previously it returned `ALTER TABLE`; now it returns `ALTER MATERIALIZED VIEW`.

- Rename configuration parameter `wal_keep_segments` to `wal_keep_size` (Fujii Masao)

This determines how much WAL to retain for standby servers. It is specified in megabytes, rather than number of files as with the old parameter. If you previously used `wal_keep_segments`, the following formula will give you an approximately equivalent setting:

```
wal_keep_size = wal_keep_segments * wal_segment_size (typically 16MB)
```

- Remove support for defining [operator classes](#) using pre-PostgreSQL 8.0 syntax (Daniel Gustafsson)
- Remove support for defining [foreign key constraints](#) using pre-PostgreSQL 7.3 syntax (Daniel Gustafsson)
- Remove support for "opaque" [pseudo-types](#) used by pre-PostgreSQL 7.3 servers (Daniel Gustafsson)
- Remove support for upgrading unpackaged (pre-9.1) extensions (Tom Lane)

The `FROM` option of `CREATE EXTENSION` is no longer supported. Any installations still using unpackaged extensions should upgrade them to a packaged version before updating to PostgreSQL 13.

- Remove support for `posixrules` files in the timezone database (Tom Lane)

IANA's timezone group has deprecated this feature, meaning that it will gradually disappear from systems' timezone databases over the next few years. Rather than have a behavioral change appear unexpectedly with a timezone data update, we have removed PostgreSQL's support for this feature as of version 13. This affects only the behavior of [POSIX-style time zone specifications](#) that lack an explicit daylight savings transition rule; formerly the transition rule could be determined by installing a custom `posixrules` file, but now it is hard-wired. The recommended fix for any affected installations is to start using a geographical time zone name.

- In `ltree`, when an `lquery` pattern contains adjacent asterisks with braces, e.g., `*{2}.*{3}`, properly interpret that as `*{5}` (Nikita Glukhov)
- Fix `pageinspect`'s `bt_metap()` to return more appropriate data types that are less likely to overflow (Peter Geoghegan)

## E.17.3. Changes

Below you will find a detailed account of the changes between PostgreSQL 13 and the previous major release.

### E.17.3.1. Server

#### E.17.3.1.1. Partitioning

- Allow [pruning](#) of partitions to happen in more cases (Yuzuko Hosoya, Amit Langote, Álvaro Herrera)
- Allow [partitionwise joins](#) to happen in more cases (Ashutosh Bapat, Etsuro Fujita, Amit Langote, Tom Lane)

For example, partitionwise joins can now happen between partitioned tables even when their partition bounds do not match exactly.

- Support row-level `BEFORE` [triggers](#) on partitioned tables (Álvaro Herrera)

However, such a trigger is not allowed to change which partition is the destination.

- Allow partitioned tables to be logically replicated via [publications](#) (Amit Langote)

Previously, partitions had to be replicated individually. Now a partitioned table can be published explicitly, causing all its partitions to be published automatically. Addition/removal of a partition causes it to be likewise added to or removed from the publication. The `CREATE PUBLICATION` option `publish_via_partition_root` controls whether changes to partitions are published as their own changes or their parent's.

- Allow logical replication into partitioned tables on subscribers (Amit Langote)  
Previously, subscribers could only receive rows into non-partitioned tables.
- Allow whole-row variables (that is, `table.*`) to be used in partitioning expressions (Amit Langote)

#### E.17.3.1.2. Indexes

- More efficiently store [duplicates](#) in B-tree indexes (Anastasia Lubennikova, Peter Geoghegan)  
This allows efficient B-tree indexing of low-cardinality columns by storing duplicate keys only once. Users upgrading with `pg_upgrade` will need to use `REINDEX` to make an existing index use this feature.
- Allow [GiST](#) and [SP-GiST](#) indexes on `box` columns to support `ORDER BY box <-> point` queries (Nikita Glukhov)
- Allow [GIN](#) indexes to more efficiently handle `!` (NOT) clauses in `tsquery` searches (Nikita Glukhov, Alexander Korotkov, Tom Lane, Julien Rouhaud)
- Allow [index operator classes](#) to take parameters (Nikita Glukhov)
- Allow `CREATE INDEX` to specify the GiST signature length and maximum number of integer ranges (Nikita Glukhov)

Indexes created on four and eight-byte [integer array](#), [tsvector](#), [pg\\_trgm](#), [ltree](#), and [hstore](#) columns can now control these GiST index parameters, rather than using the defaults.

- Prevent indexes that use non-default collations from being [added](#) as a table's unique or primary key constraint (Tom Lane)

The index's collation must match that of the underlying column, but `ALTER TABLE` previously failed to check this.

#### E.17.3.1.3. Optimizer

- Improve the optimizer's [selectivity](#) estimation for containment/match operators (Tom Lane)
- Allow setting the [statistics target](#) for [extended statistics](#) (Tomas Vondra)

This is controlled with the new command option `ALTER STATISTICS ... SET STATISTICS`. Previously this was computed based on more general statistics target settings.

- Allow use of multiple extended statistics objects in a single query (Tomas Vondra)
- Allow use of extended statistics objects for OR clauses and [IN/ANY](#) constant lists (Pierre Ducroquet, Tomas Vondra)
- Allow functions in `FROM` clauses to be pulled up (inlined) if they evaluate to constants (Alexander Kuzmenkov, Aleksandr Parfenov)

#### E.17.3.1.4. General Performance

- Implement [incremental sorting](#) (James Coleman, Alexander Korotkov, Tomas Vondra)

If an intermediate query result is known to be sorted by one or more leading keys of a required sort ordering, the additional sorting can be done considering only the remaining keys, if the rows are sorted in batches that have equal leading keys.

If necessary, this can be controlled using `enable_incremental_sort`.

- Improve the performance of sorting [inet](#) values (Brandur Leach)
- Allow [hash aggregation](#) to use disk storage for large aggregation result sets (Jeff Davis)

Previously, hash aggregation was avoided if it was expected to use more than `work_mem` memory. Now, a hash aggregation plan can be chosen despite that. The hash table will be spilled to disk if it exceeds `work_mem` times `hash_mem_multiplier`.

This behavior is normally preferable to the old behavior, in which once hash aggregation had been chosen, the hash table would be kept in memory no matter how large it got — which could be very large if the planner had misestimated. If necessary, behavior similar to that can be obtained by increasing `hash_mem_multiplier`.

- Allow inserts, not only updates and deletes, to trigger vacuuming activity in `autovacuum` (Laurenz Albe, Darafei Praliaskouski)

Previously, insert-only activity would trigger auto-analyze but not auto-vacuum, on the grounds that there could not be any dead tuples to remove. However, a vacuum scan has other useful side-effects such as setting page-all-visible bits, which improves the efficiency of index-only scans. Also, allowing an insert-only table to receive periodic vacuuming helps to spread out the work of “freezing” old tuples, so that there is not suddenly a large amount of freezing work to do when the entire table reaches the anti-wraparound threshold all at once.

If necessary, this behavior can be adjusted with the new parameters `autovacuum_vacuum_insert_threshold` and `autovacuum_vacuum_insert_scale_factor`, or the equivalent table storage options.

- Add `maintenance_io_concurrency` parameter to control I/O concurrency for maintenance operations (Thomas Munro)
- Allow WAL writes to be skipped during a transaction that creates or rewrites a relation, if `wal_level` is `minimal` (Kyotaro Horiguchi)

Relations larger than `wal_skip_threshold` will have their files `fsync`'ed rather than generating WAL. Previously this was done only for `COPY` operations, but the implementation had a bug that could cause data loss during crash recovery.

- Improve performance when replaying `DROP DATABASE` commands when many tablespaces are in use (Fujii Masao)
- Improve performance for `truncation` of very large relations (Kirk Jamison)
- Improve retrieval of the leading bytes of `TOAST`'ed values (Binguo Bao, Andrey Borodin)

Previously, compressed out-of-line `TOAST` values were fully fetched even when it's known that only some leading bytes are needed. Now, only enough data to produce the result is fetched.

- Improve performance of `LISTEN/NOTIFY` (Martijn van Oosterhout, Tom Lane)
- Speed up conversions of integers to text (David Fetter)
- Reduce memory usage for query strings and extension scripts that contain many SQL statements (Amit Langote)

#### **E.17.3.1.5. Monitoring**

- Allow `EXPLAIN`, `auto_explain`, `autovacuum`, and `pg_stat_statements` to track WAL usage statistics (Kirill Bychik, Julien Rouhaud)
- Allow a sample of SQL statements, rather than all statements, to be logged (Adrien Nayrat)

A `log_statement_sample_rate` fraction of those statements taking more than `log_min_duration_sample` duration will be logged.

- Add the backend type to `csvlog` and optionally `log_line_prefix` log output (Peter Eisentraut)
- Improve control of prepared statement parameter logging (Alexey Bashtanov, Álvaro Herrera)

The GUC setting `log_parameter_max_length` controls the maximum length of parameter values output during logging of non-error statements, while `log_parameter_max_length_on_error` does the same for logging of statements with errors. Previously, prepared statement parameters were never logged during errors.

- Allow function call backtraces to be logged after errors (Peter Eisentraut, Álvaro Herrera)

The new parameter [backtrace\\_functions](#) specifies which C functions should generate backtraces on error.

- Make [vacuum](#) buffer counters 64-bits wide to avoid overflow (Álvaro Herrera)

#### **E.17.3.1.6. System Views**

- Add `leader_pid` to [pg\\_stat\\_activity](#) to report a parallel worker's leader process (Julien Rouhaud)
- Add system view [pg\\_stat\\_progress\\_basebackup](#) to report the progress of streaming base backups (Fujii Masao)
- Add system view [pg\\_stat\\_progress\\_analyze](#) to report [ANALYZE](#) progress (Álvaro Herrera, Tatsuro Yamada, Vinayak Pokale)
- Add system view [pg\\_shmem\\_allocations](#) to display shared memory usage (Andres Freund, Robert Haas)
- Add system view [pg\\_stat\\_slru](#) to monitor internal SLRU caches (Tomas Vondra)
- Allow [track\\_activity\\_query\\_size](#) to be set as high as 1MB (Vyacheslav Makarov)

The previous maximum was 100kB.

#### **E.17.3.1.7. Wait Events**

- Report a wait event while creating a DSM segment with `posix_fallocate()` (Thomas Munro)
- Add wait event `VacuumDelay` to report on cost-based vacuum delay (Justin Pryzby)
- Add wait events for WAL archive and recovery pause (Fujii Masao)

The new events are `BackupWaitWalArchive` and `RecoveryPause`.

- Add wait events `RecoveryConflictSnapshot` and `RecoveryConflictTablespace` to monitor recovery conflicts (Masahiko Sawada)
- Improve performance of wait events on BSD-based systems (Thomas Munro)

#### **E.17.3.1.8. Authentication**

- Allow only superusers to view the [ssl\\_passphrase\\_command](#) setting (Insung Moon)

This was changed as a security precaution.

- Change the server's default minimum TLS version for encrypted connections from 1.0 to 1.2 (Peter Eisentraut)

This choice can be controlled by [ssl\\_min\\_protocol\\_version](#).

#### **E.17.3.1.9. Server Configuration**

- Tighten rules on which utility commands are allowed in read-only transaction mode (Robert Haas)

This change also increases the number of utility commands that can run in parallel queries.

- Allow [allow\\_system\\_table\\_mods](#) to be changed after server start (Peter Eisentraut)
- Disallow non-superusers from modifying system tables when [allow\\_system\\_table\\_mods](#) is set (Peter Eisentraut)

Previously, if [allow\\_system\\_table\\_mods](#) was set at server start, non-superusers could issue `INSERT/UPDATE/DELETE` commands on system tables.

- Enable support for [Unix-domain sockets](#) on Windows (Peter Eisentraut)

#### **E.17.3.2. Streaming Replication and Recovery**

- Allow streaming replication configuration settings to be changed by reload (Sergei Kornilov)

Previously, a server restart was required to change `primary_conninfo` and `primary_slot_name`.

- Allow WAL receivers to use a temporary replication slot when a permanent one is not specified (Peter Eisentraut, Sergei Kornilov)

This behavior can be enabled using `wal_receiver_create_temp_slot`.

- Allow WAL storage for replication slots to be limited by `max_slot_wal_keep_size` (Kyotaro Horiguchi)

Replication slots that would require exceeding this value are marked invalid.

- Allow `standby promotion` to cancel any requested pause (Fujii Masao)

Previously, promotion could not happen while the standby was in paused state.

- Generate an error if recovery does not reach the specified `recovery target` (Leif Gunnar Erlandsen, Peter Eisentraut)

Previously, a standby would promote itself upon reaching the end of WAL, even if the target was not reached.

- Allow control over how much memory is used by logical decoding before it is spilled to disk (Tomas Vondra, Dilip Kumar, Amit Kapila)

This is controlled by `logical_decoding_work_mem`.

- Allow recovery to continue even if invalid pages are referenced by WAL (Fujii Masao)

This is enabled using `ignore_invalid_pages`.

### E.17.3.3. Utility Commands

- Allow `VACUUM` to process a table's indexes in parallel (Masahiko Sawada, Amit Kapila)

The new `PARALLEL` option controls this.

- Allow `FETCH FIRST` to use `WITH TIES` to return any additional rows that match the last result row (Surafel Temesgen)
- Report planning-time buffer usage in `EXPLAIN`'s `BUFFER` output (Julien Rouhaud)
- Make `CREATE TABLE LIKE` propagate a `CHECK` constraint's `NO INHERIT` property to the created table (Ildar Musin, Chris Travers)
- When using `LOCK TABLE` on a partitioned table, do not check permissions on the child tables (Amit Langote)
- Allow `OVERRIDING USER VALUE` on inserts into identity columns (Dean Rasheed)
- Add `ALTER TABLE ... DROP EXPRESSION` to allow removing the `GENERATED` property from a column (Peter Eisentraut)
- Fix bugs in multi-step `ALTER TABLE` commands (Tom Lane)

`IF NOT EXISTS` clauses now work as expected, in that derived actions (such as index creation) do not execute if the column already exists. Also, certain cases of combining related actions into one `ALTER TABLE` now work when they did not before.

- Add `ALTER VIEW` syntax to rename view columns (Fujii Masao)

Renaming view columns was already possible, but one had to write `ALTER TABLE RENAME COLUMN`, which is confusing.

- Add `ALTER TYPE` options to modify a base type's `TOAST` properties and support functions (Tomas Vondra, Tom Lane)

- Add `CREATE DATABASE LOCALE` option (Peter Eisentraut)

This combines the existing options `LC_COLLATE` and `LC_CTYPE` into a single option.

- Allow `DROP DATABASE` to disconnect sessions using the target database, allowing the drop to succeed (Pavel Stehule, Amit Kapila)

This is enabled by the `FORCE` option.

- Add structure member `tg_updatedcols` to allow C-language update triggers to know which column(s) were updated (Peter Eisentraut)

#### E.17.3.4. Data Types

- Add polymorphic data types for use by functions requiring compatible arguments (Pavel Stehule)

The new data types are `anycompatible`, `anycompatiblearray`, `anycompatiblenonarray`, and `anycompatiblerange`.

- Add SQL data type `xid8` to expose `FullTransactionId` (Thomas Munro)

The existing `xid` data type is only four bytes so it does not provide the transaction epoch.

- Add data type `regcollation` and associated functions, to represent OIDs of collation objects (Julien Rouhaud)
- Use the `glibc` version in some cases as a `collation` version identifier (Thomas Munro)

If the `glibc` version changes, a warning will be issued about possible corruption of collation-dependent indexes.

- Add support for collation versions on Windows (Thomas Munro)
- Allow `ROW expressions` to have their members extracted with suffix notation (Tom Lane)

For example, `(ROW(4, 5.0)).f1` now returns 4.

#### E.17.3.5. Functions

- Add alternate version of `jsonb_set()` with improved `NULL` handling (Andrew Dunstan)

The new function, `jsonb_set_lax()`, handles a `NULL` new value by either setting the specified key to a JSON null, deleting the key, raising an exception, or returning the `jsonb` value unmodified, as requested.

- Add `jsonpath.datetime()` method (Nikita Glukhov, Teodor Sigaev, Oleg Bartunov, Alexander Korotkov)

This function allows JSON values to be converted to timestamps, which can then be processed in `jsonpath` expressions. This change also adds `jsonpath` functions that support time-zone-aware output.

- Add SQL functions `NORMALIZE()` to normalize Unicode strings, and `IS NORMALIZED` to check for normalization (Peter Eisentraut)
- Add `min()` and `max()` aggregates for `pg_lsn` (Fabrício de Royes Mello)

These are particularly useful in monitoring queries.

- Allow `Unicode escapes`, e.g., `E'\unnnn'` or `U'\nnnn'`, to specify any character available in the database encoding, even when the database encoding is not UTF-8 (Tom Lane)
- Allow `to_date()` and `to_timestamp()` to recognize non-English month/day names (Juan José Santamaría Flecha, Tom Lane)

The names recognized are the same as those output by `to_char()` with the same format patterns.

- Add datetime format patterns `FF1 - FF6` to specify input or output of 1 to 6 fractional-second digits (Alexander Korotkov, Nikita Glukhov, Teodor Sigaev, Oleg Bartunov)

These patterns can be used by `to_char()`, `to_timestamp()`, and `jsonpath's .datetime()`.

- Add `SSSSS` datetime format pattern as an SQL-standard alias for `SSSS` (Nikita Glukhov, Alexander Korotkov)
- Add function `gen_random_uuid()` to generate version-4 UUIDs (Peter Eisentraut)
- Previously UUID generation functions were only available in the external modules `uuid-oss` and `pgcrypto`.
- Add greatest-common-denominator (`gcd`) and least-common-multiple (`lcm`) functions (Vik Fearing)
- Improve the performance and accuracy of the `numeric` type's `square root` (`sqrt`) and natural log (`ln`) functions (Dean Rasheed)
- Add function `min_scale()` that returns the number of digits to the right of the decimal point that are required to represent a `numeric` value with full accuracy (Pavel Stehule)
- Add function `trim_scale()` to reduce the scale of a `numeric` value by removing trailing zeros (Pavel Stehule)
- Add commutators of `distance operators` (Nikita Glukhov)

For example, previously only `point <-> line` was supported, now `line <-> point` works too.

- Create `xid8` versions of all `transaction ID functions` (Thomas Munro)

The old `xid`-based functions still exist, for backward compatibility.

- Allow `get_bit()` and `set_bit()` to set bits beyond the first 256MB of a `bytea` value (Movead Li)
- Allow `advisory-lock functions` to be used in some parallel operations (Tom Lane)
- Add the ability to remove an object's dependency on an extension (Álvaro Herrera)

The object can be a function, materialized view, index, or trigger. The syntax is `ALTER .. NO DEPENDS ON`.

### E.17.3.6. PL/pgSQL

- Improve performance of simple PL/pgSQL expressions (Tom Lane, Amit Langote)
- Improve performance of PL/pgSQL functions that use immutable expressions (Konstantin Knizhnik)

### E.17.3.7. Client Interfaces

- Allow `libpq` clients to require channel binding for encrypted connections (Jeff Davis)

Using the `libpq` connection parameter `channel_binding` forces the other end of the TLS connection to prove it knows the user's password. This prevents man-in-the-middle attacks.

- Add `libpq` connection parameters to control the minimum and maximum TLS version allowed for an encrypted connection (Daniel Gustafsson)

The settings are `ssl_min_protocol_version` and `ssl_max_protocol_version`. By default, the minimum TLS version is 1.2 (this represents a behavioral change from previous releases).

- Allow use of passwords to unlock client certificates (Craig Ringer, Andrew Dunstan)

This is enabled by `libpq's sslpassword` connection parameter.

- Allow `libpq` to use DER-encoded client certificates (Craig Ringer, Andrew Dunstan)
- Fix `ecpg's EXEC SQL elif` directive to work correctly (Tom Lane)

Previously it behaved the same as `endif` followed by `ifdef`, so that a successful previous branch of the same `if` construct did not prevent expansion of the `elif` branch or following branches.

### E.17.3.8. Client Applications

- Add transaction status (`%x`) to `psql`'s default [prompts](#) (Vik Fearing)
- Allow the secondary `psql` prompt to be blank but the same width as the primary prompt (Thomas Munro)

This is accomplished by setting `PROMPT2` to `%w`.

- Allow `psql`'s `\g` and `\gx` commands to change [\pset](#) output options for the duration of that single command (Tom Lane)

This feature allows syntax like `\g (expand=on)`, which is equivalent to `\gx`.

- Add `psql` commands to display operator classes and operator families (Sergey Cherkashin, Nikita Glukhov, Alexander Korotkov)

The new commands are `\dAc`, `\dAf`, `\dAo`, and `\dAp`.

- Show table persistence in `psql`'s `\dt+` and related commands (David Fetter)

In verbose mode, the table/index/view shows if the object is permanent, temporary, or unlogged.

- Improve output of `psql`'s `\d` for TOAST tables (Justin Pryzby)
- Fix redisplay after `psql`'s `\e` command (Tom Lane)

When exiting the editor, if the query doesn't end with a semicolon or `\g`, the query buffer contents will now be displayed.

- Add `\warn` command to `psql` (David Fetter)

This is like `\echo` except that the text is sent to `stderr` instead of `stdout`.

- Add the PostgreSQL home page to command-line `--help` output (Peter Eisentraut)

#### E.17.3.8.2. [pgbench](#)

- Allow `pgbench` to partition its “accounts” table (Fabien Coelho)

This allows performance testing of partitioning.

- Add `pgbench` command `\aset`, which behaves like `\gset`, but for multiple queries (Fabien Coelho)
- Allow `pgbench` to generate its initial data server-side, rather than client-side (Fabien Coelho)
- Allow `pgbench` to show script contents using option `--show-script` (Fabien Coelho)

### E.17.3.9. Server Applications

- Generate backup manifests for base backups, and verify them (Robert Haas)

A new tool [pg\\_verifybackup](#) can verify backups.

- Have [pg\\_basebackup](#) estimate the total backup size by default (Fujii Masao)

This computation allows [pg\\_stat\\_progress\\_basebackup](#) to show progress. If that is not needed, it can be disabled by using the `--no-estimate-size` option. Previously, this computation happened only if the `--progress` option was used.

- Add an option to [pg\\_rewind](#) to configure standbys (Paul Guo, Jimmy Yih, Ashwin Agrawal)

This matches [pg\\_basebackup](#)'s `--write-recovery-conf` option.

- Allow `pg_rewind` to use the target cluster's `restore_command` to retrieve needed WAL (Alexey Kondratov)

This is enabled using the `-c/--restore-target-wal` option.

- Have `pg_rewind` automatically run crash recovery before rewinding (Paul Guo, Jimmy Yih, Ashwin Agrawal)

This can be disabled by using `--no-ensure-shutdown`.

- Increase the `PREPARE TRANSACTION`-related information reported by `pg_waldump` (Fujii Masao)
- Add `pg_waldump` option `--quiet` to suppress non-error output (Andres Freund, Robert Haas)
- Add `pg_dump` option `--include-foreign-data` to dump data from foreign servers (Luis Carril)
- Allow vacuum commands run by `vacuumdb` to operate in parallel mode (Masahiko Sawada)

This is enabled with the new `--parallel` option.

- Allow `reindexdb` to operate in parallel (Julien Rouhaud)

Parallel mode is enabled with the new `--jobs` option.

- Allow `dropdb` to disconnect sessions using the target database, allowing the drop to succeed (Pavel Stehule)

This is enabled with the `-f` option.

- Remove `--adduser` and `--no-adduser` from `createuser` (Alexander Lakhin)

The long-supported preferred options for this are called `--superuser` and `--no-superuser`.

- Use the directory of the `pg_upgrade` program as the default `--new-bindir` setting when running `pg_upgrade` (Daniel Gustafsson)

### E.17.3.10. Documentation

- Add a `glossary` to the documentation (Corey Huinker, Jürgen Purtz, Roger Harkavy, Álvaro Herrera)
- Reformat tables containing `function and operator information` for better clarity (Tom Lane)
- Upgrade to use DocBook 4.5 (Peter Eisentraut)

### E.17.3.11. Source Code

- Add support for building on Visual Studio 2019 (Haribabu Kommi)
- Add build support for MSYS2 (Peter Eisentraut)
- Add `compare_exchange` and `fetch_add` assembly language code for Power PC compilers (Noah Misch)
- Update `Snowball stemmer` dictionaries used by full text search (Panagiotis Mavrogiorgos)

This adds Greek stemming and improves Danish and French stemming.

- Remove support for Windows 2000 (Michael Paquier)
- Remove support for non-ELF BSD systems (Peter Eisentraut)
- Remove `support` for Python versions 2.5.X and earlier (Peter Eisentraut)
- Remove support for OpenSSL 0.9.8 and 1.0.0 (Michael Paquier)
- Remove configure options `--disable-float8-byval` and `--disable-float4-byval` (Peter Eisentraut)

These were needed for compatibility with some version-zero C functions, but those are no longer supported.

- Pass the query string to planner hook functions (Pascal Legrand, Julien Rouhaud)

- Add `TRUNCATE` command hook (Yuli Khodorkovskiy)
- Add TLS init hook (Andrew Dunstan)
- Allow building with no predefined Unix-domain socket directory (Peter Eisentraut)
- Reduce the probability of SysV resource key collision on Unix platforms (Tom Lane)
- Use operating system functions to reliably erase memory that contains sensitive information (Peter Eisentraut)

For example, this is used for clearing passwords stored in memory.

- Add `headerscheck` script to test C header-file compatibility (Tom Lane)
- Implement internal lists as arrays, rather than a chain of cells (Tom Lane)

This improves performance for queries that access many objects.

- Change the API for `TS_execute()` (Tom Lane, Pavel Borisov)

`TS_execute` callbacks must now provide ternary (yes/no/maybe) logic. Calculating NOT queries accurately is now the default.

### E.17.3.12. Additional Modules

- Allow `extensions` to be specified as trusted (Tom Lane)

Such extensions can be installed in a database by users with database-level `CREATE` privileges, even if they are not superusers. This change also removes the `pg_pltemplate` system catalog.

- Allow non-superusers to connect to `postgres_fdw` foreign servers without using a password (Craig Ringer)

Specifically, allow a superuser to set `password_required` to false for a `user mapping`. Care must still be taken to prevent non-superusers from using superuser credentials to connect to the foreign server.

- Allow `postgres_fdw` to use certificate authentication (Craig Ringer)

Different users can use different certificates.

- Allow `sepgsql` to control access to the `TRUNCATE` command (Yuli Khodorkovskiy)
- Add extension `bool_plperl` which transforms SQL booleans to/from PL/Perl booleans (Ivan Panchenko)
- Have `pg_stat_statements` treat `SELECT ... FOR UPDATE` commands as distinct from those without `FOR UPDATE` (Andrew Gierth, Vik Fearing)
- Allow `pg_stat_statements` to optionally track the planning time of statements (Julien Rouhaud, Pascal Legrand, Thomas Munro, Fujii Masao)

Previously only execution time was tracked.

- Overhaul `ltree`'s lquery syntax to treat NOT (!) more logically (Filip Rembalkowski, Tom Lane, Nikita Glukhov)

Also allow non-\* queries to use a numeric range ({} ) of matches.

- Add support for binary I/O of `ltree`, `lquery`, and `ltxquery` types (Nino Floris)
- Add an option to `dict_int` to ignore the sign of integers (Jeff Janes)
- Add `adminpack` function `pg_file_sync()` to allow fsync'ing a file (Fujii Masao)
- Add `pageinspect` functions to output `t_infomask/t_infomask2` values in human-readable format (Craig Ringer, Sawada Masahiko, Michael Paquier)
- Add B-tree index de-duplication processing columns to `pageinspect` output (Peter Geoghegan)

## E.17.4. Acknowledgments

The following individuals (in alphabetical order) have contributed to this release as patch authors, committers, reviewers, testers, or reporters of issues.

## E.18. Prior Releases

Release notes for prior versions can be found online. At the time of Postgres Pro Standard 13 release, these prior versions were supported:

- Postgres Pro Standard 12: <https://postgrespro.com/docs/postgrespro/12/release.html>
- Postgres Pro Standard 11: <https://postgrespro.com/docs/postgrespro/11/release.html>
- Postgres Pro Standard 10: <https://postgrespro.com/docs/postgrespro/10/release.html>
- Postgres Pro Standard 9.6: <https://postgrespro.com/docs/postgrespro/9.6/release.html>
- Postgres Pro Standard 9.5: <https://postgrespro.com/docs/postgrespro/9.5/release.html>

---

# Appendix F. Additional Supplied Modules

This appendix and the next one contain information regarding additional modules available in the Postgres Pro Standard distribution. These include porting tools, analysis utilities, and plug-in features that are not part of the core Postgres Pro system, mainly because they address a limited audience or are too experimental to be part of the main source tree. This does not preclude their usefulness.

This appendix covers the extensions and other server plug-in modules. [Appendix G](#) covers the utility programs.

In Postgres Pro Standard, these modules are made available as a separate subpackage `postgrespro-std-13-contrib`.

Many modules supply new user-defined functions, operators, or types. To make use of one of these modules, after you have installed the code you need to register the new SQL objects in the database system. This is done by executing a [CREATE EXTENSION](#) command. In a fresh database, you can simply do

```
CREATE EXTENSION module_name;
```

This command registers the new SQL objects in the current database only, so you need to run it in each database that you want the module's facilities to be available in. Alternatively, run it in database `template1` so that the extension will be copied into subsequently-created databases by default.

For all these modules, `CREATE EXTENSION` must be run by a database superuser, unless the module is considered “trusted”, in which case it can be run by any user who has `CREATE` privilege on the current database. Modules that are trusted are identified as such in the sections that follow. Generally, trusted modules are ones that cannot provide access to outside-the-database functionality.

Many modules allow you to install their objects in a schema of your choice. To do that, add `SCHEMA schema_name` to the `CREATE EXTENSION` command. By default, the objects will be placed in your current creation target schema, which in turn defaults to `public`.

Note, however, that some of these modules are not “extensions” in this sense, but are loaded into the server in some other way, for instance by way of [shared\\_preload\\_libraries](#). See the documentation of each module for details.

## F.1. adminpack

`adminpack` provides a number of support functions which pgAdmin and other administration and management tools can use to provide additional functionality, such as remote management of server log files. Use of all these functions is only allowed to the superuser by default but may be allowed to other users by using the `GRANT` command.

The functions shown in [Table F.1](#) provide write access to files on the machine hosting the server. (See also the functions in [Table 9.95](#), which provide read-only access.) Only files within the database cluster directory can be accessed, unless the user is a superuser or given one of the `pg_read_server_files`, or `pg_write_server_files` roles, as appropriate for the function, but either a relative or absolute path is allowable.

**Table F.1. adminpack Functions**

Function	Description
<code>pg_catalog.pg_file_write</code>	<code>( filename text, data text, append boolean ) → bigint</code> Writes, or appends to, a text file.
<code>pg_catalog.pg_file_sync</code>	<code>( filename text ) → void</code>

Function	Description
	Flushes a file or directory to disk.
<code>pg_catalog.pg_file_rename</code>	( <i>oldname</i> text, <i>newname</i> text [, <i>archivename</i> text ] ) → boolean Renames a file.
<code>pg_catalog.pg_file_unlink</code>	( <i>filename</i> text ) → boolean Removes a file.
<code>pg_catalog.pg_logdir_ls</code>	( ) → setof record Lists the log files in the <code>log_directory</code> directory.

`pg_file_write` writes the specified *data* into the file named by *filename*. If *append* is false, the file must not already exist. If *append* is true, the file can already exist, and will be appended to if so. Returns the number of bytes written.

`pg_file_sync` fsyncs the specified file or directory named by *filename*. An error is thrown on failure (e.g., the specified file is not present). Note that `data_sync_retry` has no effect on this function, and therefore a PANIC-level error will not be raised even on failure to flush database files.

`pg_file_rename` renames a file. If *archivename* is omitted or NULL, it simply renames *oldname* to *newname* (which must not already exist). If *archivename* is provided, it first renames *newname* to *archivename* (which must not already exist), and then renames *oldname* to *newname*. In event of failure of the second rename step, it will try to rename *archivename* back to *newname* before reporting the error. Returns true on success, false if the source file(s) are not present or not writable; other cases throw errors.

`pg_file_unlink` removes the specified file. Returns true on success, false if the specified file is not present or the `unlink()` call fails; other cases throw errors.

`pg_logdir_ls` returns the start timestamps and path names of all the log files in the `log_directory` directory. The `log_filename` parameter must have its default setting (`postgresql-%Y-%m-%d_%H%M%S.log`) to use this function.

## F.2. amcheck

The `amcheck` module provides functions that allow you to verify the logical consistency of the structure of relations. If the structure appears to be valid, no error is raised.

The functions verify various *invariants* in the structure of the representation of particular relations. The correctness of the access method functions behind index scans and other important operations relies on these invariants always holding. For example, certain functions verify, among other things, that all B-Tree pages have items in “logical” order (e.g., for B-Tree indexes on `text`, index tuples should be in collated lexical order). If that particular invariant somehow fails to hold, we can expect binary searches on the affected page to incorrectly guide index scans, resulting in wrong answers to SQL queries.

Verification is performed using the same procedures as those used by index scans themselves, which may be user-defined operator class code. For example, B-Tree index verification relies on comparisons made with one or more B-Tree support function 1 routines. See [Section 35.16.3](#) for details of operator class support functions.

`amcheck` functions may only be used by superusers.

### F.2.1. Functions

`bt_index_check(index regclass, heapallindexed boolean)` returns void

`bt_index_check` tests that its target, a B-Tree index, respects a variety of invariants. Example usage:

```

test=# SELECT bt_index_check(index => c.oid, heapallindexed => i.indisunique),
           c.relname,
           c.relpages
FROM pg_index i
JOIN pg_opclass op ON i.indclass[0] = op.oid
JOIN pg_am am ON op.opcmethod = am.oid
JOIN pg_class c ON i.indexrelid = c.oid
JOIN pg_namespace n ON c.relnamespace = n.oid
WHERE am.amname = 'btree' AND n.nspname = 'pg_catalog'
-- Don't check temp tables, which may be from another session:
AND c.relpersistence != 't'
-- Function may throw an error when this is omitted:
AND c.relkind = 'i' AND i.indisready AND i.indisvalid
ORDER BY c.relpages DESC LIMIT 10;
  bt_index_check |                relname                | relpages
-----+-----+-----
          | pg_depend_reference_index              |        43
          | pg_depend_depender_index               |        40
          | pg_proc_proname_args_nsp_index         |        31
          | pg_description_o_c_o_index             |        21
          | pg_attribute_relid_attnam_index        |        14
          | pg_proc_oid_index                      |        10
          | pg_attribute_relid_attnum_index         |         9
          | pg_amproc_fam_proc_index               |         5
          | pg_amop_opr_fam_index                  |         5
          | pg_amop_fam_strat_index                 |         5
(10 rows)

```

This example shows a session that performs verification of the 10 largest catalog indexes in the database “test”. Verification of the presence of heap tuples as index tuples is requested for the subset that are unique indexes. Since no error is raised, all indexes tested appear to be logically consistent. Naturally, this query could easily be changed to call `bt_index_check` for every index in the database where verification is supported.

`bt_index_check` acquires an `AccessShareLock` on the target index and the heap relation it belongs to. This lock mode is the same lock mode acquired on relations by simple `SELECT` statements. `bt_index_check` does not verify invariants that span child/parent relationships, but will verify the presence of all heap tuples as index tuples within the index when `heapallindexed` is `true`. When a routine, lightweight test for corruption is required in a live production environment, using `bt_index_check` often provides the best trade-off between thoroughness of verification and limiting the impact on application performance and availability.

`bt_index_parent_check(index regclass, heapallindexed boolean, rootdescend boolean)`  
returns void

`bt_index_parent_check` tests that its target, a B-Tree index, respects a variety of invariants. Optionally, when the `heapallindexed` argument is `true`, the function verifies the presence of all heap tuples that should be found within the index. When the optional `rootdescend` argument is `true`, verification re-finds tuples on the leaf level by performing a new search from the root page for each tuple. The checks that can be performed by `bt_index_parent_check` are a superset of the checks that can be performed by `bt_index_check`. `bt_index_parent_check` can be thought of as a more thorough variant of `bt_index_check`: unlike `bt_index_check`, `bt_index_parent_check` also checks invariants that span parent/child relationships, including checking that there are no missing downlinks in the index structure. `bt_index_parent_check` follows the general convention of raising an error if it finds a logical inconsistency or other problem.

A `ShareLock` is required on the target index by `bt_index_parent_check` (a `ShareLock` is also acquired on the heap relation). These locks prevent concurrent data modification from `INSERT`, `UPDATE`, and `DELETE` commands. The locks also prevent the underlying relation from being concurrently processed

by `VACUUM`, as well as all other utility commands. Note that the function holds locks only while running, not for the entire transaction.

`bt_index_parent_check`'s additional verification is more likely to detect various pathological cases. These cases may involve an incorrectly implemented B-Tree operator class used by the index that is checked, or, hypothetically, undiscovered bugs in the underlying B-Tree index access method code. Note that `bt_index_parent_check` cannot be used when Hot Standby mode is enabled (i.e., on read-only physical replicas), unlike `bt_index_check`.

### Tip

`bt_index_check` and `bt_index_parent_check` both output log messages about the verification process at `DEBUG1` and `DEBUG2` severity levels. These messages provide detailed information about the verification process that may be of interest to PostgreSQL developers. Advanced users may also find this information helpful, since it provides additional context should verification actually detect an inconsistency. Running:

```
SET client_min_messages = DEBUG1;
```

in an interactive `psql` session before running a verification query will display messages about the progress of verification with a manageable level of detail.

## F.2.2. Optional *heapallindexed* Verification

When the *heapallindexed* argument to verification functions is `true`, an additional phase of verification is performed against the table associated with the target index relation. This consists of a “dummy” `CREATE INDEX` operation, which checks for the presence of all hypothetical new index tuples against a temporary, in-memory summarizing structure (this is built when needed during the basic first phase of verification). The summarizing structure “fingerprints” every tuple found within the target index. The high level principle behind *heapallindexed* verification is that a new index that is equivalent to the existing, target index must only have entries that can be found in the existing structure.

The additional *heapallindexed* phase adds significant overhead: verification will typically take several times longer. However, there is no change to the relation-level locks acquired when *heapallindexed* verification is performed.

The summarizing structure is bound in size by `maintenance_work_mem`. In order to ensure that there is no more than a 2% probability of failure to detect an inconsistency for each heap tuple that should be represented in the index, approximately 2 bytes of memory are needed per tuple. As less memory is made available per tuple, the probability of missing an inconsistency slowly increases. This approach limits the overhead of verification significantly, while only slightly reducing the probability of detecting a problem, especially for installations where verification is treated as a routine maintenance task. Any single absent or malformed tuple has a new opportunity to be detected with each new verification attempt.

## F.2.3. Using `amcheck` Effectively

`amcheck` can be effective at detecting various types of failure modes that [data page checksums](#) will always fail to catch. These include:

- Structural inconsistencies caused by incorrect operator class implementations.

This includes issues caused by the comparison rules of operating system collations changing. Comparisons of datums of a collatable type like `text` must be immutable (just as all comparisons used for B-Tree index scans must be immutable), which implies that operating system collation rules must never change. Though rare, updates to operating system collation rules can cause these issues. More commonly, an inconsistency in the collation order between a master server and a standby server is implicated, possibly because the *major* operating system version in use is

inconsistent. Such inconsistencies will generally only arise on standby servers, and so can generally only be detected on standby servers.

If a problem like this arises, it may not affect each individual index that is ordered using an affected collation, simply because *indexed* values might happen to have the same absolute ordering regardless of the behavioral inconsistency. See [Section 22.1](#) and [Section 22.2](#) for further details about how Postgres Pro uses operating system locales and collations.

- Structural inconsistencies between indexes and the heap relations that are indexed (when *heapallindexed* verification is performed).

There is no cross-checking of indexes against their heap relation during normal operation. Symptoms of heap corruption can be subtle.

- Corruption caused by hypothetical undiscovered bugs in the underlying Postgres Pro access method code, sort code, or transaction management code.

Automatic verification of the structural integrity of indexes plays a role in the general testing of new or proposed Postgres Pro features that could plausibly allow a logical inconsistency to be introduced. Verification of table structure and associated visibility and transaction status information plays a similar role. One obvious testing strategy is to call `amcheck` functions continuously when running the standard regression tests.

- File system or storage subsystem faults where checksums happen to simply not be enabled.

Note that `amcheck` examines a page as represented in some shared memory buffer at the time of verification if there is only a shared buffer hit when accessing the block. Consequently, `amcheck` does not necessarily examine data read from the file system at the time of verification. Note that when checksums are enabled, `amcheck` may raise an error due to a checksum failure when a corrupt block is read into a buffer.

- Corruption caused by faulty RAM, or the broader memory subsystem.

Postgres Pro does not protect against correctable memory errors and it is assumed you will operate using RAM that uses industry standard Error Correcting Codes (ECC) or better protection. However, ECC memory is typically only immune to single-bit errors, and should not be assumed to provide *absolute* protection against failures that result in memory corruption.

When *heapallindexed* verification is performed, there is generally a greatly increased chance of detecting single-bit errors, since strict binary equality is tested, and the indexed attributes within the heap are tested.

In general, `amcheck` can only prove the presence of corruption; it cannot prove its absence.

## F.2.4. Repairing Corruption

No error concerning corruption raised by `amcheck` should ever be a false positive. `amcheck` raises errors in the event of conditions that, by definition, should never happen, and so careful analysis of `amcheck` errors is often required.

There is no general method of repairing problems that `amcheck` detects. An explanation for the root cause of an invariant violation should be sought. `pageinspect` may play a useful role in diagnosing corruption that `amcheck` detects. A `REINDEX` may not be effective in repairing corruption.

## F.3. `auth_delay`

`auth_delay` causes the server to pause briefly before reporting authentication failure, to make brute-force attacks on database passwords more difficult. Note that it does nothing to prevent denial-of-service attacks, and may even exacerbate them, since processes that are waiting before reporting authentication failure will still consume connection slots.

In order to function, this module must be loaded via [shared\\_preload\\_libraries](#) in `postgresql.conf`.

### F.3.1. Configuration Parameters

`auth_delay.milliseconds` (int)

The number of milliseconds to wait before reporting an authentication failure. The default is 0.

These parameters must be set in `postgresql.conf`. Typical usage might be:

```
# postgresql.conf
shared_preload_libraries = 'auth_delay'

auth_delay.milliseconds = '500'
```

### F.3.2. Author

KaiGai Kohei <kaigai@ak.jp.nec.com>

## F.4. auto\_explain

The `auto_explain` module provides a means for logging execution plans of slow statements automatically, without having to run `EXPLAIN` by hand. This is especially helpful for tracking down unoptimized queries in large applications.

The module provides no SQL-accessible functions. To use it, simply load it into the server. You can load it into an individual session:

```
LOAD 'auto_explain';
```

(You must be superuser to do that.) More typical usage is to preload it into some or all sessions by including `auto_explain` in `session_preload_libraries` or `shared_preload_libraries` in `postgresql.conf`. Then you can track unexpectedly slow queries no matter when they happen. Of course there is a price in overhead for that.

### F.4.1. Configuration Parameters

There are several configuration parameters that control the behavior of `auto_explain`. Note that the default behavior is to do nothing, so you must set at least `auto_explain.log_min_duration` if you want any results.

`auto_explain.log_min_duration` (integer)

`auto_explain.log_min_duration` is the minimum statement execution time, in milliseconds, that will cause the statement's plan to be logged. Setting this to 0 logs all plans. -1 (the default) disables logging of plans. For example, if you set it to 250ms then all statements that run 250ms or longer will be logged. Only superusers can change this setting.

`auto_explain.log_analyze` (boolean)

`auto_explain.log_analyze` causes `EXPLAIN ANALYZE` output, rather than just `EXPLAIN` output, to be printed when an execution plan is logged. This parameter is off by default. Only superusers can change this setting.

#### Note

When this parameter is on, per-plan-node timing occurs for all statements executed, whether or not they run long enough to actually get logged. This can have an extremely negative impact on performance. Turning off `auto_explain.log_timing` ameliorates the performance cost, at the price of obtaining less information.

`auto_explain.log_buffers` (boolean)

`auto_explain.log_buffers` controls whether buffer usage statistics are printed when an execution plan is logged; it's equivalent to the `BUFFERS` option of `EXPLAIN`. This parameter has no effect unless `auto_explain.log_analyze` is enabled. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_wal` (boolean)

`auto_explain.log_wal` controls whether WAL usage statistics are printed when an execution plan is logged; it's equivalent to the `WAL` option of `EXPLAIN`. This parameter has no effect unless `auto_explain.log_analyze` is enabled. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_timing` (boolean)

`auto_explain.log_timing` controls whether per-node timing information is printed when an execution plan is logged; it's equivalent to the `TIMING` option of `EXPLAIN`. The overhead of repeatedly reading the system clock can slow down queries significantly on some systems, so it may be useful to set this parameter to off when only actual row counts, and not exact times, are needed. This parameter has no effect unless `auto_explain.log_analyze` is enabled. This parameter is on by default. Only superusers can change this setting.

`auto_explain.log_triggers` (boolean)

`auto_explain.log_triggers` causes trigger execution statistics to be included when an execution plan is logged. This parameter has no effect unless `auto_explain.log_analyze` is enabled. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_verbose` (boolean)

`auto_explain.log_verbose` controls whether verbose details are printed when an execution plan is logged; it's equivalent to the `VERBOSE` option of `EXPLAIN`. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_settings` (boolean)

`auto_explain.log_settings` controls whether information about modified configuration options is printed when an execution plan is logged. Only options affecting query planning with value different from the built-in default value are included in the output. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_format` (enum)

`auto_explain.log_format` selects the `EXPLAIN` output format to be used. The allowed values are `text`, `xml`, `json`, and `yaml`. The default is `text`. Only superusers can change this setting.

`auto_explain.log_level` (enum)

`auto_explain.log_level` selects the log level at which `auto_explain` will log the query plan. Valid values are `DEBUG5`, `DEBUG4`, `DEBUG3`, `DEBUG2`, `DEBUG1`, `INFO`, `NOTICE`, `WARNING`, and `LOG`. The default is `LOG`. Only superusers can change this setting.

`auto_explain.log_nested_statements` (boolean)

`auto_explain.log_nested_statements` causes nested statements (statements executed inside a function) to be considered for logging. When it is off, only top-level query plans are logged. This parameter is off by default. Only superusers can change this setting.

`auto_explain.sample_rate` (real)

`auto_explain.sample_rate` causes `auto_explain` to only explain a fraction of the statements in each session. The default is 1, meaning explain all the queries. In case of nested statements, either all will be explained or none. Only superusers can change this setting.

In ordinary usage, these parameters are set in `postgresql.conf`, although superusers can alter them on-the-fly within their own sessions. Typical usage might be:

```
# postgresql.conf
session_preload_libraries = 'auto_explain'

auto_explain.log_min_duration = '3s'
```

## F.4.2. Example

```
postgres=# LOAD 'auto_explain';
postgres=# SET auto_explain.log_min_duration = 0;
postgres=# SET auto_explain.log_analyze = true;
postgres=# SELECT count(*)
           FROM pg_class, pg_index
           WHERE oid = indrelid AND indisunique;
```

This might produce log output such as:

```
LOG:  duration: 0.196 ms planning: 0.548 ms plan:
       Query Text: SELECT count(*)
                   FROM pg_class, pg_index
                   WHERE oid = indrelid AND indisunique;
       Aggregate  (cost=16.79..16.80 rows=1 width=0) (actual time=3.626..3.627 rows=1
loops=1)
       -> Hash Join  (cost=4.17..16.55 rows=92 width=0) (actual time=3.349..3.594 rows=92
loops=1)
           Hash Cond: (pg_class.oid = pg_index.indrelid)
           -> Seq Scan on pg_class  (cost=0.00..9.55 rows=255 width=4) (actual
time=0.016..0.140 rows=255 loops=1)
           -> Hash  (cost=3.02..3.02 rows=92 width=4) (actual time=3.238..3.238 rows=92
loops=1)
               Buckets: 1024  Batches: 1  Memory Usage: 4kB
               -> Seq Scan on pg_index  (cost=0.00..3.02 rows=92 width=4) (actual
time=0.008..3.187 rows=92 loops=1)
                   Filter: indisunique
```

Note that Postgres Pro added a new field to the output to show planning time.

## F.5. bloom

`bloom` provides an index access method based on *Bloom filters*.

A Bloom filter is a space-efficient data structure that is used to test whether an element is a member of a set. In the case of an index access method, it allows fast exclusion of non-matching tuples via signatures whose size is determined at index creation.

A signature is a lossy representation of the indexed attribute(s), and as such is prone to reporting false positives; that is, it may be reported that an element is in the set, when it is not. So index search results must always be rechecked using the actual attribute values from the heap entry. Larger signatures reduce the odds of a false positive and thus reduce the number of useless heap visits, but of course also make the index larger and hence slower to scan.

This type of index is most useful when a table has many attributes and queries test arbitrary combinations of them. A traditional btree index is faster than a bloom index, but it can require many btree indexes to

support all possible queries where one needs only a single bloom index. Note however that bloom indexes only support equality queries, whereas btree indexes can also perform inequality and range searches.

### F.5.1. Parameters

A bloom index accepts the following parameters in its `WITH` clause:

`length`

Length of each signature (index entry) in bits. It is rounded up to the nearest multiple of 16. The default is 80 bits and the maximum is 4096.

`col1 - col32`

Number of bits generated for each index column. Each parameter's name refers to the number of the index column that it controls. The default is 2 bits and the maximum is 4095. Parameters for index columns not actually used are ignored.

### F.5.2. Examples

This is an example of creating a bloom index:

```
CREATE INDEX bloomidx ON tbloom USING bloom (i1,i2,i3)
  WITH (length=80, col1=2, col2=2, col3=4);
```

The index is created with a signature length of 80 bits, with attributes `i1` and `i2` mapped to 2 bits, and attribute `i3` mapped to 4 bits. We could have omitted the `length`, `col1`, and `col2` specifications since those have the default values.

Here is a more complete example of bloom index definition and usage, as well as a comparison with equivalent btree indexes. The bloom index is considerably smaller than the btree index, and can perform better.

```
=# CREATE TABLE tbloom AS
  SELECT
    (random() * 1000000)::int as i1,
    (random() * 1000000)::int as i2,
    (random() * 1000000)::int as i3,
    (random() * 1000000)::int as i4,
    (random() * 1000000)::int as i5,
    (random() * 1000000)::int as i6
  FROM
    generate_series(1,10000000);
SELECT 10000000
```

A sequential scan over this large table takes a long time:

```
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
      QUERY PLAN
```

```
-----
Seq Scan on tbloom (cost=0.00..2137.14 rows=3 width=24) (actual time=15.480..15.480
rows=0 loops=1)
  Filter: ((i2 = 898732) AND (i5 = 123451))
  Rows Removed by Filter: 100000
Planning Time: 0.340 ms
Execution Time: 15.501 ms
(5 rows)
```

Even with the btree index defined the result will still be a sequential scan:

```
=# CREATE INDEX btreeidx ON tbloom (i1, i2, i3, i4, i5, i6);
```

```

CREATE INDEX
=# SELECT pg_size_pretty(pg_relation_size('btreeidx'));
pg_size_pretty
-----
3976 kB
(1 row)
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
QUERY PLAN
-----
Seq Scan on tbloom (cost=0.00..2137.00 rows=2 width=24) (actual time=12.604..12.604
rows=0 loops=1)
  Filter: ((i2 = 898732) AND (i5 = 123451))
  Rows Removed by Filter: 100000
Planning Time: 0.155 ms
Execution Time: 12.617 ms
(5 rows)

```

Having the bloom index defined on the table is better than btree in handling this type of search:

```

=# CREATE INDEX bloomidx ON tbloom USING bloom (i1, i2, i3, i4, i5, i6);
CREATE INDEX
=# SELECT pg_size_pretty(pg_relation_size('bloomidx'));
pg_size_pretty
-----
1584 kB
(1 row)
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
QUERY PLAN
-----
Bitmap Heap Scan on tbloom (cost=1792.00..1799.69 rows=2 width=24) (actual
time=0.384..0.384 rows=0 loops=1)
  Recheck Cond: ((i2 = 898732) AND (i5 = 123451))
  Rows Removed by Index Recheck: 26
  Heap Blocks: exact=26
-> Bitmap Index Scan on bloomidx (cost=0.00..1792.00 rows=2 width=0) (actual
time=0.350..0.350 rows=26 loops=1)
  Index Cond: ((i2 = 898732) AND (i5 = 123451))
Planning Time: 0.122 ms
Execution Time: 0.407 ms
(8 rows)

```

Now, the main problem with the btree search is that btree is inefficient when the search conditions do not constrain the leading index column(s). A better strategy for btree is to create a separate index on each column. Then the planner will choose something like this:

```

=# CREATE INDEX btreeidx1 ON tbloom (i1);
CREATE INDEX
=# CREATE INDEX btreeidx2 ON tbloom (i2);
CREATE INDEX
=# CREATE INDEX btreeidx3 ON tbloom (i3);
CREATE INDEX
=# CREATE INDEX btreeidx4 ON tbloom (i4);
CREATE INDEX
=# CREATE INDEX btreeidx5 ON tbloom (i5);
CREATE INDEX

```

```

=# CREATE INDEX btreeidx6 ON tbloom (i6);
CREATE INDEX
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
                                QUERY PLAN

-----
Bitmap Heap Scan on tbloom  (cost=24.34..32.03 rows=2 width=24) (actual
time=0.032..0.033 rows=0 loops=1)
  Recheck Cond: ((i5 = 123451) AND (i2 = 898732))
  -> BitmapAnd  (cost=24.34..24.34 rows=2 width=0) (actual time=0.029..0.030 rows=0
loops=1)
    -> Bitmap Index Scan on btreeidx5  (cost=0.00..12.04 rows=500 width=0)
(actual time=0.029..0.029 rows=0 loops=1)
        Index Cond: (i5 = 123451)
    -> Bitmap Index Scan on btreeidx2  (cost=0.00..12.04 rows=500 width=0) (never
executed)
        Index Cond: (i2 = 898732)
Planning Time: 0.537 ms
Execution Time: 0.064 ms
(9 rows)

```

Although this query runs much faster than with either of the single indexes, we pay a penalty in index size. Each of the single-column btree indexes occupies 2 MB, so the total space needed is 12 MB, eight times the space used by the bloom index.

### F.5.3. Operator Class Interface

An operator class for bloom indexes requires only a hash function for the indexed data type and an equality operator for searching. This example shows the operator class definition for the `text` data type:

```

CREATE OPERATOR CLASS text_ops
DEFAULT FOR TYPE text USING bloom AS
    OPERATOR      1      =(text, text),
    FUNCTION      1      hashtext(text);

```

### F.5.4. Limitations

- Only operator classes for `int4` and `text` are included with the module.
- Only the `=` operator is supported for search. But it is possible to add support for arrays with union and intersection operations in the future.
- `bloom` access method doesn't support `UNIQUE` indexes.
- `bloom` access method doesn't support searching for `NULL` values.

### F.5.5. Authors

Teodor Sigaev <teodor@postgrespro.ru>, Postgres Professional, Moscow, Russia

Oleg Bartunov <obartunov@postgrespro.ru>, Postgres Professional, Moscow, Russia

## F.6. btree\_gin

`btree_gin` provides sample GIN operator classes that implement B-tree equivalent behavior for the data types `int2`, `int4`, `int8`, `float4`, `float8`, `timestamp with time zone`, `timestamp without time zone`, `time with time zone`, `time without time zone`, `date`, `interval`, `oid`, `money`, `"char"`, `varchar`, `text`, `bytea`, `bit`, `varbit`, `macaddr`, `macaddr8`, `inet`, `cidr`, `uuid`, `name`, `bool`, `bpchar`, and all enum types.

In general, these operator classes will not outperform the equivalent standard B-tree index methods, and they lack one major feature of the standard B-tree code: the ability to enforce uniqueness. However, they are useful for GIN testing and as a base for developing other GIN operator classes. Also, for queries that test both a GIN-indexable column and a B-tree-indexable column, it might be more efficient to create a multicolumn GIN index that uses one of these operator classes than to create two separate indexes that would have to be combined via bitmap ANDing.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.6.1. Example Usage

```
CREATE TABLE test (a int4);
-- create index
CREATE INDEX testidx ON test USING GIN (a);
-- query
SELECT * FROM test WHERE a < 10;
```

### F.6.2. Authors

Teodor Sigaev (<teodor@stack.net>) and Oleg Bartunov (<oleg@sai.msu.su>). See <http://www.sai.msu.su/~megeera/oddmuse/index.cgi/Gin> for additional information.

## F.7. btree\_gist

`btree_gist` provides GiST index operator classes that implement B-tree equivalent behavior for the data types `int2`, `int4`, `int8`, `float4`, `float8`, `numeric`, `timestamp with time zone`, `timestamp without time zone`, `time with time zone`, `time without time zone`, `date`, `interval`, `oid`, `money`, `char`, `varchar`, `text`, `bytea`, `bit`, `varbit`, `macaddr`, `macaddr8`, `inet`, `cidr`, `uuid`, and all enum types.

In general, these operator classes will not outperform the equivalent standard B-tree index methods, and they lack one major feature of the standard B-tree code: the ability to enforce uniqueness. However, they provide some other features that are not available with a B-tree index, as described below. Also, these operator classes are useful when a multicolumn GiST index is needed, wherein some of the columns are of data types that are only indexable with GiST but other columns are just simple data types. Lastly, these operator classes are useful for GiST testing and as a base for developing other GiST operator classes.

In addition to the typical B-tree search operators, `btree_gist` also provides index support for `<>` (“not equals”). This may be useful in combination with an [exclusion constraint](#), as described below.

Also, for data types for which there is a natural distance metric, `btree_gist` defines a distance operator `<->`, and provides GiST index support for nearest-neighbor searches using this operator. Distance operators are provided for `int2`, `int4`, `int8`, `float4`, `float8`, `timestamp with time zone`, `timestamp without time zone`, `time without time zone`, `date`, `interval`, `oid`, and `money`.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.7.1. Example Usage

Simple example using `btree_gist` instead of `btree`:

```
CREATE TABLE test (a int4);
-- create index
CREATE INDEX testidx ON test USING GIST (a);
-- query
SELECT * FROM test WHERE a < 10;
-- nearest-neighbor search: find the ten entries closest to "42"
SELECT *, a <-> 42 AS dist FROM test ORDER BY a <-> 42 LIMIT 10;
```

Use an [exclusion constraint](#) to enforce the rule that a cage at a zoo can contain only one kind of animal:

```
=> CREATE TABLE zoo (
  cage    INTEGER,
  animal  TEXT,
  EXCLUDE USING GIST (cage WITH =, animal WITH <>)
);

=> INSERT INTO zoo VALUES(123, 'zebra');
INSERT 0 1
=> INSERT INTO zoo VALUES(123, 'zebra');
INSERT 0 1
=> INSERT INTO zoo VALUES(123, 'lion');
ERROR:  conflicting key value violates exclusion constraint "zoo_cage_animal_excl"
DETAIL:  Key (cage, animal)=(123, lion) conflicts with existing key (cage,
        animal)=(123, zebra).
=> INSERT INTO zoo VALUES(124, 'lion');
INSERT 0 1
```

## F.7.2. Authors

Teodor Sigaev (<teodor@stack.net>), Oleg Bartunov (<oleg@sai.msu.su>), Janko Richter (<jankorichter@yahoo.de>), and Paul Jungwirth (<pj@illuminatedcomputing.com>). See <http://www.sai.msu.su/~megera/postgres/gist/> for additional information.

## F.8. citext

The `citext` module provides a case-insensitive character string type, `citext`. Essentially, it internally calls `lower` when comparing values. Otherwise, it behaves almost exactly like `text`.

### Tip

Consider using *nondeterministic collations* (see [Section 22.2.2.4](#)) instead of this module. They can be used for case-insensitive comparisons, accent-insensitive comparisons, and other combinations, and they handle more Unicode special cases correctly.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.8.1. Rationale

The standard approach to doing case-insensitive matches in Postgres Pro has been to use the `lower` function when comparing values, for example

```
SELECT * FROM tab WHERE lower(col) = LOWER(?);
```

This works reasonably well, but has a number of drawbacks:

- It makes your SQL statements verbose, and you always have to remember to use `lower` on both the column and the query value.
- It won't use an index, unless you create a functional index using `lower`.
- If you declare a column as `UNIQUE` or `PRIMARY KEY`, the implicitly generated index is case-sensitive. So it's useless for case-insensitive searches, and it won't enforce uniqueness case-insensitively.

The `citext` data type allows you to eliminate calls to `lower` in SQL queries, and allows a primary key to be case-insensitive. `citext` is locale-aware, just like `text`, which means that the matching of upper case and lower case characters is dependent on the rules of the database's `LC_CTYPE` setting. Again, this

behavior is identical to the use of `lower` in queries. But because it's done transparently by the data type, you don't have to remember to do anything special in your queries.

## F.8.2. How to Use It

Here's a simple example of usage:

```
CREATE TABLE users (  
    nick CITEXT PRIMARY KEY,  
    pass TEXT NOT NULL  
);  
  
INSERT INTO users VALUES ( 'larry', sha256(random)::text::bytea );  
INSERT INTO users VALUES ( 'Tom', sha256(random)::text::bytea );  
INSERT INTO users VALUES ( 'Damian', sha256(random)::text::bytea );  
INSERT INTO users VALUES ( 'NEAL', sha256(random)::text::bytea );  
INSERT INTO users VALUES ( 'Bjørn', sha256(random)::text::bytea );  
  
SELECT * FROM users WHERE nick = 'Larry';
```

The `SELECT` statement will return one tuple, even though the `nick` column was set to `larry` and the query was for `Larry`.

## F.8.3. String Comparison Behavior

`citext` performs comparisons by converting each string to lower case (as though `lower` were called) and then comparing the results normally. Thus, for example, two strings are considered equal if `lower` would produce identical results for them.

In order to emulate a case-insensitive collation as closely as possible, there are `citext`-specific versions of a number of string-processing operators and functions. So, for example, the regular expression operators `~` and `~*` exhibit the same behavior when applied to `citext`: they both match case-insensitively. The same is true for `!~` and `!~*`, as well as for the `LIKE` operators `~~` and `~~*`, and `!~~` and `!~~*`. If you'd like to match case-sensitively, you can cast the operator's arguments to `text`.

Similarly, all of the following functions perform matching case-insensitively if their arguments are `citext`:

- `regexp_match()`
- `regexp_matches()`
- `regexp_replace()`
- `regexp_split_to_array()`
- `regexp_split_to_table()`
- `replace()`
- `split_part()`
- `strpos()`
- `translate()`

For the `regexp` functions, if you want to match case-sensitively, you can specify the `"c"` flag to force a case-sensitive match. Otherwise, you must cast to `text` before using one of these functions if you want case-sensitive behavior.

## F.8.4. Limitations

- `citext`'s case-folding behavior depends on the `LC_CTYPE` setting of your database. How it compares values is therefore determined when the database is created. It is not truly case-insensitive in

the terms defined by the Unicode standard. Effectively, what this means is that, as long as you're happy with your collation, you should be happy with `citext`'s comparisons. But if you have data in different languages stored in your database, users of one language may find their query results are not as expected if the collation is for another language.

- As of PostgreSQL 9.1, you can attach a `COLLATE` specification to `citext` columns or data values. Currently, `citext` operators will honor a non-default `COLLATE` specification while comparing case-folded strings, but the initial folding to lower case is always done according to the database's `LC_CTYPE` setting (that is, as though `COLLATE "default"` were given). This may be changed in a future release so that both steps follow the input `COLLATE` specification.
- `citext` is not as efficient as `text` because the operator functions and the B-tree comparison functions must make copies of the data and convert it to lower case for comparisons. Also, only `text` can support B-Tree deduplication. However, `citext` is slightly more efficient than using `lower` to get case-insensitive matching.
- `citext` doesn't help much if you need data to compare case-sensitively in some contexts and case-insensitively in other contexts. The standard answer is to use the `text` type and manually use the `lower` function when you need to compare case-insensitively; this works all right if case-insensitive comparison is needed only infrequently. If you need case-insensitive behavior most of the time and case-sensitive infrequently, consider storing the data as `citext` and explicitly casting the column to `text` when you want case-sensitive comparison. In either situation, you will need two indexes if you want both types of searches to be fast.
- The schema containing the `citext` operators must be in the current `search_path` (typically `public`); if it is not, the normal case-sensitive `text` operators will be invoked instead.
- The approach of lower-casing strings for comparison does not handle some Unicode special cases correctly, for example when one upper-case letter has two lower-case letter equivalents. Unicode distinguishes between *case mapping* and *case folding* for this reason. Use nondeterministic collations instead of `citext` to handle that correctly.

## F.8.5. Author

David E. Wheeler <david@kineticcode.com>

Inspired by the original `citext` module by Donald Fraser.

## F.9. cube

This module implements a data type `cube` for representing multidimensional cubes.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.9.1. Syntax

Table F.2 shows the valid external representations for the `cube` type.  $x$ ,  $y$ , etc. denote floating-point numbers.

**Table F.2. Cube External Representations**

External Syntax	Meaning
$x$	A one-dimensional point (or, zero-length one-dimensional interval)
$( x )$	Same as above
$x1, x2, \dots, xn$	A point in n-dimensional space, represented internally as a zero-volume cube
$( x1, x2, \dots, xn )$	Same as above

External Syntax	Meaning
$(x), (y)$	A one-dimensional interval starting at $x$ and ending at $y$ or vice versa; the order does not matter
$[(x), (y)]$	Same as above
$(x_1, \dots, x_n), (y_1, \dots, y_n)$	An $n$ -dimensional cube represented by a pair of its diagonally opposite corners
$[(x_1, \dots, x_n), (y_1, \dots, y_n)]$	Same as above

It does not matter which order the opposite corners of a cube are entered in. The `cube` functions automatically swap values if needed to create a uniform “lower left — upper right” internal representation. When the corners coincide, `cube` stores only one corner along with an “is point” flag to avoid wasting space.

White space is ignored on input, so  $[(x), (y)]$  is the same as  $[(x), (y)]$ .

## F.9.2. Precision

Values are stored internally as 64-bit floating point numbers. This means that numbers with more than about 16 significant digits will be truncated.

## F.9.3. Usage

Table F.3 shows the specialized operators provided for type `cube`.

**Table F.3. Cube Operators**

Operator	Description
<code>cube &amp;&amp; cube</code>	<code>→ boolean</code> Do the cubes overlap?
<code>cube @&gt; cube</code>	<code>→ boolean</code> Does the first cube contain the second?
<code>cube &lt;@ cube</code>	<code>→ boolean</code> Is the first cube contained in the second?
<code>cube -&gt; integer</code>	<code>→ float8</code> Extracts the $n$ -th coordinate of the cube (counting from 1).
<code>cube ~&gt; integer</code>	<code>→ float8</code> Extracts the $n$ -th coordinate of the cube, counting in the following way: $n = 2 * k - 1$ means lower bound of $k$ -th dimension, $n = 2 * k$ means upper bound of $k$ -th dimension. Negative $n$ denotes the inverse value of the corresponding positive coordinate. This operator is designed for KNN-GiST support.
<code>cube &lt;-&gt; cube</code>	<code>→ float8</code> Computes the Euclidean distance between the two cubes.
<code>cube &lt;#&gt; cube</code>	<code>→ float8</code> Computes the taxicab (L-1 metric) distance between the two cubes.
<code>cube &lt;=&gt; cube</code>	<code>→ float8</code> Computes the Chebyshev (L-inf metric) distance between the two cubes.

(Before PostgreSQL 8.2, the containment operators `@>` and `<@` were respectively called `@` and `~`. These names are still available, but are deprecated and will eventually be retired. Notice that the old names are reversed from the convention formerly followed by the core geometric data types!)

In addition to the above operators, the usual comparison operators shown in [Table 9.1](#) are available for type `cube`. These operators first compare the first coordinates, and if those are equal, compare the second coordinates, etc. They exist mainly to support the b-tree index operator class for `cube`, which can be useful for example if you would like a `UNIQUE` constraint on a `cube` column. Otherwise, this ordering is not of much practical use.

The `cube` module also provides a GiST index operator class for `cube` values. A `cube` GiST index can be used to search for values using the `=`, `&&`, `@>`, and `<@` operators in `WHERE` clauses.

In addition, a `cube` GiST index can be used to find nearest neighbors using the metric operators `<->`, `<#>`, and `<=>` in `ORDER BY` clauses. For example, the nearest neighbor of the 3-D point (0.5, 0.5, 0.5) could be found efficiently with:

```
SELECT c FROM test ORDER BY c <-> cube(array[0.5,0.5,0.5]) LIMIT 1;
```

The `~>` operator can also be used in this way to efficiently retrieve the first few values sorted by a selected coordinate. For example, to get the first few cubes ordered by the first coordinate (lower left corner) ascending one could use the following query:

```
SELECT c FROM test ORDER BY c ~> 1 LIMIT 5;
```

And to get 2-D cubes ordered by the first coordinate of the upper right corner descending:

```
SELECT c FROM test ORDER BY c ~> 3 DESC LIMIT 5;
```

[Table F.4](#) shows the available functions.

**Table F.4. Cube Functions**

Function	Description	Example(s)
<code>cube ( float8 )</code>	<code>→ cube</code> Makes a one dimensional cube with both coordinates the same.	<code>cube (1) → (1)</code>
<code>cube ( float8, float8 )</code>	<code>→ cube</code> Makes a one dimensional cube.	<code>cube (1,2) → (1), (2)</code>
<code>cube ( float8[] )</code>	<code>→ cube</code> Makes a zero-volume cube using the coordinates defined by the array.	<code>cube (ARRAY[1,2,3]) → (1, 2, 3)</code>
<code>cube ( float8[], float8[] )</code>	<code>→ cube</code> Makes a cube with upper right and lower left coordinates as defined by the two arrays, which must be of the same length.	<code>cube (ARRAY[1,2], ARRAY[3,4]) → (1, 2), (3, 4)</code>
<code>cube ( cube, float8 )</code>	<code>→ cube</code> Makes a new cube by adding a dimension on to an existing cube, with the same values for both endpoints of the new coordinate. This is useful for building cubes piece by piece from calculated values.	<code>cube ('(1,2), (3,4) '::cube, 5) → (1, 2, 5), (3, 4, 5)</code>
<code>cube ( cube, float8, float8 )</code>	<code>→ cube</code> Makes a new cube by adding a dimension on to an existing cube. This is useful for building cubes piece by piece from calculated values.	<code>cube ('(1,2), (3,4) '::cube, 5, 6) → (1, 2, 5), (3, 4, 6)</code>
<code>cube_dim ( cube )</code>	<code>→ integer</code>	

<b>Function</b>	<b>Description</b>	<b>Example(s)</b>
	Returns the number of dimensions of the cube.	<code>cube_dim(' (1,2), (3,4)')</code> → 2
<code>cube_ll_coord</code>	( <code>cube</code> , <code>integer</code> ) → <code>float8</code> Returns the <i>n</i> -th coordinate value for the lower left corner of the cube.	<code>cube_ll_coord(' (1,2), (3,4)', 2)</code> → 2
<code>cube_ur_coord</code>	( <code>cube</code> , <code>integer</code> ) → <code>float8</code> Returns the <i>n</i> -th coordinate value for the upper right corner of the cube.	<code>cube_ur_coord(' (1,2), (3,4)', 2)</code> → 4
<code>cube_is_point</code>	( <code>cube</code> ) → <code>boolean</code> Returns true if the cube is a point, that is, the two defining corners are the same.	<code>cube_is_point(cube(1,1))</code> → t
<code>cube_distance</code>	( <code>cube</code> , <code>cube</code> ) → <code>float8</code> Returns the distance between two cubes. If both cubes are points, this is the normal distance function.	<code>cube_distance(' (1,2)', ' (3,4)')</code> → 2.8284271247461903
<code>cube_subset</code>	( <code>cube</code> , <code>integer[]</code> ) → <code>cube</code> Makes a new cube from an existing cube, using a list of dimension indexes from an array. Can be used to extract the endpoints of a single dimension, or to drop dimensions, or to reorder them as desired.	<code>cube_subset(cube(' (1,3,5), (6,7,8)'), ARRAY[2])</code> → (3), (7) <code>cube_subset(cube(' (1,3,5), (6,7,8)'), ARRAY[3,2,1,1])</code> → (5, 3, 1, 1), (8, 7, 6, 6)
<code>cube_union</code>	( <code>cube</code> , <code>cube</code> ) → <code>cube</code> Produces the union of two cubes.	<code>cube_union(' (1,2)', ' (3,4)')</code> → (1, 2), (3, 4)
<code>cube_inter</code>	( <code>cube</code> , <code>cube</code> ) → <code>cube</code> Produces the intersection of two cubes.	<code>cube_inter(' (1,2)', ' (3,4)')</code> → (3, 4), (1, 2)
<code>cube_enlarge</code>	( <i>c</i> <code>cube</code> , <i>r</i> <code>double</code> , <i>n</i> <code>integer</code> ) → <code>cube</code> Increases the size of the cube by the specified radius <i>r</i> in at least <i>n</i> dimensions. If the radius is negative the cube is shrunk instead. All defined dimensions are changed by the radius <i>r</i> . Lower-left coordinates are decreased by <i>r</i> and upper-right coordinates are increased by <i>r</i> . If a lower-left coordinate is increased to more than the corresponding upper-right coordinate (this can only happen when <i>r</i> < 0) then both coordinates are set to their average. If <i>n</i> is greater than the number of defined dimensions and the cube is being enlarged ( <i>r</i> > 0), then extra dimensions are added to make <i>n</i> altogether; 0 is used as the initial value for the extra coordinates. This function is useful for creating bounding boxes around a point for searching for nearby points.	<code>cube_enlarge(' (1,2), (3,4)', 0.5, 3)</code> → (0.5, 1.5, -0.5), (3.5, 4.5, 0.5)

## F.9.4. Defaults

I believe this union:

```
select cube_union(' (0,5,2), (2,3,1)', '0');
cube_union
```

```
-----  
(0, 0, 0), (2, 5, 2)  
(1 row)
```

does not contradict common sense, neither does the intersection

```
select cube_inter('(0,-1), (1,1)', '(-2), (2)');  
cube_inter  
-----  
(0, 0), (1, 0)  
(1 row)
```

In all binary operations on differently-dimensional cubes, I assume the lower-dimensional one to be a Cartesian projection, i. e., having zeroes in place of coordinates omitted in the string representation. The above examples are equivalent to:

```
cube_union('(0,5,2), (2,3,1)', '(0,0,0), (0,0,0)');  
cube_inter('(0,-1), (1,1)', '(-2,0), (2,0)');
```

The following containment predicate uses the point syntax, while in fact the second argument is internally represented by a box. This syntax makes it unnecessary to define a separate point type and functions for (box,point) predicates.

```
select cube_contains('(0,0), (1,1)', '0.5,0.5');  
cube_contains  
-----  
t  
(1 row)
```

## F.9.5. Notes

For examples of usage, see the regression test `sql/cube.sql`.

To make it harder for people to break things, there is a limit of 100 on the number of dimensions of cubes. This is set in `cubedata.h` if you need something bigger.

## F.9.6. Credits

Original author: Gene Selkov, Jr. <selkovjr@mcs.anl.gov>, Mathematics and Computer Science Division, Argonne National Laboratory.

My thanks are primarily to Prof. Joe Hellerstein (<https://dsf.berkeley.edu/jmh/>) for elucidating the gist of the GiST (<http://gist.cs.berkeley.edu/>), and to his former student Andy Dong for his example written for *Illustra*. I am also grateful to all Postgres developers, present and past, for enabling myself to create my own world and live undisturbed in it. And I would like to acknowledge my gratitude to Argonne Lab and to the U.S. Department of Energy for the years of faithful support of my database research.

Minor updates to this package were made by Bruno Wolff III <bruno@wolff.to> in August/September of 2002. These include changing the precision from single precision to double precision and adding some new functions.

Additional updates were made by Joshua Reich <josh@root.net> in July 2006. These include `cube(float8[], float8[])` and cleaning up the code to use the V1 call protocol instead of the deprecated V0 protocol.

## F.10. dblink

`dblink` is a module that supports connections to other Postgres Pro databases from within a database session.

See also `postgres_fdw`, which provides roughly the same functionality using a more modern and standards-compliant infrastructure.

## dblink\_connect

`dblink_connect` — opens a persistent connection to a remote database

### Synopsis

```
dblink_connect(text connstr) returns text
dblink_connect(text connname, text connstr) returns text
```

### Description

`dblink_connect()` establishes a connection to a remote Postgres Pro database. The server and database to be contacted are identified through a standard libpq connection string. Optionally, a name can be assigned to the connection. Multiple named connections can be open at once, but only one unnamed connection is permitted at a time. The connection will persist until closed or until the database session is ended.

The connection string may also be the name of an existing foreign server. It is recommended to use the foreign-data wrapper `dblink_fdw` when defining the foreign server. See the example below, as well as [CREATE SERVER](#) and [CREATE USER MAPPING](#).

### Arguments

*connname*

The name to use for this connection; if omitted, an unnamed connection is opened, replacing any existing unnamed connection.

*connstr*

libpq-style connection info string, for example `hostaddr=127.0.0.1 port=5432 dbname=mydb user=postgres password=mypasswd options=-csearch_path=`. For details see [Section 31.1.1](#). Alternatively, the name of a foreign server.

### Return Value

Returns status, which is always OK (since any error causes the function to throw an error instead of returning).

### Notes

If untrusted users have access to a database that has not adopted a [secure schema usage pattern](#), begin each session by removing publicly-writable schemas from `search_path`. One could, for example, add `options=-csearch_path=` to *connstr*. This consideration is not specific to `dblink`; it applies to every interface for executing arbitrary SQL commands.

Only superusers may use `dblink_connect` to create non-password-authenticated connections. If non-superusers need this capability, use `dblink_connect_u` instead.

It is unwise to choose connection names that contain equal signs, as this opens a risk of confusion with connection info strings in other `dblink` functions.

### Examples

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
 dblink_connect
-----
      OK
(1 row)

SELECT dblink_connect('myconn', 'dbname=postgres options=-csearch_path=');
```

```

dblink_connect
-----
OK
(1 row)

-- FOREIGN DATA WRAPPER functionality
-- Note: local connection must require password authentication for this to work
properly
--      Otherwise, you will receive the following error from dblink_connect():
--      ERROR: password is required
--      DETAIL: Non-superuser cannot connect if the server does not request a
password.
--      HINT: Target server's authentication method must be changed.

CREATE SERVER fdtest FOREIGN DATA WRAPPER dblink_fdw OPTIONS (hostaddr '127.0.0.1',
  dbname 'contrib_regression');

CREATE USER regress_dblink_user WITH PASSWORD 'secret';
CREATE USER MAPPING FOR regress_dblink_user SERVER fdtest OPTIONS (user
  'regress_dblink_user', password 'secret');
GRANT USAGE ON FOREIGN SERVER fdtest TO regress_dblink_user;
GRANT SELECT ON TABLE foo TO regress_dblink_user;

\set ORIGINAL_USER :USER
\c - regress_dblink_user
SELECT dblink_connect('myconn', 'fdtest');
  dblink_connect
-----
OK
(1 row)

SELECT * FROM dblink('myconn', 'SELECT * FROM foo') AS t(a int, b text, c text[]);
 a | b | c
-----+-----+-----
 0 | a | {a0,b0,c0}
 1 | b | {a1,b1,c1}
 2 | c | {a2,b2,c2}
 3 | d | {a3,b3,c3}
 4 | e | {a4,b4,c4}
 5 | f | {a5,b5,c5}
 6 | g | {a6,b6,c6}
 7 | h | {a7,b7,c7}
 8 | i | {a8,b8,c8}

DROP SERVER fdtest;

```

## **dblink\_connect\_u**

`dblink_connect_u` — opens a persistent connection to a remote database, insecurely

### **Synopsis**

```
dblink_connect_u(text connstr) returns text  
dblink_connect_u(text connname, text connstr) returns text
```

### **Description**

`dblink_connect_u()` is identical to `dblink_connect()`, except that it will allow non-superusers to connect using any authentication method.

If the remote server selects an authentication method that does not involve a password, then impersonation and subsequent escalation of privileges can occur, because the session will appear to have originated from the user as which the local Postgres Pro server runs. Also, even if the remote server does demand a password, it is possible for the password to be supplied from the server environment, such as a `~/.pgpass` file belonging to the server's user. This opens not only a risk of impersonation, but the possibility of exposing a password to an untrustworthy remote server. Therefore, `dblink_connect_u()` is initially installed with all privileges revoked from `PUBLIC`, making it un-callable except by superusers. In some situations it may be appropriate to grant `EXECUTE` permission for `dblink_connect_u()` to specific users who are considered trustworthy, but this should be done with care. It is also recommended that any `~/.pgpass` file belonging to the server's user *not* contain any records specifying a wildcard host name.

For further details see `dblink_connect()`.

## **dblink\_disconnect**

`dblink_disconnect` — closes a persistent connection to a remote database

### **Synopsis**

```
dblink_disconnect() returns text
dblink_disconnect(text connname) returns text
```

### **Description**

`dblink_disconnect()` closes a connection previously opened by `dblink_connect()`. The form with no arguments closes an unnamed connection.

### **Arguments**

*connname*

The name of a named connection to be closed.

### **Return Value**

Returns status, which is always `OK` (since any error causes the function to throw an error instead of returning).

### **Examples**

```
SELECT dblink_disconnect();
 dblink_disconnect
-----
      OK
(1 row)
```

```
SELECT dblink_disconnect('myconn');
 dblink_disconnect
-----
      OK
(1 row)
```

## dblink

`dblink` — executes a query in a remote database

## Synopsis

```
dblink(text connname, text sql [, bool fail_on_error]) returns setof record
dblink(text connstr, text sql [, bool fail_on_error]) returns setof record
dblink(text sql [, bool fail_on_error]) returns setof record
```

## Description

`dblink` executes a query (usually a `SELECT`, but it can be any SQL statement that returns rows) in a remote database.

When two `text` arguments are given, the first one is first looked up as a persistent connection's name; if found, the command is executed on that connection. If not found, the first argument is treated as a connection info string as for `dblink_connect`, and the indicated connection is made just for the duration of this command.

## Arguments

*connname*

Name of the connection to use; omit this parameter to use the unnamed connection.

*connstr*

A connection info string, as previously described for `dblink_connect`.

*sql*

The SQL query that you wish to execute in the remote database, for example `select * from foo`.

*fail\_on\_error*

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a `NOTICE`, and the function returns no rows.

## Return Value

The function returns the row(s) produced by the query. Since `dblink` can be used with any query, it is declared to return `record`, rather than specifying any particular set of columns. This means that you must specify the expected set of columns in the calling query — otherwise Postgres Pro would not know what to expect. Here is an example:

```
SELECT *
FROM dblink('dbname=mydb options=-csearch_path=',
            'select proname, prosrc from pg_proc')
AS t1(proname name, prosrc text)
WHERE proname LIKE 'bytea%';
```

The “alias” part of the `FROM` clause must specify the column names and types that the function will return. (Specifying column names in an alias is actually standard SQL syntax, but specifying column types is a Postgres Pro extension.) This allows the system to understand what `*` should expand to, and what `proname` in the `WHERE` clause refers to, in advance of trying to execute the function. At run time, an error will be thrown if the actual query result from the remote database does not have the same number of columns shown in the `FROM` clause. The column names need not match, however, and `dblink` does not insist on exact type matches either. It will succeed so long as the returned data strings are valid input for the column type declared in the `FROM` clause.

## Notes

A convenient way to use `dblink` with predetermined queries is to create a view. This allows the column type information to be buried in the view, instead of having to spell it out in every query. For example,

```
CREATE VIEW myremote_pg_proc AS
  SELECT *
    FROM dblink('dbname=postgres options=-csearch_path=',
               'select proname, prosrc from pg_proc')
    AS t1(proname name, prosrc text);

SELECT * FROM myremote_pg_proc WHERE proname LIKE 'bytea%';
```

## Examples

```
SELECT * FROM dblink('dbname=postgres options=-csearch_path=',
                    'select proname, prosrc from pg_proc')
  AS t1(proname name, prosrc text) WHERE proname LIKE 'bytea%';
proname | prosrc
```

proname	prosrc
byteacat	byteacat
byteaeq	byteaeq
bytealt	bytealt
byteale	byteale
byteagt	byteagt
byteage	byteage
byteane	byteane
byteacmp	byteacmp
bytealike	bytealike
byteanlike	byteanlike
byteain	byteain
byteaout	byteaout

(12 rows)

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
dblink_connect
-----
OK
(1 row)
```

```
SELECT * FROM dblink('select proname, prosrc from pg_proc')
  AS t1(proname name, prosrc text) WHERE proname LIKE 'bytea%';
proname | prosrc
```

proname	prosrc
byteacat	byteacat
byteaeq	byteaeq
bytealt	bytealt
byteale	byteale
byteagt	byteagt
byteage	byteage
byteane	byteane
byteacmp	byteacmp
bytealike	bytealike
byteanlike	byteanlike
byteain	byteain
byteaout	byteaout

(12 rows)

```
SELECT dblink_connect('myconn', 'dbname=regression options=-csearch_path=');
```

dblink\_connect

-----  
OK  
(1 row)

```
SELECT * FROM dblink('myconn', 'select proname, prosrc from pg_proc')
AS t1(proname name, prosrc text) WHERE proname LIKE 'bytea%';
```

```
proname | prosrc
-----+-----
bytearecv | bytearecv
byteasend | byteasend
byteale | byteale
byteagt | byteagt
byteage | byteage
byteane | byteane
byteacmp | byteacmp
bytealike | bytealike
byteanlike | byteanlike
byteacat | byteacat
byteaeq | byteaeq
bytealt | bytealt
byteain | byteain
byteaout | byteaout
(14 rows)
```

## dblink\_exec

`dblink_exec` — executes a command in a remote database

### Synopsis

```
dblink_exec(text connname, text sql [, bool fail_on_error]) returns text
dblink_exec(text connstr, text sql [, bool fail_on_error]) returns text
dblink_exec(text sql [, bool fail_on_error]) returns text
```

### Description

`dblink_exec` executes a command (that is, any SQL statement that doesn't return rows) in a remote database.

When two `text` arguments are given, the first one is first looked up as a persistent connection's name; if found, the command is executed on that connection. If not found, the first argument is treated as a connection info string as for `dblink_connect`, and the indicated connection is made just for the duration of this command.

### Arguments

*connname*

Name of the connection to use; omit this parameter to use the unnamed connection.

*connstr*

A connection info string, as previously described for `dblink_connect`.

*sql*

The SQL command that you wish to execute in the remote database, for example `insert into foo values (0, 'a', '{"a0","b0","c0"}')`.

*fail\_on\_error*

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function's return value is set to `ERROR`.

### Return Value

Returns status, either the command's status string or `ERROR`.

### Examples

```
SELECT dblink_connect('dbname=dblink_test_standby');
 dblink_connect
-----
OK
(1 row)

SELECT dblink_exec('insert into foo values(21, 'z', '{"a0","b0","c0"}');');
 dblink_exec
-----
INSERT 943366 1
(1 row)

SELECT dblink_connect('myconn', 'dbname=regression');
 dblink_connect
```

-----

OK  
(1 row)

```
SELECT dblink_exec('myconn', 'insert into foo values(21, ''z'',  
  ''{"a0","b0","c0}''');');  
      dblink_exec
```

-----

INSERT 6432584 1  
(1 row)

```
SELECT dblink_exec('myconn', 'insert into pg_class values (''foo''),false);  
NOTICE:  sql error  
DETAIL:  ERROR:  null value in column "relnamespace" violates not-null constraint
```

dblink\_exec

-----

ERROR  
(1 row)

## dblink\_open

`dblink_open` — opens a cursor in a remote database

### Synopsis

```
dblink_open(text cursorname, text sql [, bool fail_on_error]) returns text
dblink_open(text connname, text cursorname, text sql [, bool fail_on_error]) returns
text
```

### Description

`dblink_open()` opens a cursor in a remote database. The cursor can subsequently be manipulated with `dblink_fetch()` and `dblink_close()`.

### Arguments

*connname*

Name of the connection to use; omit this parameter to use the unnamed connection.

*cursorname*

The name to assign to this cursor.

*sql*

The `SELECT` statement that you wish to execute in the remote database, for example `select * from pg_class`.

*fail\_on\_error*

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function's return value is set to `ERROR`.

### Return Value

Returns status, either `OK` or `ERROR`.

### Notes

Since a cursor can only persist within a transaction, `dblink_open` starts an explicit transaction block (`BEGIN`) on the remote side, if the remote side was not already within a transaction. This transaction will be closed again when the matching `dblink_close` is executed. Note that if you use `dblink_exec` to change data between `dblink_open` and `dblink_close`, and then an error occurs or you use `dblink_disconnect` before `dblink_close`, your change *will be lost* because the transaction will be aborted.

### Examples

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
dblink_connect
-----
OK
(1 row)
```

```
SELECT dblink_open('foo', 'select proname, prosrc from pg_proc');
dblink_open
-----
OK
```

(1 row)

## **dblink\_fetch**

`dblink_fetch` — returns rows from an open cursor in a remote database

### **Synopsis**

```
dblink_fetch(text cursorname, int howmany [, bool fail_on_error]) returns setof record
dblink_fetch(text connname, text cursorname, int howmany [, bool fail_on_error])
  returns setof record
```

### **Description**

`dblink_fetch` fetches rows from a cursor previously established by `dblink_open`.

### **Arguments**

*connname*

Name of the connection to use; omit this parameter to use the unnamed connection.

*cursorname*

The name of the cursor to fetch from.

*howmany*

The maximum number of rows to retrieve. The next *howmany* rows are fetched, starting at the current cursor position, moving forward. Once the cursor has reached its end, no more rows are produced.

*fail\_on\_error*

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function returns no rows.

### **Return Value**

The function returns the row(s) fetched from the cursor. To use this function, you will need to specify the expected set of columns, as previously discussed for `dblink`.

### **Notes**

On a mismatch between the number of return columns specified in the `FROM` clause, and the actual number of columns returned by the remote cursor, an error will be thrown. In this event, the remote cursor is still advanced by as many rows as it would have been if the error had not occurred. The same is true for any other error occurring in the local query after the remote `FETCH` has been done.

### **Examples**

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
dblink_connect
```

```
-----
OK
(1 row)
```

```
SELECT dblink_open('foo', 'select proname, prosrc from pg_proc where proname like
''bytea%'');
dblink_open
```

```
-----
OK
(1 row)
```

```
SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source text);
  funcname | source
-----+-----
 byteacat | byteacat
 byteacmp | byteacmp
 byteaeq  | byteaeq
 byteage  | byteage
 byteagt  | byteagt
(5 rows)
```

```
SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source text);
  funcname | source
-----+-----
 byteain  | byteain
 byteale  | byteale
 bytealike| bytealike
 bytealt  | bytealt
 byteane  | byteane
(5 rows)
```

```
SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source text);
  funcname | source
-----+-----
 byteanlike | byteanlike
 byteaout  | byteaout
(2 rows)
```

```
SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source text);
  funcname | source
-----+-----
(0 rows)
```

## dblink\_close

`dblink_close` — closes a cursor in a remote database

### Synopsis

```
dblink_close(text cursorname [, bool fail_on_error]) returns text
dblink_close(text connname, text cursorname [, bool fail_on_error]) returns text
```

### Description

`dblink_close` closes a cursor previously opened with `dblink_open`.

### Arguments

*connname*

Name of the connection to use; omit this parameter to use the unnamed connection.

*cursorname*

The name of the cursor to close.

*fail\_on\_error*

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function's return value is set to `ERROR`.

### Return Value

Returns status, either `OK` or `ERROR`.

### Notes

If `dblink_open` started an explicit transaction block, and this is the last remaining open cursor in this connection, `dblink_close` will issue the matching `COMMIT`.

### Examples

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
dblink_connect
```

```
-----
OK
(1 row)
```

```
SELECT dblink_open('foo', 'select proname, prosrc from pg_proc');
dblink_open
```

```
-----
OK
(1 row)
```

```
SELECT dblink_close('foo');
dblink_close
```

```
-----
OK
(1 row)
```

## **dblink\_get\_connections**

`dblink_get_connections` — returns the names of all open named dblink connections

### **Synopsis**

```
dblink_get_connections() returns text[]
```

### **Description**

`dblink_get_connections` returns an array of the names of all open named dblink connections.

### **Return Value**

Returns a text array of connection names, or NULL if none.

### **Examples**

```
SELECT dblink_get_connections();
```

## **dblink\_error\_message**

`dblink_error_message` — gets last error message on the named connection

### **Synopsis**

`dblink_error_message(text connname)` returns text

### **Description**

`dblink_error_message` fetches the most recent remote error message for a given connection.

### **Arguments**

*connname*

Name of the connection to use.

### **Return Value**

Returns last error message, or OK if there has been no error in this connection.

### **Notes**

When asynchronous queries are initiated by `dblink_send_query`, the error message associated with the connection might not get updated until the server's response message is consumed. This typically means that `dblink_is_busy` or `dblink_get_result` should be called prior to `dblink_error_message`, so that any error generated by the asynchronous query will be visible.

### **Examples**

```
SELECT dblink_error_message('dtest1');
```

## **dblink\_send\_query**

`dblink_send_query` — sends an async query to a remote database

### **Synopsis**

```
dblink_send_query(text connname, text sql) returns int
```

### **Description**

`dblink_send_query` sends a query to be executed asynchronously, that is, without immediately waiting for the result. There must not be an async query already in progress on the connection.

After successfully dispatching an async query, completion status can be checked with `dblink_is_busy`, and the results are ultimately collected with `dblink_get_result`. It is also possible to attempt to cancel an active async query using `dblink_cancel_query`.

### **Arguments**

*connname*

Name of the connection to use.

*sql*

The SQL statement that you wish to execute in the remote database, for example `select * from pg_class`.

### **Return Value**

Returns 1 if the query was successfully dispatched, 0 otherwise.

### **Examples**

```
SELECT dblink_send_query('dtest1', 'SELECT * FROM foo WHERE f1 < 3');
```

## **dblink\_is\_busy**

`dblink_is_busy` — checks if connection is busy with an async query

### **Synopsis**

```
dblink_is_busy(text connname) returns int
```

### **Description**

`dblink_is_busy` tests whether an async query is in progress.

### **Arguments**

*connname*

Name of the connection to check.

### **Return Value**

Returns 1 if connection is busy, 0 if it is not busy. If this function returns 0, it is guaranteed that `dblink_get_result` will not block.

### **Examples**

```
SELECT dblink_is_busy('dtest1');
```

## dblink\_get\_notify

dblink\_get\_notify — retrieve async notifications on a connection

### Synopsis

```
dblink_get_notify() returns setof (notify_name text, be_pid int, extra text)
dblink_get_notify(text connname) returns setof (notify_name text, be_pid int, extra
text)
```

### Description

dblink\_get\_notify retrieves notifications on either the unnamed connection, or on a named connection if specified. To receive notifications via dblink, LISTEN must first be issued, using dblink\_exec. For details see [LISTEN](#) and [NOTIFY](#).

### Arguments

*connname*

The name of a named connection to get notifications on.

### Return Value

Returns setof (notify\_name text, be\_pid int, extra text), or an empty set if none.

### Examples

```
SELECT dblink_exec('LISTEN virtual');
dblink_exec
-----
LISTEN
(1 row)
```

```
SELECT * FROM dblink_get_notify();
notify_name | be_pid | extra
-----+-----+-----
(0 rows)
```

```
NOTIFY virtual;
NOTIFY
```

```
SELECT * FROM dblink_get_notify();
notify_name | be_pid | extra
-----+-----+-----
virtual     | 1229   |
(1 row)
```

## dblink\_get\_result

`dblink_get_result` — gets an async query result

### Synopsis

```
dblink_get_result(text connname [, bool fail_on_error]) returns setof record
```

### Description

`dblink_get_result` collects the results of an asynchronous query previously sent with `dblink_send_query`. If the query is not already completed, `dblink_get_result` will wait until it is.

### Arguments

*connname*

Name of the connection to use.

*fail\_on\_error*

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function returns no rows.

### Return Value

For an async query (that is, a SQL statement returning rows), the function returns the row(s) produced by the query. To use this function, you will need to specify the expected set of columns, as previously discussed for `dblink`.

For an async command (that is, a SQL statement not returning rows), the function returns a single row with a single text column containing the command's status string. It is still necessary to specify that the result will have a single text column in the calling `FROM` clause.

### Notes

This function *must* be called if `dblink_send_query` returned 1. It must be called once for each query sent, and one additional time to obtain an empty set result, before the connection can be used again.

When using `dblink_send_query` and `dblink_get_result`, `dblink` fetches the entire remote query result before returning any of it to the local query processor. If the query returns a large number of rows, this can result in transient memory bloat in the local session. It may be better to open such a query as a cursor with `dblink_open` and then fetch a manageable number of rows at a time. Alternatively, use plain `dblink()`, which avoids memory bloat by spooling large result sets to disk.

### Examples

```
contrib_regression=# SELECT dblink_connect('dtest1', 'dbname=contrib_regression');
dblink_connect
-----
OK
(1 row)

contrib_regression=# SELECT * FROM
contrib_regression=# dblink_send_query('dtest1', 'select * from foo where f1 < 3') AS
t1;
t1
----
1
(1 row)
```

```
contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text,
f3 text[]);
f1 | f2 |      f3
----+-----+-----
 0 | a  | {a0,b0,c0}
 1 | b  | {a1,b1,c1}
 2 | c  | {a2,b2,c2}
(3 rows)
```

```
contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text,
f3 text[]);
f1 | f2 | f3
----+-----+-----
(0 rows)
```

```
contrib_regression=# SELECT * FROM
contrib_regression-# dblink_send_query('dtest1', 'select * from foo where f1 < 3;
select * from foo where f1 > 6') AS t1;
t1
----
 1
(1 row)
```

```
contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text,
f3 text[]);
f1 | f2 |      f3
----+-----+-----
 0 | a  | {a0,b0,c0}
 1 | b  | {a1,b1,c1}
 2 | c  | {a2,b2,c2}
(3 rows)
```

```
contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text,
f3 text[]);
f1 | f2 |      f3
----+-----+-----
 7 | h  | {a7,b7,c7}
 8 | i  | {a8,b8,c8}
 9 | j  | {a9,b9,c9}
10 | k  | {a10,b10,c10}
(4 rows)
```

```
contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text,
f3 text[]);
f1 | f2 | f3
----+-----+-----
(0 rows)
```

## **dblink\_cancel\_query**

`dblink_cancel_query` — cancels any active query on the named connection

### **Synopsis**

`dblink_cancel_query(text connname)` returns text

### **Description**

`dblink_cancel_query` attempts to cancel any query that is in progress on the named connection. Note that this is not certain to succeed (since, for example, the remote query might already have finished). A cancel request simply improves the odds that the query will fail soon. You must still complete the normal query protocol, for example by calling `dblink_get_result`.

### **Arguments**

*connname*

Name of the connection to use.

### **Return Value**

Returns `OK` if the cancel request has been sent, or the text of an error message on failure.

### **Examples**

```
SELECT dblink_cancel_query('dtest1');
```

## dblink\_get\_pkey

`dblink_get_pkey` — returns the positions and field names of a relation's primary key fields

### Synopsis

```
dblink_get_pkey(text relname) returns setof dblink_pkey_results
```

### Description

`dblink_get_pkey` provides information about the primary key of a relation in the local database. This is sometimes useful in generating queries to be sent to remote databases.

### Arguments

*relname*

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example `"FooBar"`; without quotes, the string will be folded to lower case.

### Return Value

Returns one row for each primary key field, or no rows if the relation has no primary key. The result row type is defined as

```
CREATE TYPE dblink_pkey_results AS (position int, colname text);
```

The `position` column simply runs from 1 to *N*; it is the number of the field within the primary key, not the number within the table's columns.

### Examples

```
CREATE TABLE foobar (  
    f1 int,  
    f2 int,  
    f3 int,  
    PRIMARY KEY (f1, f2, f3)  
);  
CREATE TABLE  
  
SELECT * FROM dblink_get_pkey('foobar');  
position | colname  
-----+-----  
        1 | f1  
        2 | f2  
        3 | f3  
(3 rows)
```

## dblink\_build\_sql\_insert

`dblink_build_sql_insert` — builds an `INSERT` statement using a local tuple, replacing the primary key field values with alternative supplied values

### Synopsis

```
dblink_build_sql_insert(text relname,  
                        int2vector primary_key_attnums,  
                        integer num_primary_key_atts,  
                        text[] src_pk_att_vals_array,  
                        text[] tgt_pk_att_vals_array) returns text
```

### Description

`dblink_build_sql_insert` can be useful in doing selective replication of a local table to a remote database. It selects a row from the local table based on primary key, and then builds a SQL `INSERT` command that will duplicate that row, but with the primary key values replaced by the values in the last argument. (To make an exact copy of the row, just specify the same values for the last two arguments.)

### Arguments

*relname*

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example `"FooBar"`; without quotes, the string will be folded to lower case.

*primary\_key\_attnums*

Attribute numbers (1-based) of the primary key fields, for example `1 2`.

*num\_primary\_key\_atts*

The number of primary key fields.

*src\_pk\_att\_vals\_array*

Values of the primary key fields to be used to look up the local tuple. Each field is represented in text form. An error is thrown if there is no local row with these primary key values.

*tgt\_pk\_att\_vals\_array*

Values of the primary key fields to be placed in the resulting `INSERT` command. Each field is represented in text form.

### Return Value

Returns the requested SQL statement as text.

### Notes

As of PostgreSQL 9.0, the attribute numbers in *primary\_key\_attnums* are interpreted as logical column numbers, corresponding to the column's position in `SELECT * FROM relname`. Previous versions interpreted the numbers as physical column positions. There is a difference if any column(s) to the left of the indicated column have been dropped during the lifetime of the table.

### Examples

```
SELECT dblink_build_sql_insert('foo', '1 2', 2, '{"1", "a"}', '{"1", "b''a"}');  
       dblink_build_sql_insert
```

---

```
INSERT INTO foo(f1,f2,f3) VALUES('1','b'a','1')
(1 row)
```

## dblink\_build\_sql\_delete

`dblink_build_sql_delete` — builds a DELETE statement using supplied values for primary key field values

### Synopsis

```
dblink_build_sql_delete(text relname,  
                        int2vector primary_key_attnums,  
                        integer num_primary_key_atts,  
                        text[] tgt_pk_att_vals_array) returns text
```

### Description

`dblink_build_sql_delete` can be useful in doing selective replication of a local table to a remote database. It builds a SQL DELETE command that will delete the row with the given primary key values.

### Arguments

*relname*

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example `"FooBar"`; without quotes, the string will be folded to lower case.

*primary\_key\_attnums*

Attribute numbers (1-based) of the primary key fields, for example `1 2`.

*num\_primary\_key\_atts*

The number of primary key fields.

*tgt\_pk\_att\_vals\_array*

Values of the primary key fields to be used in the resulting DELETE command. Each field is represented in text form.

### Return Value

Returns the requested SQL statement as text.

### Notes

As of PostgreSQL 9.0, the attribute numbers in *primary\_key\_attnums* are interpreted as logical column numbers, corresponding to the column's position in `SELECT * FROM relname`. Previous versions interpreted the numbers as physical column positions. There is a difference if any column(s) to the left of the indicated column have been dropped during the lifetime of the table.

### Examples

```
SELECT dblink_build_sql_delete('"MyFoo"', '1 2', 2, '{"1", "b"}');  
      dblink_build_sql_delete  
-----  
DELETE FROM "MyFoo" WHERE f1='1' AND f2='b'  
(1 row)
```

## dblink\_build\_sql\_update

`dblink_build_sql_update` — builds an UPDATE statement using a local tuple, replacing the primary key field values with alternative supplied values

### Synopsis

```
dblink_build_sql_update(text relname,
                        int2vector primary_key_attnums,
                        integer num_primary_key_atts,
                        text[] src_pk_att_vals_array,
                        text[] tgt_pk_att_vals_array) returns text
```

### Description

`dblink_build_sql_update` can be useful in doing selective replication of a local table to a remote database. It selects a row from the local table based on primary key, and then builds a SQL UPDATE command that will duplicate that row, but with the primary key values replaced by the values in the last argument. (To make an exact copy of the row, just specify the same values for the last two arguments.) The UPDATE command always assigns all fields of the row — the main difference between this and `dblink_build_sql_insert` is that it's assumed that the target row already exists in the remote table.

### Arguments

*relname*

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example `"FooBar"`; without quotes, the string will be folded to lower case.

*primary\_key\_attnums*

Attribute numbers (1-based) of the primary key fields, for example `1 2`.

*num\_primary\_key\_atts*

The number of primary key fields.

*src\_pk\_att\_vals\_array*

Values of the primary key fields to be used to look up the local tuple. Each field is represented in text form. An error is thrown if there is no local row with these primary key values.

*tgt\_pk\_att\_vals\_array*

Values of the primary key fields to be placed in the resulting UPDATE command. Each field is represented in text form.

### Return Value

Returns the requested SQL statement as text.

### Notes

As of PostgreSQL 9.0, the attribute numbers in *primary\_key\_attnums* are interpreted as logical column numbers, corresponding to the column's position in `SELECT * FROM relname`. Previous versions interpreted the numbers as physical column positions. There is a difference if any column(s) to the left of the indicated column have been dropped during the lifetime of the table.

### Examples

```
SELECT dblink_build_sql_update('foo', '1 2', 2, '{"1", "a"}', '{"1", "b"}');
       dblink_build_sql_update
```

---

```
UPDATE foo SET f1='1',f2='b',f3='1' WHERE f1='1' AND f2='b'
(1 row)
```

## F.11. dict\_int

`dict_int` is an example of an add-on dictionary template for full-text search. The motivation for this example dictionary is to control the indexing of integers (signed and unsigned), allowing such numbers to be indexed while preventing excessive growth in the number of unique words, which greatly affects the performance of searching.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.11.1. Configuration

The dictionary accepts three options:

- The `maxlen` parameter specifies the maximum number of digits allowed in an integer word. The default value is 6.
- The `rejectlong` parameter specifies whether an overlength integer should be truncated or ignored. If `rejectlong` is `false` (the default), the dictionary returns the first `maxlen` digits of the integer. If `rejectlong` is `true`, the dictionary treats an overlength integer as a stop word, so that it will not be indexed. Note that this also means that such an integer cannot be searched for.
- The `absval` parameter specifies whether leading “+” or “-” signs should be removed from integer words. The default is `false`. When `true`, the sign is removed before `maxlen` is applied.

### F.11.2. Usage

Installing the `dict_int` extension creates a text search template `intdict_template` and a dictionary `intdict` based on it, with the default parameters. You can alter the parameters, for example

```
mydb# ALTER TEXT SEARCH DICTIONARY intdict (MAXLEN = 4, REJECTLONG = true);
ALTER TEXT SEARCH DICTIONARY
```

or create new dictionaries based on the template.

To test the dictionary, you can try

```
mydb# select ts_lexize('intdict', '12345678');
   ts_lexize
-----
 {123456}
```

but real-world usage will involve including it in a text search configuration as described in [Chapter 12](#). That might look like this:

```
ALTER TEXT SEARCH CONFIGURATION english
  ALTER MAPPING FOR int, uint WITH intdict;
```

## F.12. dict\_xsyn

`dict_xsyn` (Extended Synonym Dictionary) is an example of an add-on dictionary template for full-text search. This dictionary type replaces words with groups of their synonyms, and so makes it possible to search for a word using any of its synonyms.

### F.12.1. Configuration

A `dict_xsyn` dictionary accepts the following options:

- `matchorig` controls whether the original word is accepted by the dictionary. Default is `true`.
- `matchsynonyms` controls whether the synonyms are accepted by the dictionary. Default is `false`.
- `keeporig` controls whether the original word is included in the dictionary's output. Default is `true`.

- `keepsynonyms` controls whether the synonyms are included in the dictionary's output. Default is `true`.
- `rules` is the base name of the file containing the list of synonyms. This file must be stored in `$$SHAREDIR/tsearch_data/` (where `$$SHAREDIR` means the Postgres Pro installation's shared-data directory). Its name must end in `.rules` (which is not to be included in the `rules` parameter).

The rules file has the following format:

- Each line represents a group of synonyms for a single word, which is given first on the line. Synonyms are separated by whitespace, thus:  

```
word syn1 syn2 syn3
```
- The sharp (`#`) sign is a comment delimiter. It may appear at any position in a line. The rest of the line will be skipped.

Look at `xsyn_sample.rules`, which is installed in `$$SHAREDIR/tsearch_data/`, for an example.

## F.12.2. Usage

Installing the `dict_xsyn` extension creates a text search template `xsyn_template` and a dictionary `xsyn` based on it, with default parameters. You can alter the parameters, for example

```
mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=false);
ALTER TEXT SEARCH DICTIONARY
```

or create new dictionaries based on the template.

To test the dictionary, you can try

```
mydb=# SELECT ts_lexize('xsyn', 'word');
         ts_lexize
-----
 {syn1,syn2,syn3}
```

```
mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=true);
ALTER TEXT SEARCH DICTIONARY
```

```
mydb=# SELECT ts_lexize('xsyn', 'word');
         ts_lexize
-----
 {word,syn1,syn2,syn3}
```

```
mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=false,
MATCHSYNONYMS=true);
ALTER TEXT SEARCH DICTIONARY
```

```
mydb=# SELECT ts_lexize('xsyn', 'syn1');
         ts_lexize
-----
 {syn1,syn2,syn3}
```

```
mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=true,
MATCHORIG=false, KEEPSYNONYMS=false);
ALTER TEXT SEARCH DICTIONARY
```

```
mydb=# SELECT ts_lexize('xsyn', 'syn1');
         ts_lexize
-----
 {word}
```

Real-world usage will involve including it in a text search configuration as described in [Chapter 12](#). That might look like this:

```
ALTER TEXT SEARCH CONFIGURATION english
ALTER MAPPING FOR word, asciiword WITH xsyn, english_stem;
```

## F.13. dump\_stat

The `dump_stat` module provides functions that allow you to backup and recover the contents of the `pg_statistic` table. When performing a dump/restore, you can use `dump_stat` to migrate the original statistics to the new server instead of running the `ANALYZE` command for the whole database cluster, which can significantly reduce downtime for large databases. The `dump_statistic` function generates `INSERT` statements which can later be applied to a compatible database. To successfully restore statistical data, you must install the extension on both the original and the recipient servers since these statements rely on the provided `dump_stat` functions.

Note that the definition of the `pg_statistic` table might change occasionally, which means that generated dump might be incompatible with future releases of Postgres Pro.

### F.13.1. Installation

The `dump_stat` extension is included into Postgres Pro. Once you have Postgres Pro installed, you must execute the `CREATE EXTENSION` command to enable `dump_stat`, as follows:

```
CREATE EXTENSION dump_stat;
```

### F.13.2. Functions

`anyarray_to_text(array anyarray)` returns text

Returns the given array as text.

`dump_statistic()` returns setof text

`dump_statistic` dumps the contents of the `pg_statistic` system catalog. It produces an `INSERT` statement per each tuple of the `pg_statistic`, excluding the ones that contain statistical data for tables in the `information_schema` and `pg_catalog` schemas.

The `INSERT` statement takes form of

```
WITH upsert as (
  UPDATE pg_catalog.pg_statistic SET column_name = expression [, ...]
  WHERE starelid = t_relname::regclass
  AND to_attnum(t_relname, staattnum) = t_attnum
  AND to_atttype(t_relname, staattnum) = t_atttype
  AND stainherit = t_stainherit
  RETURNING *)
ins as (
  SELECT expression [, ...]
  WHERE NOT EXISTS (SELECT * FROM upsert)
  AND to_attnum(t_relname, t_attnum) IS NOT NULL
  AND to_atttype(t_relname, t_attnum) = t_atttype)
INSERT INTO pg_catalog.pg_statistic SELECT * FROM ins;
```

where `expression` can be one of:

```
array_in(array_text, type_name::regtype::oid, -1)
value::type_name
```

To save the produced statements, redirect the `psql` output into a file using standard `psql` options. For details on the available `psql` options, see [psql](#). Meta-commands starting with a backslash are not supported.

For example, to save statistics for the `dbname` database into a `dump_stat.sql` file, run:

```
$ psql -XAtq -c "SELECT dump_statistic()" dbname > dump_stat.sql
```

`dump_statistic(schema_name text)` returns setof text

`dump_statistic` dumps the contents of the `pg_statistic` system catalog. It produces an INSERT statement per each tuple of the `pg_statistic` that relates to some table in the `schema_name` schema.

`dump_statistic(schema_name text, table_name text)` returns setof text

`dump_statistic` dumps the contents of the `pg_statistic` system catalog. It produces an INSERT statement per each tuple of the `pg_statistic` that relates to the specified `schema_name.table_name` table.

`dump_statistic(relation regclass)` returns setof text

`dump_statistic` dumps the contents of the `pg_statistic` system catalog. It produces an INSERT statement per each tuple of the `pg_statistic` that contains statistical data for the specified relation.

`to_schema_qualified_operator(opid oid)` returns text

Fetches the schema-qualified operator name by operator id `opid`. For example:

```
test=# SELECT to_schema_qualified_operator('+(int,int)::regoperator);
           to_schema_qualified_operator
-----
pg_catalog.+(pg_catalog.int4, pg_catalog.int4)
(1 row)
```

`to_schema_qualified_type(typid oid)` returns text

Fetches the schema-qualified type name by type id `typid`.

`to_schema_qualified_relation(relid oid)` returns text

Fetches the schema-qualified relation name by relation id `relid`.

`anyarray_elemtypename(arr anyarray)` returns oid

Returns the element type of the given array as `oid`. For example:

```
test=# SELECT anyarray_elemtypename(array_in('{1,2,3}', 'int)::regtype, -1));
           anyarray_elemtypename
-----
                               23
(1 row)
```

`to_attnname(relation regclass, colnum int2)` returns text

Given a relation name `relation` and a column number `colnum`, returns the column name as `text`.

`to_attnum(relation regclass, col text)` returns int2

Given a relation name `relation` and a column name `col`, returns the column number as `int2`.

`to_atttype(relation regclass, col text)` returns text

Given a relation name `relation` and a column name `col`, returns the schema-qualified column type as `text`.

`to_atttype(relation regclass, colnum int2)` returns text

Given a relation name `relation` and a column number `colnum`, returns the schema-qualified column type as `text`.

`to_namespace(nsp text)` returns oid

`to_namespace` duplicates the behavior of the cast to the `regnamespace` type, which is not present in the PostgreSQL 9.4 release (and prior releases). This function returns the `oid` of the given schema.

`get_namespace(relation oid)` returns `oid`

`get_namespace` returns the schema of the given relation as `oid`.

## F.14. earthdistance

The `earthdistance` module provides two different approaches to calculating great circle distances on the surface of the Earth. The one described first depends on the `cube` module. The second one is based on the built-in `point` data type, using longitude and latitude for the coordinates.

In this module, the Earth is assumed to be perfectly spherical. (If that's too inaccurate for you, you might want to look at the [PostGIS](#) project.)

The `cube` module must be installed before `earthdistance` can be installed (although you can use the `CASCADE` option of `CREATE EXTENSION` to install both in one command).

### Caution

It is strongly recommended that `earthdistance` and `cube` be installed in the same schema, and that that schema be one for which `CREATE` privilege has not been and will not be granted to any untrusted users. Otherwise there are installation-time security hazards if `earthdistance`'s schema contains objects defined by a hostile user. Furthermore, when using `earthdistance`'s functions after installation, the entire search path should contain only trusted schemas.

### F.14.1. Cube-Based Earth Distances

Data is stored in cubes that are points (both corners are the same) using 3 coordinates representing the `x`, `y`, and `z` distance from the center of the Earth. A domain `earth` over `cube` is provided, which includes constraint checks that the value meets these restrictions and is reasonably close to the actual surface of the Earth.

The radius of the Earth is obtained from the `earth()` function. It is given in meters. But by changing this one function you can change the module to use some other units, or to use a different value of the radius that you feel is more appropriate.

This package has applications to astronomical databases as well. Astronomers will probably want to change `earth()` to return a radius of `180/pi()` so that distances are in degrees.

Functions are provided to support input in latitude and longitude (in degrees), to support output of latitude and longitude, to calculate the great circle distance between two points and to easily specify a bounding box usable for index searches.

The provided functions are shown in [Table F.5](#).

**Table F.5. Cube-Based Earthdistance Functions**

Function	Description
<code>earth () → float8</code>	Returns the assumed radius of the Earth.
<code>sec_to_gc ( float8 ) → float8</code>	Converts the normal straight line (secant) distance between two points on the surface of the Earth to the great circle distance between them.
<code>gc_to_sec ( float8 ) → float8</code>	Converts the great circle distance between two points on the surface of the Earth to the normal straight line (secant) distance between them.
<code>ll_to_earth ( float8, float8 ) → earth</code>	

Function	Description
	Returns the location of a point on the surface of the Earth given its latitude (argument 1) and longitude (argument 2) in degrees.
<code>latitude ( earth ) → float8</code>	Returns the latitude in degrees of a point on the surface of the Earth.
<code>longitude ( earth ) → float8</code>	Returns the longitude in degrees of a point on the surface of the Earth.
<code>earth_distance ( earth, earth ) → float8</code>	Returns the great circle distance between two points on the surface of the Earth.
<code>earth_box ( earth, float8 ) → cube</code>	Returns a box suitable for an indexed search using the <code>cube @&gt;</code> operator for points within a given great circle distance of a location. Some points in this box are further than the specified great circle distance from the location, so a second check using <code>earth_distance</code> should be included in the query.

## F.14.2. Point-Based Earth Distances

The second part of the module relies on representing Earth locations as values of type `point`, in which the first component is taken to represent longitude in degrees, and the second component is taken to represent latitude in degrees. Points are taken as (longitude, latitude) and not vice versa because longitude is closer to the intuitive idea of x-axis and latitude to y-axis.

A single operator is provided, shown in [Table F.6](#).

**Table F.6. Point-Based Earthdistance Operators**

Operator	Description
<code>point &lt;@&gt; point → float8</code>	Computes the distance in statute miles between two points on the Earth's surface.

Note that unlike the `cube`-based part of the module, units are hardwired here: changing the `earth()` function will not affect the results of this operator.

One disadvantage of the longitude/latitude representation is that you need to be careful about the edge conditions near the poles and near +/- 180 degrees of longitude. The `cube`-based representation avoids these discontinuities.

## F.15. fasttrun

The `fasttrun` module provides transaction unsafe function to truncate temporary tables without growing `pg_class` size.

This module is required for 1C Enterprise support.

Fast truncate operation is not transactional, so its results cannot be rolled back and become immediately visible in all sessions regardless of isolation level.

### F.15.1. Function

There is a function call example:

```
select fasttruncate('TABLE_NAME');
```

### F.15.2. Test example

For tests you can use this example:

```
create or replace function f() returns void as $$
begin
  for i in 1..1000
  loop
    PERFORM fasttruncate('tt1');
  end loop;
end;
$$ language plpgsql;
```

### F.15.3. Authors

Teodor Sigaev <teodor@sigaev.ru>

## F.16. file\_fdw

The `file_fdw` module provides the foreign-data wrapper `file_fdw`, which can be used to access data files in the server's file system, or to execute programs on the server and read their output. The data file or program output must be in a format that can be read by `COPY FROM`; see [COPY](#) for details. Access to data files is currently read-only.

A foreign table created using this wrapper can have the following options:

`filename`

Specifies the file to be read. Relative paths are relative to the data directory. Either `filename` or `program` must be specified, but not both.

`program`

Specifies the command to be executed. The standard output of this command will be read as though `COPY FROM PROGRAM` were used. Either `program` or `filename` must be specified, but not both.

`format`

Specifies the data format, the same as `COPY`'s `FORMAT` option.

`header`

Specifies whether the data has a header line, the same as `COPY`'s `HEADER` option.

`delimiter`

Specifies the data delimiter character, the same as `COPY`'s `DELIMITER` option.

`quote`

Specifies the data quote character, the same as `COPY`'s `QUOTE` option.

`escape`

Specifies the data escape character, the same as `COPY`'s `ESCAPE` option.

`null`

Specifies the data null string, the same as `COPY`'s `NULL` option.

`encoding`

Specifies the data encoding, the same as `COPY`'s `ENCODING` option.

Note that while `COPY` allows options such as `HEADER` to be specified without a corresponding value, the foreign table option syntax requires a value to be present in all cases. To activate `COPY` options typically written without a value, you can pass the value `TRUE`, since all such options are Booleans.

A column of a foreign table created using this wrapper can have the following options:

`force_not_null`

This is a Boolean option. If true, it specifies that values of the column should not be matched against the null string (that is, the table-level `null` option). This has the same effect as listing the column in COPY's `FORCE_NOT_NULL` option.

`force_null`

This is a Boolean option. If true, it specifies that values of the column which match the null string are returned as `NULL` even if the value is quoted. Without this option, only unquoted values matching the null string are returned as `NULL`. This has the same effect as listing the column in COPY's `FORCE_NULL` option.

COPY's `FORCE_QUOTE` option is currently not supported by `file_fdw`.

These options can only be specified for a foreign table or its columns, not in the options of the `file_fdw` foreign-data wrapper, nor in the options of a server or user mapping using the wrapper.

Changing table-level options requires being a superuser or having the privileges of the default role `pg_read_server_files` (to use a filename) or the default role `pg_execute_server_program` (to use a program), for security reasons: only certain users should be able to control which file is read or which program is run. In principle regular users could be allowed to change the other options, but that's not supported at present.

When specifying the `program` option, keep in mind that the option string is executed by the shell. If you need to pass any arguments to the command that come from an untrusted source, you must be careful to strip or escape any characters that might have special meaning to the shell. For security reasons, it is best to use a fixed command string, or at least avoid passing any user input in it.

For a foreign table using `file_fdw`, `EXPLAIN` shows the name of the file to be read or program to be run. For a file, unless `COSTS OFF` is specified, the file size (in bytes) is shown as well.

### **Example F.1. Create a Foreign Table for Postgres Pro CSV Logs**

One of the obvious uses for `file_fdw` is to make the Postgres Pro activity log available as a table for querying. To do this, first you must be [logging to a CSV file](#), which here we will call `pglog.csv`. First, install `file_fdw` as an extension:

```
CREATE EXTENSION file_fdw;
```

Then create a foreign server:

```
CREATE SERVER pglog FOREIGN DATA WRAPPER file_fdw;
```

Now you are ready to create the foreign data table. Using the `CREATE FOREIGN TABLE` command, you will need to define the columns for the table, the CSV file name, and its format:

```
CREATE FOREIGN TABLE pglog (  
    log_time timestamp(3) with time zone,  
    user_name text,  
    database_name text,  
    process_id integer,  
    connection_from text,  
    session_id text,  
    session_line_num bigint,  
    command_tag text,  
    session_start_time timestamp with time zone,  
    virtual_transaction_id text,  
    transaction_id bigint,  
    error_severity text,  
    sql_state_code text,  
    message text,  
    detail text,
```

```
hint text,  
internal_query text,  
internal_query_pos integer,  
context text,  
query text,  
query_pos integer,  
location text,  
application_name text,  
backend_type text  
) SERVER pglog  
OPTIONS ( filename 'log/pglog.csv', format 'csv' );
```

That's it — now you can query your log directly. In production, of course, you would need to define some way to deal with log rotation.

## F.17. fulleq

The `fulleq` module provides additional equivalence operator for compatibility with Microsoft SQL Server.

This module is required for 1C Enterprise support.

### F.17.1. Overview

The Postgres Pro equivalence operator is defined to return NULL when both operands are NULLs. However, the Microsoft SQL Servers family traditionally defines other semantic for equivalence operator, where operator returns TRUE in the case of both nulled operands. This module provides such operator with MS SQL semantic.

### F.17.2. Operator `fulleq`

The `==` operator is defined for the following data types:

- `bool`
- `bytea`
- `char`
- `name`
- `int2`
- `int4`
- `int8`
- `int2vector`
- `text`
- `oid`
- `xid`
- `cid`
- `oidvector`
- `float4`
- `float8`
- `abstime`
- `reltime`
- `macaddr`
- `inet`
- `cidr`

- varchar
- date
- time
- timestamp
- timestamptz
- interval
- timetz

### F.17.3. Authors

Teodor Sigaev <teodor@sigae.ru>

## F.18. fuzzystmatch

The `fuzzystmatch` module provides several functions to determine similarities and distance between strings.

### Caution

At present, the `soundex`, `metaphone`, `dmetaphone`, and `dmetaphone_alt` functions do not work well with multibyte encodings (such as UTF-8).

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.18.1. Soundex

The Soundex system is a method of matching similar-sounding names by converting them to the same code. It was initially used by the United States Census in 1880, 1900, and 1910. Note that Soundex is not very useful for non-English names.

The `fuzzystmatch` module provides two functions for working with Soundex codes:

```
soundex(text) returns text
difference(text, text) returns int
```

The `soundex` function converts a string to its Soundex code. The `difference` function converts two strings to their Soundex codes and then reports the number of matching code positions. Since Soundex codes have four characters, the result ranges from zero to four, with zero being no match and four being an exact match. (Thus, the function is misnamed — *similarity* would have been a better name.)

Here are some usage examples:

```
SELECT soundex('hello world!');

SELECT soundex('Anne'), soundex('Ann'), difference('Anne', 'Ann');
SELECT soundex('Anne'), soundex('Andrew'), difference('Anne', 'Andrew');
SELECT soundex('Anne'), soundex('Margaret'), difference('Anne', 'Margaret');

CREATE TABLE s (nm text);

INSERT INTO s VALUES ('john');
INSERT INTO s VALUES ('joan');
INSERT INTO s VALUES ('wobbly');
INSERT INTO s VALUES ('jack');
```

```
SELECT * FROM s WHERE soundex(nm) = soundex('john');
```

```
SELECT * FROM s WHERE difference(s.nm, 'john') > 2;
```

## F.18.2. Levenshtein

This function calculates the Levenshtein distance between two strings:

```
levenshtein(text source, text target, int ins_cost, int del_cost, int sub_cost) returns  
int
```

```
levenshtein(text source, text target) returns int
```

```
levenshtein_less_equal(text source, text target, int ins_cost, int del_cost, int  
sub_cost, int max_d) returns int
```

```
levenshtein_less_equal(text source, text target, int max_d) returns int
```

Both `source` and `target` can be any non-null string, with a maximum of 255 characters. The cost parameters specify how much to charge for a character insertion, deletion, or substitution, respectively. You can omit the cost parameters, as in the second version of the function; in that case they all default to 1.

`levenshtein_less_equal` is an accelerated version of the Levenshtein function for use when only small distances are of interest. If the actual distance is less than or equal to `max_d`, then `levenshtein_less_equal` returns the correct distance; otherwise it returns some value greater than `max_d`. If `max_d` is negative then the behavior is the same as `levenshtein`.

Examples:

```
test=# SELECT levenshtein('GUMBO', 'GAMBOL');
```

```
levenshtein  
-----  
                2  
(1 row)
```

```
test=# SELECT levenshtein('GUMBO', 'GAMBOL', 2, 1, 1);
```

```
levenshtein  
-----  
                3  
(1 row)
```

```
test=# SELECT levenshtein_less_equal('extensive', 'exhaustive', 2);
```

```
levenshtein_less_equal  
-----  
                3  
(1 row)
```

```
test=# SELECT levenshtein_less_equal('extensive', 'exhaustive', 4);
```

```
levenshtein_less_equal  
-----  
                4  
(1 row)
```

## F.18.3. Metaphone

Metaphone, like Soundex, is based on the idea of constructing a representative code for an input string. Two strings are then deemed similar if they have the same codes.

This function calculates the metaphone code of an input string:

```
metaphone(text source, int max_output_length) returns text
```

`source` has to be a non-null string with a maximum of 255 characters. `max_output_length` sets the maximum length of the output metaphone code; if longer, the output is truncated to this length.

Example:

```
test=# SELECT metaphone('GUMBO', 4);
 metaphone
-----
 KM
(1 row)
```

## F.18.4. Double Metaphone

The Double Metaphone system computes two “sounds like” strings for a given input string — a “primary” and an “alternate”. In most cases they are the same, but for non-English names especially they can be a bit different, depending on pronunciation. These functions compute the primary and alternate codes:

```
dmetaphone(text source) returns text
dmetaphone_alt(text source) returns text
```

There is no length limit on the input strings.

Example:

```
test=# SELECT dmetaphone('gumbo');
 dmetaphone
-----
 KMP
(1 row)
```

## F.19. hstore

This module implements the `hstore` data type for storing sets of key/value pairs within a single Postgres Pro value. This can be useful in various scenarios, such as rows with many attributes that are rarely examined, or semi-structured data. Keys and values are simply text strings.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.19.1. hstore External Representation

The text representation of an `hstore`, used for input and output, includes zero or more `key => value` pairs separated by commas. Some examples:

```
k => v
foo => bar, baz => whatever
"1-a" => "anything at all"
```

The order of the pairs is not significant (and may not be reproduced on output). Whitespace between pairs or around the `=>` sign is ignored. Double-quote keys and values that include whitespace, commas, `=s` or `>s`. To include a double quote or a backslash in a key or value, escape it with a backslash.

Each key in an `hstore` is unique. If you declare an `hstore` with duplicate keys, only one will be stored in the `hstore` and there is no guarantee as to which will be kept:

```
SELECT 'a=>1,a=>2'::hstore;
 hstore
-----
 "a"=>"1"
```

A value (but not a key) can be an SQL `NULL`. For example:

```
key => NULL
```

The `NULL` keyword is case-insensitive. Double-quote the `NULL` to treat it as the ordinary string “NULL”.

**Note**

Keep in mind that the `hstore` text format, when used for input, applies *before* any required quoting or escaping. If you are passing an `hstore` literal via a parameter, then no additional processing is needed. But if you're passing it as a quoted literal constant, then any single-quote characters and (depending on the setting of the `standard_conforming_strings` configuration parameter) backslash characters need to be escaped correctly. See [Section 4.1.2.1](#) for more on the handling of string constants.

On output, double quotes always surround keys and values, even when it's not strictly necessary.

**F.19.2. hstore Operators and Functions**

The operators provided by the `hstore` module are shown in [Table F.7](#), the functions in [Table F.8](#).

**Table F.7. hstore Operators**

<b>Operator</b>	<b>Description</b>	<b>Example(s)</b>
<code>hstore -&gt; text → text</code>	Returns value associated with given key, or NULL if not present.	<code>'a=&gt;x, b=&gt;y'::hstore -&gt; 'a' → x</code>
<code>hstore -&gt; text [] → text []</code>	Returns values associated with given keys, or NULL if not present.	<code>'a=&gt;x, b=&gt;y, c=&gt;z'::hstore -&gt; ARRAY['c','a'] → {"z","x"}</code>
<code>hstore    hstore → hstore</code>	Concatenates two hstores.	<code>'a=&gt;b, c=&gt;d'::hstore    'c=&gt;x, d=&gt;q'::hstore → "a"=&gt;"b", "c"=&gt;"x", "d"=&gt;"q"</code>
<code>hstore ? text → boolean</code>	Does hstore contain key?	<code>'a=&gt;1'::hstore ? 'a' → t</code>
<code>hstore ?&amp; text [] → boolean</code>	Does hstore contain all the specified keys?	<code>'a=&gt;1,b=&gt;2'::hstore ?&amp; ARRAY['a','b'] → t</code>
<code>hstore ?  text [] → boolean</code>	Does hstore contain any of the specified keys?	<code>'a=&gt;1,b=&gt;2'::hstore ?  ARRAY['b','c'] → t</code>
<code>hstore @&gt; hstore → boolean</code>	Does left operand contain right?	<code>'a=&gt;b, b=&gt;1, c=&gt;NULL'::hstore @&gt; 'b=&gt;1' → t</code>
<code>hstore &lt;@ hstore → boolean</code>	Is left operand contained in right?	<code>'a=&gt;c'::hstore &lt;@ 'a=&gt;b, b=&gt;1, c=&gt;NULL' → f</code>
<code>hstore - text → hstore</code>	Deletes key from left operand.	<code>'a=&gt;1, b=&gt;2, c=&gt;3'::hstore - 'b'::text → "a"=&gt;"1", "c"=&gt;"3"</code>
<code>hstore - text [] → hstore</code>	Deletes keys from left operand.	

<b>Operator</b>	<b>Description</b>	<b>Example(s)</b>
		'a=>1, b=>2, c=>3'::hstore - ARRAY['a','b'] → "c"=>"3"
	hstore - hstore → hstore Deletes pairs from left operand that match pairs in the right operand.	'a=>1, b=>2, c=>3'::hstore - 'a=>4, b=>2'::hstore → "a"=>"1", "c"=>"3"
	anyelement #= hstore → anyelement Replaces fields in the left operand (which must be a composite type) with matching values from hstore.	ROW(1,3) #= 'f1=>11'::hstore → (11,3)
	%% hstore → text [] Converts hstore to an array of alternating keys and values.	%% 'a=>foo, b=>bar'::hstore → {a,foo,b,bar}
	%# hstore → text [] Converts hstore to a two-dimensional key/value array.	%# 'a=>foo, b=>bar'::hstore → {{a,foo},{b,bar}}

### Note

Prior to PostgreSQL 8.2, the containment operators @> and <@ were called @ and ~, respectively. These names are still available, but are deprecated and will eventually be removed. Notice that the old names are reversed from the convention formerly followed by the core geometric data types!

**Table F.8. hstore Functions**

<b>Function</b>	<b>Description</b>	<b>Example(s)</b>
hstore ( record ) → hstore	Constructs an hstore from a record or row.	hstore(ROW(1,2)) → "f1"=>"1", "f2"=>"2"
hstore ( text [] ) → hstore	Constructs an hstore from an array, which may be either a key/value array, or a two-dimensional array.	hstore(ARRAY['a','1','b','2']) → "a"=>"1", "b"=>"2" hstore(ARRAY[['c','3'],['d','4']]) → "c"=>"3", "d"=>"4"
hstore ( text [], text [] ) → hstore	Constructs an hstore from separate key and value arrays.	hstore(ARRAY['a','b'], ARRAY['1','2']) → "a"=>"1", "b"=>"2"
hstore ( text, text ) → hstore	Makes a single-item hstore.	hstore('a', 'b') → "a"=>"b"
akeys ( hstore ) → text []	Extracts an hstore's keys as an array.	akeys('a=>1,b=>2') → {a,b}
skeys ( hstore ) → setof text	Extracts an hstore's keys as a set.	

<b>Function</b>	<b>Description</b>	<b>Example(s)</b>
		<pre>skeys('a=&gt;1,b=&gt;2') → a b</pre>
	<p><code>avals ( hstore ) → text []</code>  <b>Extracts an hstore's values as an array.</b></p>	<pre>avals('a=&gt;1,b=&gt;2') → {1,2}</pre>
	<p><code>svals ( hstore ) → setof text</code>  <b>Extracts an hstore's values as a set.</b></p>	<pre>svals('a=&gt;1,b=&gt;2') → 1 2</pre>
	<p><code>hstore_to_array ( hstore ) → text []</code>  <b>Extracts an hstore's keys and values as an array of alternating keys and values.</b></p>	<pre>hstore_to_array('a=&gt;1,b=&gt;2') → {a,1,b,2}</pre>
	<p><code>hstore_to_matrix ( hstore ) → text []</code>  <b>Extracts an hstore's keys and values as a two-dimensional array.</b></p>	<pre>hstore_to_matrix('a=&gt;1,b=&gt;2') → {{a,1},{b,2}}</pre>
	<p><code>hstore_to_json ( hstore ) → json</code>  <b>Converts an hstore to a json value, converting all non-null values to JSON strings.</b>  <b>This function is used implicitly when an hstore value is cast to json.</b></p>	<pre>hstore_to_json('"a key"=&gt;1, b=&gt;t, c=&gt;null, d=&gt;12345, e=&gt;012345, f=&gt;1.234, g=&gt;2.345e+4') → {"a key": "1", "b": "t", "c": null, "d": "12345", "e": "012345", "f": "1.234", "g": "2.345e+4"}</pre>
	<p><code>hstore_to_jsonb ( hstore ) → jsonb</code>  <b>Converts an hstore to a jsonb value, converting all non-null values to JSON strings.</b>  <b>This function is used implicitly when an hstore value is cast to jsonb.</b></p>	<pre>hstore_to_jsonb('"a key"=&gt;1, b=&gt;t, c=&gt;null, d=&gt;12345, e=&gt;012345, f=&gt;1.234, g=&gt;2.345e+4') → {"a key": "1", "b": "t", "c": null, "d": "12345", "e": "012345", "f": "1.234", "g": "2.345e+4"}</pre>
	<p><code>hstore_to_json_loose ( hstore ) → json</code>  <b>Converts an hstore to a json value, but attempts to distinguish numerical and Boolean values so they are unquoted in the JSON.</b></p>	<pre>hstore_to_json_loose('"a key"=&gt;1, b=&gt;t, c=&gt;null, d=&gt;12345, e=&gt;012345, f=&gt;1.234, g=&gt;2.345e+4') → {"a key": 1, "b": true, "c": null, "d": 12345, "e": "012345", "f": 1.234, "g": 2.345e+4}</pre>
	<p><code>hstore_to_jsonb_loose ( hstore ) → jsonb</code>  <b>Converts an hstore to a jsonb value, but attempts to distinguish numerical and Boolean values so they are unquoted in the JSON.</b></p>	<pre>hstore_to_jsonb_loose('"a key"=&gt;1, b=&gt;t, c=&gt;null, d=&gt;12345, e=&gt;012345, f=&gt;1.234, g=&gt;2.345e+4') → {"a key": 1, "b": true, "c": null, "d": 12345, "e": "012345", "f": 1.234, "g": 2.345e+4}</pre>
	<p><code>slice ( hstore, text [] ) → hstore</code>  <b>Extracts a subset of an hstore containing only the specified keys.</b></p>	<pre>slice('a=&gt;1,b=&gt;2,c=&gt;3'::hstore, ARRAY['b','c','x']) → "b"=&gt;"2", "c"=&gt;"3"</pre>

<b>Function</b>	<b>Description</b>	<b>Example(s)</b>
<code>each ( hstore )</code>	<code>→ setof record ( key text, value text )</code> Extracts an hstore's keys and values as a set of records.	<pre>select * from each('a=&gt;1,b=&gt;2') →  key   value ----+----- a     1 b     2</pre>
<code>exist ( hstore, text )</code>	<code>→ boolean</code> Does hstore contain key?	<pre>exist('a=&gt;1', 'a') → t</pre>
<code>defined ( hstore, text )</code>	<code>→ boolean</code> Does hstore contain a non-NULL value for key?	<pre>defined('a=&gt;NULL', 'a') → f</pre>
<code>delete ( hstore, text )</code>	<code>→ hstore</code> Deletes pair with matching key.	<pre>delete('a=&gt;1,b=&gt;2', 'b') → "a"=&gt;"1"</pre>
<code>delete ( hstore, text [] )</code>	<code>→ hstore</code> Deletes pairs with matching keys.	<pre>delete('a=&gt;1,b=&gt;2,c=&gt;3', ARRAY['a','b']) → "c"=&gt;"3"</pre>
<code>delete ( hstore, hstore )</code>	<code>→ hstore</code> Deletes pairs matching those in the second argument.	<pre>delete('a=&gt;1,b=&gt;2', 'a=&gt;4,b=&gt;2'::hstore) → "a"=&gt;"1"</pre>
<code>populate_record ( anyelement, hstore )</code>	<code>→ anyelement</code> Replaces fields in the left operand (which must be a composite type) with matching values from hstore.	<pre>populate_record(ROW(1,2), 'f1=&gt;42'::hstore) → (42,2)</pre>

### F.19.3. Indexes

hstore has GiST and GIN index support for the @>, ?, ?& and ?| operators. For example:

```
CREATE INDEX hidx ON testhstore USING GIST (h);
```

```
CREATE INDEX hidx ON testhstore USING GIN (h);
```

`gist_hstore_ops` GiST opclass approximates a set of key/value pairs as a bitmap signature. Its optional integer parameter `siglen` determines the signature length in bytes. The default length is 16 bytes. Valid values of signature length are between 1 and 2024 bytes. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

Example of creating such an index with a signature length of 32 bytes:

```
CREATE INDEX hidx ON testhstore USING GIST (h gist_hstore_ops(siglen=32));
```

hstore also supports btree or hash indexes for the = operator. This allows hstore columns to be declared UNIQUE, or to be used in GROUP BY, ORDER BY or DISTINCT expressions. The sort ordering for hstore values is not particularly useful, but these indexes may be useful for equivalence lookups. Create indexes for = comparisons as follows:

```
CREATE INDEX hidx ON testhstore USING BTREE (h);
```

```
CREATE INDEX hidx ON testhstore USING HASH (h);
```

## F.19.4. Examples

Add a key, or update an existing key with a new value:

```
UPDATE tab SET h = h || hstore('c', '3');
```

Delete a key:

```
UPDATE tab SET h = delete(h, 'k1');
```

Convert a record to an hstore:

```
CREATE TABLE test (col1 integer, col2 text, col3 text);
INSERT INTO test VALUES (123, 'foo', 'bar');
```

```
SELECT hstore(t) FROM test AS t;
           hstore
```

```
-----
"col1"=>"123", "col2"=>"foo", "col3"=>"bar"
(1 row)
```

Convert an hstore to a predefined record type:

```
CREATE TABLE test (col1 integer, col2 text, col3 text);
```

```
SELECT * FROM populate_record(null::test,
                               "col1"=>"456", "col2"=>"zzz");
```

```
col1 | col2 | col3
-----+-----+-----
 456 | zzz  |
(1 row)
```

Modify an existing record using the values from an hstore:

```
CREATE TABLE test (col1 integer, col2 text, col3 text);
INSERT INTO test VALUES (123, 'foo', 'bar');
```

```
SELECT (r).* FROM (SELECT t #= '"col3"=>"baz"' AS r FROM test t) s;
col1 | col2 | col3
-----+-----+-----
 123 | foo  | baz
(1 row)
```

## F.19.5. Statistics

The `hstore` type, because of its intrinsic liberality, could contain a lot of different keys. Checking for valid keys is the task of the application. The following examples demonstrate several techniques for checking keys and obtaining statistics.

Simple example:

```
SELECT * FROM each('aaa=>bq, b=>NULL, ""=>1');
```

Using a table:

```
SELECT (each(h)).key, (each(h)).value INTO stat FROM testhstore;
```

Online statistics:

```
SELECT key, count(*) FROM
```

```
(SELECT (each(h)).key FROM testhstore) AS stat
GROUP BY key
ORDER BY count DESC, key;
```

key	count
line	883
query	207
pos	203
node	202
space	197
status	195
public	194
title	190
org	189

.....

### F.19.6. Compatibility

As of PostgreSQL 9.0, `hstore` uses a different internal representation than previous versions. This presents no obstacle for dump/restore upgrades since the text representation (used in the dump) is unchanged.

In the event of a binary upgrade, upward compatibility is maintained by having the new code recognize old-format data. This will entail a slight performance penalty when processing data that has not yet been modified by the new code. It is possible to force an upgrade of all values in a table column by doing an `UPDATE` statement as follows:

```
UPDATE tablename SET hstorecol = hstorecol || '';
```

Another way to do it is:

```
ALTER TABLE tablename ALTER hstorecol TYPE hstore USING hstorecol || '';
```

The `ALTER TABLE` method requires an `ACCESS EXCLUSIVE` lock on the table, but does not result in bloating the table with old row versions.

### F.19.7. Transforms

Additional extensions are available that implement transforms for the `hstore` type for the languages PL/Perl and PL/Python. The extensions for PL/Perl are called `hstore_plperl` and `hstore_plperlu`, for trusted and untrusted PL/Perl. If you install these transforms and specify them when creating a function, `hstore` values are mapped to Perl hashes. The extensions for PL/Python are called `hstore_plpythonu`, `hstore_plpython2u`, and `hstore_plpython3u` (see [Section 43.1](#) for the PL/Python naming convention). If you use them, `hstore` values are mapped to Python dictionaries.

#### Caution

It is strongly recommended that the transform extensions be installed in the same schema as `hstore`. Otherwise there are installation-time security hazards if a transform extension's schema contains objects defined by a hostile user.

### F.19.8. Authors

Oleg Bartunov <oleg@sai.msu.su>, Moscow, Moscow University, Russia

Teodor Sigaev <teodor@sigaev.ru>, Moscow, Delta-Soft Ltd., Russia

Additional enhancements by Andrew Gierth <andrew@tao11.riddles.org.uk>, United Kingdom

## F.20. Hunspell Dictionaries Modules

These modules provide Hunspell dictionaries for various languages. Upon installation of the module into database using `CREATE EXTENSION` command, text search dictionary and configuration objects in the public schema appear.

**Table F.9. Modules**

Language	Extension name	Dictionary name	Configuration name
American English	hunspell_en_us	english_hunspell	english_hunspell
Dutch	hunspell_nl_nl	dutch_hunspell	dutch_hunspell
French	hunspell_fr	french_hunspell	french_hunspell
Russian	hunspell_ru_ru	russian_hunspell	russian_hunspell

### F.20.1. Examples

Text search objects will be created after installation of a dictionary module. We can test created configuration:

```
SELECT * FROM ts_debug('english_hunspell', 'abilities');
  alias | description | token | dictionaries |
  dictionary | lexemes
-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----
  asciiword | Word, all ASCII | abilities | {english_hunspell,english_stem} |
  english_hunspell | {ability}
(1 row)
```

Or you can create your own text search configuration. For example, with the created dictionaries and with the Snowball dictionary you can create mixed russian-english configuration:

```
CREATE TEXT SEARCH CONFIGURATION russian_en (
  COPY = simple
);

ALTER TEXT SEARCH CONFIGURATION russian_en
  ALTER MAPPING FOR asciiword, asciihword, hword_asciipart
  WITH english_hunspell, english_stem;

ALTER TEXT SEARCH CONFIGURATION russian_en
  ALTER MAPPING FOR word, hword, hword_part
  WITH russian_hunspell, russian_stem;
```

You can create mixed dictionaries only for languages with different alphabets. If languages have similar alphabets then Postgres Pro can not decide which dictionary should be used.

A text search configuration which is created with a dictionary module is ready to use. For example, in this text you can search some words:

```
SELECT to_tsvector('english_hunspell', 'The blue whale is the largest animal');
  to_tsvector
-----
  'animal':7 'blue':2 'large':6 'whale':3
(1 row)
```

Search query might look like this:

```
SELECT to_tsvector('english_hunspell', 'The blue whale is the largest animal')
  @@ to_tsquery('english_hunspell', 'large & whale');
```

```
?column?  
-----  
t  
(1 row)
```

With this configurations you can search a text using GIN or GIST indexes. For example, there is a table with GIN index:

```
CREATE TABLE table1 (t varchar);  
INSERT INTO table1 VALUES ('The blue whale is the largest animal');  
CREATE INDEX t_idx ON table1 USING GIN (to_tsvector('english_hunspell', "t"));
```

For this table you can execute the following query:

```
SELECT * FROM table1 where to_tsvector('english_hunspell', t)  
    @@ to_tsquery('english_hunspell', 'blue & animal');  
           t  
-----  
The blue whale is the largest animal  
(1 row)
```

## F.21. intagg

The `intagg` module provides an integer aggregator and an enumerator. `intagg` is now obsolete, because there are built-in functions that provide a superset of its capabilities. However, the module is still provided as a compatibility wrapper around the built-in functions.

### F.21.1. Functions

The aggregator is an aggregate function `int_array_aggregate(integer)` that produces an integer array containing exactly the integers it is fed. This is a wrapper around `array_agg`, which does the same thing for any array type.

The enumerator is a function `int_array_enum(integer[])` that returns `setof integer`. It is essentially the reverse operation of the aggregator: given an array of integers, expand it into a set of rows. This is a wrapper around `unnest`, which does the same thing for any array type.

### F.21.2. Sample Uses

Many database systems have the notion of a one to many table. Such a table usually sits between two indexed tables, for example:

```
CREATE TABLE left (id INT PRIMARY KEY, ...);  
CREATE TABLE right (id INT PRIMARY KEY, ...);  
CREATE TABLE one_to_many(left INT REFERENCES left, right INT REFERENCES right);
```

It is typically used like this:

```
SELECT right.* from right JOIN one_to_many ON (right.id = one_to_many.right)  
    WHERE one_to_many.left = item;
```

This will return all the items in the right hand table for an entry in the left hand table. This is a very common construct in SQL.

Now, this methodology can be cumbersome with a very large number of entries in the `one_to_many` table. Often, a join like this would result in an index scan and a fetch for each right hand entry in the table for a particular left hand entry. If you have a very dynamic system, there is not much you can do. However, if you have some data which is fairly static, you can create a summary table with the aggregator.

```
CREATE TABLE summary AS  
    SELECT left, int_array_aggregate(right) AS right  
    FROM one_to_many
```

```
GROUP BY left;
```

This will create a table with one row per left item, and an array of right items. Now this is pretty useless without some way of using the array; that's why there is an array enumerator. You can do

```
SELECT left, int_array_enum(right) FROM summary WHERE left = item;
```

The above query using `int_array_enum` produces the same results as

```
SELECT left, right FROM one_to_many WHERE left = item;
```

The difference is that the query against the summary table has to get only one row from the table, whereas the direct query against `one_to_many` must index scan and fetch a row for each entry.

On one system, an `EXPLAIN` showed a query with a cost of 8488 was reduced to a cost of 329. The original query was a join involving the `one_to_many` table, which was replaced by:

```
SELECT right, count(right) FROM
  ( SELECT left, int_array_enum(right) AS right
    FROM summary JOIN (SELECT left FROM left_table WHERE left = item) AS lefts
    ON (summary.left = lefts.left)
  ) AS list
GROUP BY right
ORDER BY count DESC;
```

## F.22. intarray

The `intarray` module provides a number of useful functions and operators for manipulating null-free arrays of integers. There is also support for indexed searches using some of the operators.

All of these operations will throw an error if a supplied array contains any `NULL` elements.

Many of these operations are only sensible for one-dimensional arrays. Although they will accept input arrays of more dimensions, the data is treated as though it were a linear array in storage order.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.22.1. intarray Functions and Operators

The functions provided by the `intarray` module are shown in [Table F.10](#), the operators in [Table F.11](#).

**Table F.10. intarray Functions**

Function	Description	Example(s)
<code>icount ( integer[] )</code>	<code>→ integer</code> Returns the number of elements in the array.	<code>icount ('{1,2,3}'::integer[]) → 3</code>
<code>sort ( integer[], dir text )</code>	<code>→ integer[]</code> Sorts the array in either ascending or descending order. <i>dir</i> must be <code>asc</code> or <code>desc</code> .	<code>sort ('{1,3,2}'::integer[], 'desc') → {3,2,1}</code>
<code>sort ( integer[] )</code>	<code>→ integer[]</code>	
<code>sort_asc ( integer[] )</code>	<code>→ integer[]</code> Sorts in ascending order.	<code>sort(array[11,77,44]) → {11,44,77}</code>
<code>sort_desc ( integer[] )</code>	<code>→ integer[]</code> Sorts in descending order.	

<b>Function</b>	<b>Description</b>	<b>Example(s)</b>
<code>sort_desc(array[11, 77, 44])</code>		<code>→ {77, 44, 11}</code>
<code>uniq ( integer[] )</code>	<code>→ integer[]</code> Removes adjacent duplicates.	
<code>uniq(sort ('{1,2,3,2,1}'::integer[]))</code>		<code>→ {1, 2, 3}</code>
<code>idx ( integer[], item integer )</code>	<code>→ integer</code> Returns index of the first array element matching <i>item</i> , or 0 if no match.	
<code>idx(array[11, 22, 33, 22, 11], 22)</code>		<code>→ 2</code>
<code>subarray ( integer[], start integer, len integer )</code>	<code>→ integer[]</code> Extracts the portion of the array starting at position <i>start</i> , with <i>len</i> elements.	
<code>subarray ('{1,2,3,2,1}'::integer[], 2, 3)</code>		<code>→ {2, 3, 2}</code>
<code>subarray ( integer[], start integer )</code>	<code>→ integer[]</code> Extracts the portion of the array starting at position <i>start</i> .	
<code>subarray ('{1,2,3,2,1}'::integer[], 2)</code>		<code>→ {2, 3, 2, 1}</code>
<code>intset ( integer )</code>	<code>→ integer[]</code> Makes a single-element array.	
<code>intset (42)</code>		<code>→ {42}</code>

**Table F.11. intarray Operators**

<b>Operator</b>	<b>Description</b>
<code>integer[] &amp;&amp; integer[]</code>	<code>→ boolean</code> Do arrays overlap (have at least one element in common)?
<code>integer[] @&gt; integer[]</code>	<code>→ boolean</code> Does left array contain right array?
<code>integer[] &lt;@ integer[]</code>	<code>→ boolean</code> Is left array contained in right array?
<code># integer[]</code>	<code>→ integer</code> Returns the number of elements in the array.
<code>integer[] # integer</code>	<code>→ integer</code> Returns index of the first array element matching the right argument, or 0 if no match. (Same as <code>idx</code> function.)
<code>integer[] + integer</code>	<code>→ integer[]</code> Adds element to end of array.
<code>integer[] + integer[]</code>	<code>→ integer[]</code> Concatenates the arrays.
<code>integer[] - integer</code>	<code>→ integer[]</code> Removes entries matching the right argument from the array.
<code>integer[] - integer[]</code>	<code>→ integer[]</code> Removes elements of the right array from the left array.
<code>integer[]   integer</code>	<code>→ integer[]</code> Computes the union of the arguments.
<code>integer[]   integer[]</code>	<code>→ integer[]</code>

Operator	Description
	Computes the union of the arguments.
<code>integer[] &amp; integer[] → integer[]</code>	Computes the intersection of the arguments.
<code>integer[] @@ query_int → boolean</code>	Does array satisfy query? (see below)
<code>query_int ~~ integer[] → boolean</code>	Does array satisfy query? (commutator of @@)

(Before PostgreSQL 8.2, the containment operators `@>` and `<@` were respectively called `@` and `~`. These names are still available, but are deprecated and will eventually be retired. Notice that the old names are reversed from the convention formerly followed by the core geometric data types!)

The operators `&&`, `@>` and `<@` are equivalent to Postgres Pro's built-in operators of the same names, except that they work only on integer arrays that do not contain nulls, while the built-in operators work for any array type. This restriction makes them faster than the built-in operators in many cases.

The `@@` and `~~` operators test whether an array satisfies a *query*, which is expressed as a value of a specialized data type `query_int`. A *query* consists of integer values that are checked against the elements of the array, possibly combined using the operators `&` (AND), `|` (OR), and `!` (NOT). Parentheses can be used as needed. For example, the query `1&(2|3)` matches arrays that contain 1 and also contain either 2 or 3.

## F.22.2. Index Support

`intarray` provides index support for the `&&`, `@>`, `<@`, and `@@` operators, as well as regular array equality.

Two parameterized GiST index operator classes are provided: `gist__int_ops` (used by default) is suitable for small- to medium-size data sets, while `gist__intbig_ops` uses a larger signature and is more suitable for indexing large data sets (i.e., columns containing a large number of distinct array values). The implementation uses an RD-tree data structure with built-in lossy compression.

`gist__int_ops` approximates an integer set as an array of integer ranges. Its optional integer parameter `numranges` determines the maximum number of ranges in one index key. The default value of `numranges` is 100. Valid values are between 1 and 253. Using larger arrays as GiST index keys leads to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

`gist__intbig_ops` approximates an integer set as a bitmap signature. Its optional integer parameter `siglen` determines the signature length in bytes. The default signature length is 16 bytes. Valid values of signature length are between 1 and 2024 bytes. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

There is also a non-default GIN operator class `gin__int_ops` supporting the same operators.

The choice between GiST and GIN indexing depends on the relative performance characteristics of GiST and GIN, which are discussed elsewhere.

## F.22.3. Example

```
-- a message can be in one or more "sections"
CREATE TABLE message (mid INT PRIMARY KEY, sections INT[], ...);

-- create specialized index with signature length of 32 bytes
CREATE INDEX message_rdtree_idx ON message USING GIST (sections gist__intbig_ops
(siglen = 32));
```

```
-- select messages in section 1 OR 2 - OVERLAP operator
SELECT message.mid FROM message WHERE message.sections && '{1,2}';

-- select messages in sections 1 AND 2 - CONTAINS operator
SELECT message.mid FROM message WHERE message.sections @> '{1,2}';

-- the same, using QUERY operator
SELECT message.mid FROM message WHERE message.sections @@ '1&2'::query_int;
```

## F.22.4. Authors

All work was done by Teodor Sigaev (<teodor@sigaev.ru>) and Oleg Bartunov (<oleg@sai.msu.su>). See <http://www.sai.msu.su/~megera/postgres/gist/> for additional information. Andrey Oktyabrski did a great work on adding new functions and operations.

## F.23. isn

The `isn` module provides data types for the following international product numbering standards: EAN13, UPC, ISBN (books), ISMN (music), and ISSN (serials). Numbers are validated on input according to a hard-coded list of prefixes; this list of prefixes is also used to hyphenate numbers on output. Since new prefixes are assigned from time to time, the list of prefixes may be out of date. It is hoped that a future version of this module will obtain the prefix list from one or more tables that can be easily updated by users as needed; however, at present, the list can only be updated by modifying the source code and recompiling. Alternatively, prefix validation and hyphenation support may be dropped from a future version of this module.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.23.1. Data Types

Table F.12 shows the data types provided by the `isn` module.

**Table F.12. isn Data Types**

Data Type	Description
EAN13	European Article Numbers, always displayed in the EAN13 display format
ISBN13	International Standard Book Numbers to be displayed in the new EAN13 display format
ISMN13	International Standard Music Numbers to be displayed in the new EAN13 display format
ISSN13	International Standard Serial Numbers to be displayed in the new EAN13 display format
ISBN	International Standard Book Numbers to be displayed in the old short display format
ISMN	International Standard Music Numbers to be displayed in the old short display format
ISSN	International Standard Serial Numbers to be displayed in the old short display format
UPC	Universal Product Codes

Some notes:

1. ISBN13, ISMN13, ISSN13 numbers are all EAN13 numbers.
2. EAN13 numbers aren't always ISBN13, ISMN13 or ISSN13 (some are).

3. Some ISBN13 numbers can be displayed as ISBN.
4. Some ISMN13 numbers can be displayed as ISMN.
5. Some ISSN13 numbers can be displayed as ISSN.
6. UPC numbers are a subset of the EAN13 numbers (they are basically EAN13 without the first 0 digit).
7. All UPC, ISBN, ISMN and ISSN numbers can be represented as EAN13 numbers.

Internally, all these types use the same representation (a 64-bit integer), and all are interchangeable. Multiple types are provided to control display formatting and to permit tighter validity checking of input that is supposed to denote one particular type of number.

The `ISBN`, `ISMN`, and `ISSN` types will display the short version of the number (ISxN 10) whenever it's possible, and will show ISxN 13 format for numbers that do not fit in the short version. The `EAN13`, `ISBN13`, `ISMN13` and `ISSN13` types will always display the long version of the ISxN (EAN13).

## F.23.2. Casts

The `isn` module provides the following pairs of type casts:

- ISBN13  $\Leftrightarrow$  EAN13
- ISMN13  $\Leftrightarrow$  EAN13
- ISSN13  $\Leftrightarrow$  EAN13
- ISBN  $\Leftrightarrow$  EAN13
- ISMN  $\Leftrightarrow$  EAN13
- ISSN  $\Leftrightarrow$  EAN13
- UPC  $\Leftrightarrow$  EAN13
- ISBN  $\Leftrightarrow$  ISBN13
- ISMN  $\Leftrightarrow$  ISMN13
- ISSN  $\Leftrightarrow$  ISSN13

When casting from `EAN13` to another type, there is a run-time check that the value is within the domain of the other type, and an error is thrown if not. The other casts are simply relabelings that will always succeed.

## F.23.3. Functions and Operators

The `isn` module provides the standard comparison operators, plus B-tree and hash indexing support for all these data types. In addition there are several specialized functions; shown in [Table F.13](#). In this table, `isn` means any one of the module's data types.

**Table F.13. `isn` Functions**

Function	Description
<code>isn_weak (boolean) → boolean</code>	Sets the weak input mode, and returns new setting.
<code>isn_weak () → boolean</code>	Returns the current status of the weak mode.
<code>make_valid (isn) → isn</code>	Validates an invalid number (clears the invalid flag).
<code>is_valid (isn) → boolean</code>	

Function	Description
	Checks for the presence of the invalid flag.

*Weak* mode is used to be able to insert invalid data into a table. Invalid means the check digit is wrong, not that there are missing numbers.

Why would you want to use the weak mode? Well, it could be that you have a huge collection of ISBN numbers, and that there are so many of them that for weird reasons some have the wrong check digit (perhaps the numbers were scanned from a printed list and the OCR got the numbers wrong, perhaps the numbers were manually captured... who knows). Anyway, the point is you might want to clean the mess up, but you still want to be able to have all the numbers in your database and maybe use an external tool to locate the invalid numbers in the database so you can verify the information and validate it more easily; so for example you'd want to select all the invalid numbers in the table.

When you insert invalid numbers in a table using the weak mode, the number will be inserted with the corrected check digit, but it will be displayed with an exclamation mark (!) at the end, for example 0-11-000322-5!. This invalid marker can be checked with the `is_valid` function and cleared with the `make_valid` function.

You can also force the insertion of invalid numbers even when not in the weak mode, by appending the `!` character at the end of the number.

Another special feature is that during input, you can write `?` in place of the check digit, and the correct check digit will be inserted automatically.

## F.23.4. Examples

```
--Using the types directly:
SELECT isbn('978-0-393-04002-9');
SELECT isbn13('0901690546');
SELECT issn('1436-4522');

--Casting types:
-- note that you can only cast from ean13 to another type when the
-- number would be valid in the realm of the target type;
-- thus, the following will NOT work: select isbn(ean13('0220356483481'));
-- but these will:
SELECT upc(ean13('0220356483481'));
SELECT ean13(upc('220356483481'));

--Create a table with a single column to hold ISBN numbers:
CREATE TABLE test (id isbn);
INSERT INTO test VALUES('9780393040029');

--Automatically calculate check digits (observe the '?'):
INSERT INTO test VALUES('220500896?');
INSERT INTO test VALUES('978055215372?');

SELECT issn('3251231?');
SELECT ismn('979047213542?');

--Using the weak mode:
SELECT isn_weak(true);
INSERT INTO test VALUES('978-0-11-000533-4');
INSERT INTO test VALUES('9780141219307');
INSERT INTO test VALUES('2-205-00876-X');
SELECT isn_weak(false);
```

```
SELECT id FROM test WHERE NOT is_valid(id);
UPDATE test SET id = make_valid(id) WHERE id = '2-205-00876-X!';

SELECT * FROM test;

SELECT isbn13(id) FROM test;
```

## F.23.5. Bibliography

The information to implement this module was collected from several sites, including:

- <https://www.isbn-international.org/>
- <https://www.issn.org/>
- <https://www.ismn-international.org/>
- <https://www.wikipedia.org/>

The prefixes used for hyphenation were also compiled from:

- <https://www.gs1.org/standards/id-keys>
- [https://en.wikipedia.org/wiki/List\\_of\\_ISBN\\_identifier\\_groups](https://en.wikipedia.org/wiki/List_of_ISBN_identifier_groups)
- <https://www.isbn-international.org/content/isbn-users-manual>
- [https://en.wikipedia.org/wiki/International\\_Standard\\_Music\\_Number](https://en.wikipedia.org/wiki/International_Standard_Music_Number)
- <https://www.ismn-international.org/ranges.html>

Care was taken during the creation of the algorithms and they were meticulously verified against the suggested algorithms in the official ISBN, ISMN, ISSN User Manuals.

## F.23.6. Author

Germán Méndez Bravo (Kronuz), 2004–2006

This module was inspired by Garrett A. Wollman's `isbn_issn` code.

## F.24. jquery

jQuery is a language to query `jsonb` data type. Its primary goal is to provide an additional functionality for `jsonb`, such as a simple and effective way for search in nested objects and arrays, as well as additional comparison operators with index support.

jQuery is implemented by means of a `jquery` data type (similar to `tsquery`) and the `@@` match operator for `jsonb`.

### F.24.1. Installation

Postgres Pro distribution includes `jquery` as a contrib module. Once you complete Postgres Pro Standard installation, create the `jquery` extension, as follows:

```
CREATE EXTENSION jquery;
```

### F.24.2. JSON query language

jQuery extension contains `jquery` datatype which represents whole JSON query as a single value (like `tsquery` does for fulltext search). The query is an expression on JSON-document values.

Simple expression is specified as *path binary\_operator value* or *path unary\_operator*. See the following examples.

- `x = "abc"` - value of key "x" is equal to "abc";

- `$ @> [4, 5, "zzz"]` - the JSON document is an array containing values 4, 5 and "zzz";
- `"abc xyz" >= 10` - value of key "abc xyz" is greater than or equal to 10;
- `volume IS NUMERIC` - type of key "volume" is numeric.
- `$ = true` - the whole JSON document is just a true.
- `similar_ids.@# > 5` - similar\_ids is an array or object of length greater than 5;
- `similar_product_ids.# = "0684824396"` - array similar\_product\_ids contains string "0684824396".
- `*.color = "red"` - there is object somewhere which key "color" has value "red".
- `foo = *` - key "foo" exists in object.

Path selects set of JSON values to be checked using given operators. In the simplest case, path is just a key name. In general, path is key names and placeholders combined by dot signs. Path can use the following placeholders:

- `#` - any index of array;
- `#N` - Nth index of array;
- `%` - any key of object;
- `*` - any sequence of array indexes and object keys;
- `@#` - length of array or object, could be only used as last component of path;
- `$` - the whole JSON document as single value, could be only the whole path.

Expression is true when operator is true against at least one value selected by path.

Key names could be given either with or without double quotes. Key names without double quotes shouldn't contain spaces, start with number, or concur with jquery keyword.

The supported binary operators are:

- Equality operator: `=`;
- Numeric comparison operators: `>`, `>=`, `<`, `<=`;
- Search in the list of scalar values using `IN` operator;
- Array comparison operators: `&&` (overlap), `@>` (contains), `<@` (contained in).
- Filtering operator: `~~`. Taking `jsonb` data as the left operand and a `jquery` expression as the right operand, this operator checks that `jsonb` data contains any entries that satisfy the condition provided in a `jquery` expression and returns an array of such entries, if any.

The supported unary operators are:

- Check for existence operator: `= *`;
- Check for type operators: `IS ARRAY`, `IS NUMERIC`, `IS OBJECT`, `IS STRING` and `IS BOOLEAN`.

Expressions could be complex. Complex expression is a set of expressions combined by logical operators (AND, OR, NOT) and grouped using parentheses.

Examples of complex expressions are given below.

- `a = 1 AND (b = 2 OR c = 3) AND NOT d = 1`
- `x.% = true OR x.# = true`

Prefix expressions are expressions given in the form `path (subexpression)`. In this case path selects JSON values to be checked using given subexpression. Check results are aggregated in the same way as in simple expressions.

- `#(a = 1 AND b = 2)` - an array contains an element where the `a` key is 1 and the `b` key is 2
- `%( $ >= 10 AND $ <= 20 )` - an object contains a key with a value between 10 and 20

Path also could contain the following special placeholders with "every" semantics:

- `#:` - every index of array;
- `%:` - every key of object;
- `*:` - every sequence of array indexes and object keys.

Consider the following example.

```
%.#:( $ >= 0 AND $ <= 1)
```

This example could be read as follows: there is at least one key for which the value is an array of numerics between 0 and 1.

We can rewrite this example in the following form with extra parentheses.

```
%(#:( $ >= 0 AND $ <= 1))
```

The first placeholder % checks that expression in parentheses is true for at least one value in object. The second placeholder #: checks that the value is an array and all its elements satisfy expressions in parentheses.

We can rewrite this example without #: placeholder as follows.

```
%(NOT #(NOT ( $ >= 0 AND $ <= 1)) AND $ IS ARRAY)
```

In this example we transform assertion that every element of array satisfies some condition to assertion that there is no one element which doesn't satisfy the same condition.

Some examples of using paths are given below.

- `numbers.#: IS NUMERIC` - every element of "numbers" array is numeric.
- `*:( $ IS OBJECT OR $ IS BOOLEAN)` - JSON is a structure of nested objects with booleans as leaf values.
- `#:.%:( $ >= 0 AND $ <= 1)` - each element of array is object containing only numeric values between 0 and 1.
- `documents.#:.% = *` - "documents" is an array of objects containing at least one key.
- `%.#: ( $ IS STRING)` - JSON object contains at least one array of strings.
- `#.% = true` - at least one array element is an object that contains at least one "true" value.

Usage of path operators and parentheses needs some explanation. When same path operators are used multiple times they may refer to different values while you can refer to the same value multiple times by using parentheses and \$ operator. See the following examples.

- `# < 10 AND # > 20` - there is an element less than 10 and another element greater than 20.
- `#( $ < 10 AND $ > 20)` - there is an element that is both less than 10 and greater than 20 (impossible).
- `#( $ >= 10 AND $ <= 20)` - there is an element between 10 and 20.
- `# >= 10 AND # <= 20` - there is an element greater than or equal to 10 and another element less than or equal to 20. The query can be satisfied by an array with no elements between 10 and 20, for instance [0,30].

Same rules apply when you search inside objects and branchy structures.

Type checking operators and "every" placeholders are useful for document schema validation. JQuery matching operator @@ is immutable and can be used in CHECK constraint. See the following example.

```
CREATE TABLE js (  
  id serial,  
  data jsonb,  
  CHECK (data @@ '  
    name IS STRING AND  
    similar_ids.#: IS NUMERIC AND  
    points.#:(x IS NUMERIC AND y IS NUMERIC) '::jsquery));
```

In this example check constraint validates that in "data" jsonb column: value of "name" key is string, value of "similar\_ids" key is array of numerics, value of "points" key is array of objects which contain numeric values in "x" and "y" keys.

See our [pgconf.eu presentation](http://pgconf.eu/presentation) for more examples.

### F.24.3. GIN indexes

jQuery extension contains two operator classes (opclasses) for GIN which provide different kinds of query optimization.

- `jsonb_path_value_ops`
- `jsonb_value_path_ops`

In each of two GIN opclasses `jsonb` documents are decomposed into entries. Each entry is associated with a particular value and its path. Difference between opclasses is in the entry representation, comparison, and usage for search optimization.

For example, `jsonb` document `{"a": [{"b": "xyz", "c": true}, 10], "d": {"e": [7, false]}}` would be decomposed into the following entries:

- `"a".#."b"."xyz"`
- `"a".#."c".true`
- `"a".#.10`
- `"d"."e".#.7`
- `"d"."e".#.false`

Since jQuery doesn't support search in a particular array index, we consider all array elements to be equivalent. Thus, each array element is marked with the same `#` sign in the path.

Major problem in the entries representation is its size. In the given example key `"a"` is presented three times. In the large branchy documents with long keys size of naive entries representation becomes unreasonable. Both opclasses address this issue but in a slightly different way.

#### F.24.3.1. `jsonb_path_value_ops`

`jsonb_path_value_ops` represents entry as pair of path hash and value. The following pseudocode illustrates it.

```
(hash(path_item_1.path_item_2. ... .path_item_n); value)
```

In comparison of entries path hash is the higher part of entry and value is its lower part. This determines the features of this opclass. Since path is hashed and it is higher part of entry we need to know the full path to the value in order to use it for search. However, once path is specified we can use both exact and range searches very efficiently.

#### F.24.3.2. `jsonb_value_path_ops`

`jsonb_value_path_ops` represents entry as pair of value and bloom filter of path.

```
(value; bloom(path_item_1) | bloom(path_item_2) | ... | bloom(path_item_n))
```

In comparison of entries value is the higher part of entry and bloom filter of path is its lower part. This determines the features of this opclass. Since value is the higher part of entry we can perform only exact value search efficiently. Range value search is possible as well but we would have to filter all the different paths where matching values occur. Bloom filter over path items allows index usage for conditions containing `%` and `*` in their paths.

#### F.24.3.3. Query optimization

jQuery opclasses perform complex query optimization. Thus it's valuable for developer or administrator to see the result of such optimization. Unfortunately, opclasses aren't allowed to do any custom output to the EXPLAIN. That's why jQuery provides the following functions which allows to see how particular opclass optimizes given query.

- `gin_debug_query_path_value(jsquery)` - for `jsonb_path_value_ops`
- `gin_debug_query_value_path(jsquery)` - for `jsonb_value_path_ops`

Result of these functions is a textual representation of query tree which leaves are GIN search entries. The following examples show different results of query optimization by different opclasses.

```
# SELECT gin_debug_query_path_value('x = 1 AND (*.y = 1 OR y = 2)');
gin_debug_query_path_value
-----
x = 1 , entry 0          +

# SELECT gin_debug_query_value_path('x = 1 AND (*.y = 1 OR y = 2)');
gin_debug_query_value_path
-----
AND                      +
  x = 1 , entry 0        +
  OR                      +
    *.y = 1 , entry 1    +
    y = 2 , entry 2      +
```

Unfortunately, `jsonb` has no statistics yet. That's why `jQuery` optimizer has to do imperative decision while selecting conditions to be evaluated using index. This decision is made by assumption that some condition types are less selective than others. Optimizer divides conditions into the following selectivity class (listed by descending of selectivity).

1. Equality ( $x = c$ )
2. Range ( $c1 < x < c2$ )
3. Inequality ( $x > c$ )
4. Is ( $x$  is type)
5. Any ( $x = *$ )

Optimizer evades index evaluation of less selective conditions when possible. For example, in the  $x = 1$  AND  $y > 0$  query  $x = 1$  is assumed to be more selective than  $y > 0$ . That's why index isn't used for evaluation of  $y > 0$ .

```
# SELECT gin_debug_query_path_value('x = 1 AND y > 0');
gin_debug_query_path_value
-----
x = 1 , entry 0          +
```

With lack of statistics decisions made by optimizer can be inaccurate. That's why `jQuery` supports hints. Comments `/*-- index */` and `/*-- noindex */` placed in the conditions force optimizer to use and not to use index correspondingly.

```
SELECT gin_debug_query_path_value('x = 1 AND y /*-- index */ > 0');
gin_debug_query_path_value
-----
AND                      +
  x = 1 , entry 0        +
  y > 0 , entry 1        +

SELECT gin_debug_query_path_value('x /*-- noindex */ = 1 AND y > 0');
gin_debug_query_path_value
-----
y > 0 , entry 0          +
```

## F.24.5. Credits

Development is sponsored by [Wargaming.net](http://Wargaming.net).

## F.25. lo

The `lo` module provides support for managing Large Objects (also called LOs or BLOBs). This includes a data type `lo` and a trigger `lo_manage`.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.25.1. Rationale

One of the problems with the JDBC driver (and this affects the ODBC driver also), is that the specification assumes that references to BLOBs (Binary Large Objects) are stored within a table, and if that entry is changed, the associated BLOB is deleted from the database.

As Postgres Pro stands, this doesn't occur. Large objects are treated as objects in their own right; a table entry can reference a large object by OID, but there can be multiple table entries referencing the same large object OID, so the system doesn't delete the large object just because you change or remove one such entry.

Now this is fine for Postgres Pro-specific applications, but standard code using JDBC or ODBC won't delete the objects, resulting in orphan objects — objects that are not referenced by anything, and simply occupy disk space.

The `lo` module allows fixing this by attaching a trigger to tables that contain LO reference columns. The trigger essentially just does a `lo_unlink` whenever you delete or modify a value referencing a large object. When you use this trigger, you are assuming that there is only one database reference to any large object that is referenced in a trigger-controlled column!

The module also provides a data type `lo`, which is really just a domain of the `oid` type. This is useful for differentiating database columns that hold large object references from those that are OIDs of other things. You don't have to use the `lo` type to use the trigger, but it may be convenient to use it to keep track of which columns in your database represent large objects that you are managing with the trigger. It is also rumored that the ODBC driver gets confused if you don't use `lo` for BLOB columns.

### F.25.2. How to Use It

Here's a simple example of usage:

```
CREATE TABLE image (title text, raster lo);

CREATE TRIGGER t_raster BEFORE UPDATE OR DELETE ON image
    FOR EACH ROW EXECUTE FUNCTION lo_manage(raster);
```

For each column that will contain unique references to large objects, create a `BEFORE UPDATE OR DELETE` trigger, and give the column name as the sole trigger argument. You can also restrict the trigger to only execute on updates to the column by using `BEFORE UPDATE OF column_name`. If you need multiple `lo` columns in the same table, create a separate trigger for each one, remembering to give a different name to each trigger on the same table.

### F.25.3. Limitations

- Dropping a table will still orphan any objects it contains, as the trigger is not executed. You can avoid this by preceding the `DROP TABLE` with `DELETE FROM table`.

`TRUNCATE` has the same hazard.

If you already have, or suspect you have, orphaned large objects, see the [vacuumlo](#) module to help you clean them up. It's a good idea to run `vacuumlo` occasionally as a back-stop to the `lo_manage` trigger.

- Some frontends may create their own tables, and will not create the associated trigger(s). Also, users may not remember (or know) to create the triggers.

Peter Mount <peter@retep.org.uk>

## F.26. Itree

This module implements a data type `ltree` for representing labels of data stored in a hierarchical tree-like structure. Extensive facilities for searching through label trees are provided.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.26.1. Definitions

A *label* is a sequence of alphanumeric characters and underscores (for example, in C locale the characters `A-Za-z0-9_` are allowed). Labels must be less than 256 characters long.

Examples: `42`, `Personal_Services`

A *label path* is a sequence of zero or more labels separated by dots, for example `L1.L2.L3`, representing a path from the root of a hierarchical tree to a particular node. The length of a label path cannot exceed 65535 labels.

Example: `Top.Countries.Europe.Russia`

The `ltree` module provides several data types:

- `ltree` stores a label path.
- `lquery` represents a regular-expression-like pattern for matching `ltree` values. A simple word matches that label within a path. A star symbol (`*`) matches zero or more labels. These can be joined with dots to form a pattern that must match the whole label path. For example:

```
foo           Match the exact label path foo
*.foo.*       Match any label path containing the label foo
*.foo         Match any label path whose last label is foo
```

Both star symbols and simple words can be quantified to restrict how many labels they can match:

```
*{n}         Match exactly n labels
*{n,}        Match at least n labels
*{n,m}       Match at least n but not more than m labels
*{,m}        Match at most m labels – same as *{0,m}
foo{n,m}     Match at least n but not more than m occurrences of foo
foo{,}       Match any number of occurrences of foo, including zero
```

In the absence of any explicit quantifier, the default for a star symbol is to match any number of labels (that is, `{,}`) while the default for a non-star item is to match exactly once (that is, `{1}`).

There are several modifiers that can be put at the end of a non-star `lquery` item to make it match more than just the exact match:

```
@           Match case-insensitively, for example a@ matches A
*           Match any label with this prefix, for example foo* matches foobar
%           Match initial underscore-separated words
```

The behavior of `%` is a bit complicated. It tries to match words rather than the entire label. For example `foo_bar%` matches `foo_bar_baz` but not `foo_barbaz`. If combined with `*`, prefix matching applies to each word separately, for example `foo_bar%*` matches `foo1_bar2_baz` but not `foo1_br2_baz`.

Also, you can write several possibly-modified non-star items separated with | (OR) to match any of those items, and you can put ! (NOT) at the start of a non-star group to match any label that doesn't match any of the alternatives. A quantifier, if any, goes at the end of the group; it means some number of matches for the group as a whole (that is, some number of labels matching or not matching any of the alternatives).

Here's an annotated example of `lquery`:

```
Top.*{0,2}.sport*@.!football|tennis{1,}.Russ*|Spain
a.  b.      c.      d.      e.
```

This query will match any label path that:

- a. begins with the label `Top`
  - b. and next has zero to two labels before
  - c. a label beginning with the case-insensitive prefix `sport`
  - d. then has one or more labels, none of which match `football` nor `tennis`
  - e. and then ends with a label beginning with `Russ` or exactly matching `Spain`.
- `ltxquery` represents a full-text-search-like pattern for matching `ltree` values. An `ltxquery` value contains words, possibly with the modifiers `@`, `*`, `%` at the end; the modifiers have the same meanings as in `lquery`. Words can be combined with `&` (AND), `|` (OR), `!` (NOT), and parentheses. The key difference from `lquery` is that `ltxquery` matches words without regard to their position in the label path.

Here's an example `ltxquery`:

```
Europe & Russia*@ & !Transportation
```

This will match paths that contain the label `Europe` and any label beginning with `Russia` (case-insensitive), but not paths containing the label `Transportation`. The location of these words within the path is not important. Also, when `%` is used, the word can be matched to any underscore-separated word within a label, regardless of position.

Note: `ltxquery` allows whitespace between symbols, but `ltree` and `lquery` do not.

## F.26.2. Operators and Functions

Type `ltree` has the usual comparison operators `=`, `<>`, `<`, `>`, `<=`, `>=`. Comparison sorts in the order of a tree traversal, with the children of a node sorted by label text. In addition, the specialized operators shown in [Table F.14](#) are available.

**Table F.14. `ltree` Operators**

Operator	Description
<code>ltree @&gt; ltree → boolean</code>	Is left argument an ancestor of right (or equal)?
<code>ltree &lt;@ ltree → boolean</code>	Is left argument a descendant of right (or equal)?
<code>ltree ~ lquery → boolean</code> <code>lquery ~ ltree → boolean</code>	Does <code>ltree</code> match <code>lquery</code> ?
<code>ltree ? lquery[] → boolean</code> <code>lquery[] ? ltree → boolean</code>	Does <code>ltree</code> match any <code>lquery</code> in array?

<b>Operator</b>	<b>Description</b>
<code>ltree @ ltxtquery</code>	<code>→ boolean</code>
<code>ltxtquery @ ltree</code>	<code>→ boolean</code>
	Does <code>ltree</code> match <code>ltxtquery</code> ?
<code>ltree    ltree</code>	<code>→ ltree</code>
	Concatenates <code>ltree</code> paths.
<code>ltree    text</code>	<code>→ ltree</code>
<code>text    ltree</code>	<code>→ ltree</code>
	Converts <code>text</code> to <code>ltree</code> and concatenates.
<code>ltree[] @&gt; ltree</code>	<code>→ boolean</code>
<code>ltree &lt;@ ltree[]</code>	<code>→ boolean</code>
	Does array contain an ancestor of <code>ltree</code> ?
<code>ltree[] &lt;@ ltree</code>	<code>→ boolean</code>
<code>ltree @&gt; ltree[]</code>	<code>→ boolean</code>
	Does array contain a descendant of <code>ltree</code> ?
<code>ltree[] ~ lquery</code>	<code>→ boolean</code>
<code>lquery ~ ltree[]</code>	<code>→ boolean</code>
	Does array contain any path matching <code>lquery</code> ?
<code>ltree[] ? lquery[]</code>	<code>→ boolean</code>
<code>lquery[] ? ltree[]</code>	<code>→ boolean</code>
	Does <code>ltree</code> array contain any path matching any <code>lquery</code> ?
<code>ltree[] @ ltxtquery</code>	<code>→ boolean</code>
<code>ltxtquery @ ltree[]</code>	<code>→ boolean</code>
	Does array contain any path matching <code>ltxtquery</code> ?
<code>ltree[] ?@&gt; ltree</code>	<code>→ ltree</code>
	Returns first array entry that is an ancestor of <code>ltree</code> , or <code>NULL</code> if none.
<code>ltree[] ?&lt;@ ltree</code>	<code>→ ltree</code>
	Returns first array entry that is a descendant of <code>ltree</code> , or <code>NULL</code> if none.
<code>ltree[] ?~ lquery</code>	<code>→ ltree</code>
	Returns first array entry that matches <code>lquery</code> , or <code>NULL</code> if none.
<code>ltree[] ?@ ltxtquery</code>	<code>→ ltree</code>
	Returns first array entry that matches <code>ltxtquery</code> , or <code>NULL</code> if none.

The operators `<@`, `@>`, `@` and `~` have analogues `^<@`, `^@>`, `^@`, `^~`, which are the same except they do not use indexes. These are useful only for testing purposes.

The available functions are shown in [Table F.15](#).

**Table F.15. `ltree` Functions**

<b>Function</b>	<b>Description</b>	<b>Example(s)</b>
<code>subltree ( ltree, start integer, end integer )</code>	<code>→ ltree</code>	
	Returns subpath of <code>ltree</code> from position <code>start</code> to position <code>end-1</code> (counting from 0).	
		<code>subltree('Top.Child1.Child2', 1, 2) → Child1</code>

<b>Function</b>	<b>Description</b>	<b>Example(s)</b>
<code>subpath ( ltree, offset integer, len integer ) → ltree</code>	Returns subpath of <code>ltree</code> starting at position <code>offset</code> , with length <code>len</code> . If <code>offset</code> is negative, subpath starts that far from the end of the path. If <code>len</code> is negative, leaves that many labels off the end of the path.	<code>subpath('Top.Child1.Child2', 0, 2) → Top.Child1</code>
<code>subpath ( ltree, offset integer ) → ltree</code>	Returns subpath of <code>ltree</code> starting at position <code>offset</code> , extending to end of path. If <code>offset</code> is negative, subpath starts that far from the end of the path.	<code>subpath('Top.Child1.Child2', 1) → Child1.Child2</code>
<code>nlevel ( ltree ) → integer</code>	Returns number of labels in path.	<code>nlevel('Top.Child1.Child2') → 3</code>
<code>index ( a ltree, b ltree ) → integer</code>	Returns position of first occurrence of <code>b</code> in <code>a</code> , or -1 if not found.	<code>index('0.1.2.3.5.4.5.6.8.5.6.8', '5.6') → 6</code>
<code>index ( a ltree, b ltree, offset integer ) → integer</code>	Returns position of first occurrence of <code>b</code> in <code>a</code> , or -1 if not found. The search starts at position <code>offset</code> ; negative <code>offset</code> means start <code>-offset</code> labels from the end of the path.	<code>index('0.1.2.3.5.4.5.6.8.5.6.8', '5.6', -4) → 9</code>
<code>text2ltree ( text ) → ltree</code>	Casts <code>text</code> to <code>ltree</code> .	
<code>ltree2text ( ltree ) → text</code>	Casts <code>ltree</code> to <code>text</code> .	
<code>lca ( ltree [, ltree [, ... ]] ) → ltree</code>	Computes longest common ancestor of paths (up to 8 arguments are supported).	<code>lca('1.2.3', '1.2.3.4.5.6') → 1.2</code>
<code>lca ( ltree[] ) → ltree</code>	Computes longest common ancestor of paths in array.	<code>lca(array['1.2.3'::ltree, '1.2.3.4']) → 1.2</code>

### F.26.3. Indexes

`ltree` supports several types of indexes that can speed up the indicated operators:

- B-tree index over `ltree`: `<`, `<=`, `=`, `>=`, `>`
- GiST index over `ltree` (`gist_ltree_ops` opclass): `<`, `<=`, `=`, `>=`, `>`, `@>`, `<@`, `@`, `~`, `?`

`gist_ltree_ops` GiST opclass approximates a set of path labels as a bitmap signature. Its optional integer parameter `siglen` determines the signature length in bytes. The default signature length is 8 bytes. Valid values of signature length are between 1 and 2024 bytes. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

Example of creating such an index with the default signature length of 8 bytes:

```
CREATE INDEX path_gist_idx ON test USING GIST (path);
```

Example of creating such an index with a signature length of 100 bytes:

```
CREATE INDEX path_gist_idx ON test USING GIST (path gist_ltree_ops(siglen=100));
```

- **GiST index over ltree[] (gist\_\_ltree\_ops opclass):** ltree[] <@ ltree, ltree @> ltree[], @, ~, ?

gist\_\_ltree\_ops GiST opclass works similarly to gist\_ltree\_ops and also takes signature length as a parameter. The default value of siglen in gist\_\_ltree\_ops is 28 bytes.

Example of creating such an index with the default signature length of 28 bytes:

```
CREATE INDEX path_gist_idx ON test USING GIST (array_path);
```

Example of creating such an index with a signature length of 100 bytes:

```
CREATE INDEX path_gist_idx ON test USING GIST (array_path
gist__ltree_ops(siglen=100));
```

Note: This index type is lossy.

### F.26.4. Example

This example uses the following data (also available in file contrib/ltree/ltreetest.sql in the source distribution):

```
CREATE TABLE test (path ltree);
INSERT INTO test VALUES ('Top');
INSERT INTO test VALUES ('Top.Science');
INSERT INTO test VALUES ('Top.Science.Astronomy');
INSERT INTO test VALUES ('Top.Science.Astronomy.Astrophysics');
INSERT INTO test VALUES ('Top.Science.Astronomy.Cosmology');
INSERT INTO test VALUES ('Top.Hobbies');
INSERT INTO test VALUES ('Top.Hobbies.Amateurs_Astronomy');
INSERT INTO test VALUES ('Top.Collections');
INSERT INTO test VALUES ('Top.Collections.Pictures');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy.Stars');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy.Galaxies');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy.Astronauts');
CREATE INDEX path_gist_idx ON test USING GIST (path);
CREATE INDEX path_idx ON test USING BTREE (path);
```

Now, we have a table test populated with data describing the hierarchy shown below:

We can do inheritance:

```
ltreetest=> SELECT path FROM test WHERE path <@ 'Top.Science';
           path
```

```
-----
Top.Science
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
```

```
Top.Science.Astronomy.Cosmology
(4 rows)
```

Here are some examples of path matching:

```
ltreetest=> SELECT path FROM test WHERE path ~ '*.Astronomy.*';
           path
```

```
-----
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
Top.Collections.Pictures.Astronomy
Top.Collections.Pictures.Astronomy.Stars
Top.Collections.Pictures.Astronomy.Galaxies
Top.Collections.Pictures.Astronomy.Astronauts
(7 rows)
```

```
ltreetest=> SELECT path FROM test WHERE path ~ '!.!pictures@.Astronomy.*';
           path
```

```
-----
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
(3 rows)
```

Here are some examples of full text search:

```
ltreetest=> SELECT path FROM test WHERE path @ 'Astro*% & !pictures@';
           path
```

```
-----
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
Top.Hobbies.Amateurs_Astronomy
(4 rows)
```

```
ltreetest=> SELECT path FROM test WHERE path @ 'Astro* & !pictures@';
           path
```

```
-----
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
(3 rows)
```

Path construction using functions:

```
ltreetest=> SELECT subpath(path,0,2) || 'Space' || subpath(path,2) FROM test WHERE path <@
           'Top.Science.Astronomy';
           ?column?
```

```
-----
Top.Science.Space.Astronomy
Top.Science.Space.Astronomy.Astrophysics
Top.Science.Space.Astronomy.Cosmology
(3 rows)
```

We could simplify this by creating a SQL function that inserts a label at a specified position in a path:

```
CREATE FUNCTION ins_label(ltree, int, text) RETURNS ltree
AS 'select subpath($1,0,$2) || $3 || subpath($1,$2);'
LANGUAGE SQL IMMUTABLE;
```

```
ltreetest=> SELECT ins_label(path,2,'Space') FROM test WHERE path <@
  'Top.Science.Astronomy';
           ins_label
-----
Top.Science.Space.Astronomy
Top.Science.Space.Astronomy.Astrophysics
Top.Science.Space.Astronomy.Cosmology
(3 rows)
```

## F.26.5. Transforms

Additional extensions are available that implement transforms for the `ltree` type for PL/Python. The extensions are called `ltree_plpythonu`, `ltree_plpython2u`, and `ltree_plpython3u` (see [Section 43.1](#) for the PL/Python naming convention). If you install these transforms and specify them when creating a function, `ltree` values are mapped to Python lists. (The reverse is currently not supported, however.)

### Caution

It is strongly recommended that the transform extensions be installed in the same schema as `ltree`. Otherwise there are installation-time security hazards if a transform extension's schema contains objects defined by a hostile user.

## F.26.6. Authors

All work was done by Teodor Sigaev (<teodor@stack.net>) and Oleg Bartunov (<oleg@sai.msu.su>). See <http://www.sai.msu.su/~megera/postgres/gist/> for additional information. Authors would like to thank Eugeny Rodichev for helpful discussions. Comments and bug reports are welcome.

## F.27. mchar

The `mchar` module provides additional data types for compatibility with Microsoft SQL Server (MS SQL).

### F.27.1. Overview

This module has been designed to improve 1C Enterprise support, most popular Russian CRM and ERP system.

It implements types `MCHAR` and `MVARCHAR`, which are bug-to-bug compatible with MS SQL `CHAR` and `VARCHAR` respectively. Additionally, these types use `libcicu` for comparison and case conversion, so their behavior is identical across different operating systems.

Postgres Pro also includes [citext](#) extension which provides types similar to `MCHAR`. But this extension doesn't emulate MS-SQL behavior concerning end-of-value whitespace.

Differences from Postgres Pro standard `CHAR` and `VARCHAR` are:

- Case insensitive comparison
- Handling of the whitespace at the end of string
- These types are always stored as two-byte unicode value regardless of database encoding.

### F.27.2. Additional types

- `mchar` — analog of the MS SQL char type
- `mvarchar` — analog of the MS SQL varchar type

### F.27.3. MCHAR and MVARCHAR features

- Defines `length(str)` function
- Defines `substr(str, pos[, length])` function
- Defines `||` operator, which would be applied to concatenate any (mchar and mvarchar) arguments
- Defines set of operators: `<`, `<=`, `=`, `>=`, `>` for case-insensitive comparison (LibICU)
- Defines set of operators: `&<`, `&<=`, `&=`, `&>=`, `&>` to case-sensitive comparison (LibICU)
- Implicit cast between `mchar` and `mvarchar` types
- B-tree and Hash-index support
- The `LIKE [ESCAPE]` operator support
- The `SIMILAR TO [ESCAPE]` operator support
- The `~` operator (POSIX regexp) support
- Index support for the `LIKE` operator

### F.27.4. Authors

Teodor Sigaev <teodor@sigaev.ru>

## F.28. online\_analyze

The `online_analyze` module provides a set of features that immediately update statistics after `INSERT`, `UPDATE`, `DELETE`, or `SELECT INTO` operations for the affected tables.

### F.28.1. Module Loading

To use `online_analyze` module, load the shared library:

```
LOAD 'online_analyze';
```

### F.28.2. Module Configuration

You can configure `online_analyze` using the following custom variables (default values are shown):

- `online_analyze.enable = on`  
Enables `online_analyze`.
- `online_analyze.verbose = on`  
Executes `ANALYZE VERBOSE`.

#### Note

Since `verbose` is a reserved SQL key word, this parameter has to be double-quoted when used in SQL queries. For example:

```
ALTER SYSTEM SET "online_analyze.verbose" = 'off';
```

- `online_analyze.scale_factor = 0.1`  
Fraction of table size to start online analysis (similar to [autovacuum\\_analyze\\_scale\\_factor](#)).

- `online_analyze.threshold = 50`

Minimum number of row updates before starting online analysis (similar to [autovacuum\\_analyze\\_threshold](#)).

- `online_analyze.min_interval = 10000`

Minimum time interval between `ANALYZE` calls per table, in milliseconds.

- `online_analyze.table_type = "all"`

Type(s) of tables for online analysis. Possible values are: `all`, `persistent`, `temporary`, `none`.

- `online_analyze.exclude_tables = ""`

List of tables to exclude from online analysis.

- `online_analyze.include_tables = ""`

List of tables to include in online analysis (`online_analyze.include_tables` overrides `online_analyze.exclude_tables`).

- `online_analyze.local_tracking = off`

Enables per-backend tracking for temporary tables by `online_analyze`. When this variable is set to `off`, `online_analyze` uses the default system statistics for temporary tables.

- `online_analyze.lower_limit = 0`

Minimum number of rows in a table required to trigger `online_analyze`.

- `online_analyze.capacity_threshold = 100000`

Maximum number of temporary tables to store in local cache.

### F.28.3. Authors

Teodor Sigaev <teodor@sigaev.ru>

## F.29. pageinspect

The `pageinspect` module provides functions that allow you to inspect the contents of database pages at a low level, which is useful for debugging purposes. All of these functions may be used only by superusers.

### F.29.1. General Functions

`get_raw_page(relname text, fork text, blkno int)` returns `bytea`

`get_raw_page` reads the specified block of the named relation and returns a copy as a `bytea` value. This allows a single time-consistent copy of the block to be obtained. `fork` should be `'main'` for the main data fork, `'fsm'` for the free space map, `'vm'` for the visibility map, or `'init'` for the initialization fork.

`get_raw_page(relname text, blkno int)` returns `bytea`

A shorthand version of `get_raw_page`, for reading from the main fork. Equivalent to `get_raw_page(relname, 'main', blkno)`

`page_header(page bytea)` returns `record`

`page_header` shows fields that are common to all Postgres Pro heap and index pages.

A page image obtained with `get_raw_page` should be passed as argument. For example:

```
test=# SELECT * FROM page_header(get_raw_page('pg_class', 0));
   lsn   | checksum | flags | lower | upper | special | pagesize | version |
-----+-----+-----+-----+-----+-----+-----+-----+
0/24A1B50 |          0 |      1 | 232 | 368 |      8192 | 8192 | 4 |
0
```

The returned columns correspond to the fields in the `PageHeaderData` struct.

The `checksum` field is the checksum stored in the page, which might be incorrect if the page is somehow corrupted. If data checksums are not enabled for this instance, then the value stored is meaningless.

`page_checksum(page bytea, blkno int4)` returns `smallint`

`page_checksum` computes the checksum for the page, as if it was located at the given block.

A page image obtained with `get_raw_page` should be passed as argument. For example:

```
test=# SELECT page_checksum(get_raw_page('pg_class', 0), 0);
 page_checksum
-----
          13443
```

Note that the checksum depends on the block number, so matching block numbers should be passed (except when doing esoteric debugging).

The checksum computed with this function can be compared with the `checksum` result field of the function `page_header`. If data checksums are enabled for this instance, then the two values should be equal.

`fsm_page_contents(page bytea)` returns `text`

`fsm_page_contents` shows the internal node structure of a FSM page. For example:

```
test=# SELECT fsm_page_contents(get_raw_page('pg_class', 'fsm', 0));
```

The output is a multiline string, with one line per node in the binary tree within the page. Only those nodes that are not zero are printed. The so-called "next" pointer, which points to the next slot to be returned from the page, is also printed.

## F.29.2. Heap Functions

`heap_page_items(page bytea)` returns `setof record`

`heap_page_items` shows all line pointers on a heap page. For those line pointers that are in use, tuple headers as well as tuple raw data are also shown. All tuples are shown, whether or not the tuples were visible to an MVCC snapshot at the time the raw page was copied.

A heap page image obtained with `get_raw_page` should be passed as argument. For example:

```
test=# SELECT * FROM heap_page_items(get_raw_page('pg_class', 0));
```

The `heap_tuple_infomask_flags` function can be used to unpack the flag bits of `t_infomask` and `t_infomask2` for heap tuples.

`tuple_data_split(rel_oid oid, t_data bytea, t_infomask integer, t_infomask2 integer, t_bits text [, do_detoast bool])` returns `bytea[]`

`tuple_data_split` splits tuple data into attributes in the same way as backend internals.

```
test=# SELECT tuple_data_split('pg_class'::regclass, t_data, t_infomask,
    t_infomask2, t_bits) FROM heap_page_items(get_raw_page('pg_class', 0));
```

This function should be called with the same arguments as the return attributes of `heap_page_items`.

If `do_detoast` is true, attributes will be detoasted as needed. Default value is false.

`heap_page_item_attrs(page bytea, rel_oid regclass [, do_detoast bool])` returns set of record

`heap_page_item_attrs` is equivalent to `heap_page_items` except that it returns tuple raw data as an array of attributes that can optionally be detoasted by `do_detoast` which is false by default.

A heap page image obtained with `get_raw_page` should be passed as argument. For example:

```
test=# SELECT * FROM heap_page_item_attrs(get_raw_page('pg_class', 0),
    'pg_class'::regclass);
```

`heap_tuple_infomask_flags(t_infomask integer, t_infomask2 integer)` returns record

`heap_tuple_infomask_flags` decodes the `t_infomask` and `t_infomask2` returned by `heap_page_items` into a human-readable set of arrays made of flag names, with one column for all the flags and one column for combined flags. For example:

```
test=# SELECT t_ctid, raw_flags, combined_flags
    FROM heap_page_items(get_raw_page('pg_class', 0)),
    LATERAL heap_tuple_infomask_flags(t_infomask, t_infomask2)
    WHERE t_infomask IS NOT NULL OR t_infomask2 IS NOT NULL;
```

This function should be called with the same arguments as the return attributes of `heap_page_items`.

Combined flags are displayed for source-level macros that take into account the value of more than one raw bit, such as `HEAP_XMIN_FROZEN`.

## F.29.3. B-Tree Functions

`bt_metap(relname text)` returns record

`bt_metap` returns information about a B-tree index's metapage. For example:

```
test=# SELECT * FROM bt_metap('pg_cast_oid_index');
-[ RECORD 1 ]-----+-----
magic          | 340322
version        | 4
root           | 1
level          | 0
fastroot       | 1
fastlevel      | 0
oldest_xact    | 582
last_cleanup_num_tuples | 1000
allequalimage  | f
```

`bt_page_stats(relname text, blkno int)` returns record

`bt_page_stats` returns summary information about single pages of B-tree indexes. For example:

```
test=# SELECT * FROM bt_page_stats('pg_cast_oid_index', 1);
-[ RECORD 1 ]-+-----
blkno         | 1
type          | 1
live_items    | 224
dead_items    | 0
avg_item_size | 16
page_size     | 8192
free_size     | 3668
```

```

btpo_prev      | 0
btpo_next      | 0
btpo           | 0
btpo_flags     | 3

```

bt\_page\_items(relname text, blkno int) returns setof record

bt\_page\_items returns detailed information about all of the items on a B-tree index page. For example:

```

test=# SELECT itemoffset, ctid, itemlen, nulls, vars, data, dead, htid, tids[0:2] AS
some_tids

```

```

      FROM bt_page_items('tenk2_hundred', 5);
 itemoffset |   ctid   | itemlen | nulls | vars |          data          | dead |
 htid      | some_tids
-----+-----+-----+-----+-----+-----+-----+-----+-----+
 1 | (16,1)   |    16 | f     | f   | 30 00 00 00 00 00 00 00 |      |
 |
 2 | (16,8292)|   616 | f     | f   | 24 00 00 00 00 00 00 00 | f     |
(1,6) | {"(1,6)","(10,22)"}
 3 | (16,8292)|   616 | f     | f   | 25 00 00 00 00 00 00 00 | f     |
(1,18) | {"(1,18)","(4,22)"}
 4 | (16,8292)|   616 | f     | f   | 26 00 00 00 00 00 00 00 | f     |
(4,18) | {"(4,18)","(6,17)"}
 5 | (16,8292)|   616 | f     | f   | 27 00 00 00 00 00 00 00 | f     |
(1,2)  | {"(1,2)","(1,19)"}
 6 | (16,8292)|   616 | f     | f   | 28 00 00 00 00 00 00 00 | f     |
(2,24) | {"(2,24)","(4,11)"}
 7 | (16,8292)|   616 | f     | f   | 29 00 00 00 00 00 00 00 | f     |
(2,17) | {"(2,17)","(11,2)"}
 8 | (16,8292)|   616 | f     | f   | 2a 00 00 00 00 00 00 00 | f     |
(0,25) | {"(0,25)","(3,20)"}
 9 | (16,8292)|   616 | f     | f   | 2b 00 00 00 00 00 00 00 | f     |
(0,10) | {"(0,10)","(0,14)"}
10 | (16,8292)|   616 | f     | f   | 2c 00 00 00 00 00 00 00 | f     |
(1,3)  | {"(1,3)","(3,9)"}
11 | (16,8292)|   616 | f     | f   | 2d 00 00 00 00 00 00 00 | f     |
(6,28) | {"(6,28)","(11,1)"}
12 | (16,8292)|   616 | f     | f   | 2e 00 00 00 00 00 00 00 | f     |
(0,27) | {"(0,27)","(1,13)"}
13 | (16,8292)|   616 | f     | f   | 2f 00 00 00 00 00 00 00 | f     |
(4,17) | {"(4,17)","(4,21)"}
(13 rows)

```

This is a B-tree leaf page. All tuples that point to the table happen to be posting list tuples (all of which store a total of 100 6 byte TIDs). There is also a “high key” tuple at itemoffset number 1. ctid is used to store encoded information about each tuple in this example, though leaf page tuples often store a heap TID directly in the ctid field instead. tids is the list of TIDs stored as a posting list.

In an internal page (not shown), the block number part of ctid is a “downlink”, which is a block number of another page in the index itself. The offset part (the second number) of ctid stores encoded information about the tuple, such as the number of columns present (suffix truncation may have removed unneeded suffix columns). Truncated columns are treated as having the value “minus infinity”.

htid shows a heap TID for the tuple, regardless of the underlying tuple representation. This value may match ctid, or may be decoded from the alternative representations used by posting list tuples and tuples from internal pages. Tuples in internal pages usually have the implementation level heap TID column truncated away, which is represented as a NULL htid value.

Note that the first item on any non-rightmost page (any page with a non-zero value in the `btpo_next` field) is the page's "high key", meaning its `data` serves as an upper bound on all items appearing on the page, while its `ctid` field does not point to another block. Also, on internal pages, the first real data item (the first item that is not a high key) reliably has every column truncated away, leaving no actual value in its `data` field. Such an item does have a valid downlink in its `ctid` field, however.

For more details about the structure of B-tree indexes, see [Section 59.4.1](#). For more details about deduplication and posting lists, see [Section 59.4.2](#).

`bt_page_items(page bytea)` returns setof record

It is also possible to pass a page to `bt_page_items` as a `bytea` value. A page image obtained with `get_raw_page` should be passed as argument. So the last example could also be rewritten like this:

```
test=# SELECT itemoffset, ctid, itemlen, nulls, vars, data, dead, htid, tids[0:2] AS
some_tids
      FROM bt_page_items(get_raw_page('tenk2_hundred', 5));
 itemoffset |   ctid   | itemlen | nulls | vars |          data          | dead |
 htid  |   some_tids
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+-----+-----+
          1 | (16,1)   |      16 | f     | f   | 30 00 00 00 00 00 00 00 |      |
          |
          2 | (16,8292)|     616 | f     | f   | 24 00 00 00 00 00 00 00 | f     |
(1,6)   | {"(1,6)","(10,22)"}
          3 | (16,8292)|     616 | f     | f   | 25 00 00 00 00 00 00 00 | f     |
(1,18)  | {"(1,18)","(4,22)"}
          4 | (16,8292)|     616 | f     | f   | 26 00 00 00 00 00 00 00 | f     |
(4,18)  | {"(4,18)","(6,17)"}
          5 | (16,8292)|     616 | f     | f   | 27 00 00 00 00 00 00 00 | f     |
(1,2)   | {"(1,2)","(1,19)"}
          6 | (16,8292)|     616 | f     | f   | 28 00 00 00 00 00 00 00 | f     |
(2,24)  | {"(2,24)","(4,11)"}
          7 | (16,8292)|     616 | f     | f   | 29 00 00 00 00 00 00 00 | f     |
(2,17)  | {"(2,17)","(11,2)"}
          8 | (16,8292)|     616 | f     | f   | 2a 00 00 00 00 00 00 00 | f     |
(0,25)  | {"(0,25)","(3,20)"}
          9 | (16,8292)|     616 | f     | f   | 2b 00 00 00 00 00 00 00 | f     |
(0,10)  | {"(0,10)","(0,14)"}
         10 | (16,8292)|     616 | f     | f   | 2c 00 00 00 00 00 00 00 | f     |
(1,3)   | {"(1,3)","(3,9)"}
         11 | (16,8292)|     616 | f     | f   | 2d 00 00 00 00 00 00 00 | f     |
(6,28)  | {"(6,28)","(11,1)"}
         12 | (16,8292)|     616 | f     | f   | 2e 00 00 00 00 00 00 00 | f     |
(0,27)  | {"(0,27)","(1,13)"}
         13 | (16,8292)|     616 | f     | f   | 2f 00 00 00 00 00 00 00 | f     |
(4,17)  | {"(4,17)","(4,21)"}
(13 rows)
```

All the other details are the same as explained in the previous item.

## F.29.4. BRIN Functions

`brin_page_type(page bytea)` returns text

`brin_page_type` returns the page type of the given BRIN index page, or throws an error if the page is not a valid BRIN page. For example:

```
test=# SELECT brin_page_type(get_raw_page('brinidx', 0));
 brin_page_type
-----
```

meta

brin\_metapage\_info(page bytea) returns record

brin\_metapage\_info returns assorted information about a BRIN index metapage. For example:

```
test=# SELECT * FROM brin_metapage_info(get_raw_page('brinidx', 0));
  magic      | version | pagesperpage | lastrevmappage
-----+-----+-----+-----
0xA8109CFA |      1 |           4 |           2
```

brin\_revmap\_data(page bytea) returns setof tid

brin\_revmap\_data returns the list of tuple identifiers in a BRIN index range map page. For example:

```
test=# SELECT * FROM brin_revmap_data(get_raw_page('brinidx', 2)) LIMIT 5;
 pages
-----
(6,137)
(6,138)
(6,139)
(6,140)
(6,141)
```

brin\_page\_items(page bytea, index oid) returns setof record

brin\_page\_items returns the data stored in the BRIN data page. For example:

```
test=# SELECT * FROM brin_page_items(get_raw_page('brinidx', 5),
                                     'brinidx')
      ORDER BY blknum, attnum LIMIT 6;
 itemoffset | blknum | attnum | allnulls | hasnulls | placeholder | value
-----+-----+-----+-----+-----+-----+-----
      137 |      0 |      1 | t         | f         | f           |
      137 |      0 |      2 | f         | f         | f           | {1 .. 88}
      138 |      4 |      1 | t         | f         | f           |
      138 |      4 |      2 | f         | f         | f           | {89 .. 176}
      139 |      8 |      1 | t         | f         | f           |
      139 |      8 |      2 | f         | f         | f           | {177 .. 264}
```

The returned columns correspond to the fields in the `BrinMemTuple` and `BrinValues` structs.

## F.29.5. GIN Functions

gin\_metapage\_info(page bytea) returns record

gin\_metapage\_info returns information about a GIN index metapage. For example:

```
test=# SELECT * FROM gin_metapage_info(get_raw_page('gin_index', 0));
-[ RECORD 1 ]-----
pending_head      | 4294967295
pending_tail      | 4294967295
tail_free_size    | 0
n_pending_pages   | 0
n_pending_tuples  | 0
n_total_pages     | 7
n_entry_pages     | 6
n_data_pages      | 0
n_entries         | 693
version           | 2
```

gin\_page\_opaque\_info(page bytea) returns record

gin\_page\_opaque\_info returns information about a GIN index opaque area, like the page type. For example:

```
test=# SELECT * FROM gin_page_opaque_info(get_raw_page('gin_index', 2));
 rightlink | maxoff | flags
-----+-----+-----
          5 |        0 | {data,leaf,compressed}
(1 row)
```

gin\_leafpage\_items(page bytea) returns setof record

gin\_leafpage\_items returns information about the data stored in a GIN leaf page. For example:

```
test=# SELECT first_tid, nbytes, tids[0:5] AS some_tids
       FROM gin_leafpage_items(get_raw_page('gin_test_idx', 2));
 first_tid | nbytes | some_tids
-----+-----+-----
(8,41)    |    244 | {"(8,41)","(8,43)","(8,44)","(8,45)","(8,46)"}
(10,45)   |    248 | {"(10,45)","(10,46)","(10,47)","(10,48)","(10,49)"}
(12,52)   |    248 | {"(12,52)","(12,53)","(12,54)","(12,55)","(12,56)"}
(14,59)   |    320 | {"(14,59)","(14,60)","(14,61)","(14,62)","(14,63)"}
(167,16)  |    376 | {"(167,16)","(167,17)","(167,18)","(167,19)","(167,20)"}
(170,30)  |    376 | {"(170,30)","(170,31)","(170,32)","(170,33)","(170,34)"}
(173,44)  |    197 | {"(173,44)","(173,45)","(173,46)","(173,47)","(173,48)"}
(7 rows)
```

## F.29.6. Hash Functions

hash\_page\_type(page bytea) returns text

hash\_page\_type returns page type of the given HASH index page. For example:

```
test=# SELECT hash_page_type(get_raw_page('con_hash_index', 0));
 hash_page_type
-----
metapage
```

hash\_page\_stats(page bytea) returns setof record

hash\_page\_stats returns information about a bucket or overflow page of a HASH index. For example:

```
test=# SELECT * FROM hash_page_stats(get_raw_page('con_hash_index', 1));
-[ RECORD 1 ]-----+-----
live_items      | 407
dead_items      | 0
page_size       | 8192
free_size       | 8
hasho_prevblkno | 4096
hasho_nextblkno | 8474
hasho_bucket    | 0
hasho_flag      | 66
hasho_page_id   | 65408
```

hash\_page\_items(page bytea) returns setof record

hash\_page\_items returns information about the data stored in a bucket or overflow page of a HASH index page. For example:

```
test=# SELECT * FROM hash_page_items(get_raw_page('con_hash_index', 1)) LIMIT 5;
 itemoffset | ctid | data
-----+-----+-----
          1 | (899,77) | 1053474816
          2 | (897,29) | 1053474816
          3 | (894,207) | 1053474816
          4 | (892,159) | 1053474816
          5 | (890,111) | 1053474816
```

hash\_bitmap\_info(index oid, blkno int) returns record

hash\_bitmap\_info shows the status of a bit in the bitmap page for a particular overflow page of HASH index. For example:

```
test=# SELECT * FROM hash_bitmap_info('con_hash_index', 2052);
 bitmapblkno | bitmapbit | bitstatus
-----+-----+-----
           65 |          3 | t
```

hash\_metapage\_info(page bytea) returns record

hash\_metapage\_info returns information stored in the meta page of a HASH index. For example:

```
test=# SELECT magic, version, ntuples, ffactor, bsize, bmsize, bmshift,
test-#       maxbucket, highmask, lowmask, ovflpoint, firstfree, nmaps, procid,
test-#       regexp_replace(spares::text, '(,0)*}', '{}') as spares,
test-#       regexp_replace(mapp::text, '(,0)*}', '{}') as mapp
test-# FROM hash_metapage_info(get_raw_page('con_hash_index', 0));
-[ RECORD 1 ]-----
-----
magic       | 105121344
version     | 4
ntuples     | 500500
ffactor     | 40
bsize       | 8152
bmsize      | 4096
bmshift     | 15
maxbucket   | 12512
highmask    | 16383
lowmask     | 8191
ovflpoint   | 28
firstfree   | 1204
nmaps       | 1
procid      | 450
spares      | {0,0,0,0,0,0,1,1,1,1,1,1,1,1,3,4,4,4,45,55,58,59,
508,567,628,704,1193,1202,1204}
mapp        | {65}
```

## F.30. passwordcheck

The passwordcheck module checks users' passwords whenever they are set with [CREATE ROLE](#) or [ALTER ROLE](#). If a password is considered too weak, it will be rejected and the command will terminate with an error.

To enable this module, add '\$libdir/passwordcheck' to [shared\\_preload\\_libraries](#) in postgresql.conf, then restart the server.

### Caution

To prevent unencrypted passwords from being sent across the network, written to the server log or otherwise stolen by a database administrator, Postgres Pro allows the user to supply pre-encrypted passwords. Many client programs make use of this functionality and encrypt the password before sending it to the server.

This limits the usefulness of the passwordcheck module, because in that case it can only try to guess the password. For this reason, passwordcheck is not recommended if your security requirements are high. It is more secure to use an external authentication method such as GSSAPI (see [Chapter 19](#)) than to rely on passwords within the database.

## F.31. pg\_buffercache

The `pg_buffercache` module provides a means for examining what's happening in the shared buffer cache in real time.

The module provides a C function `pg_buffercache_pages` that returns a set of records, plus a view `pg_buffercache` that wraps the function for convenient use.

By default, use is restricted to superusers and members of the `pg_monitor` role. Access may be granted to others using `GRANT`.

### F.31.1. The pg\_buffercache View

The definitions of the columns exposed by the view are shown in [Table F.16](#).

**Table F.16. pg\_buffercache Columns**

Column Type	Description
<code>bufferid integer</code>	ID, in the range 1.. <code>shared_buffers</code>
<code>relfilenode oid (references pg_class .relfilenode)</code>	Filenode number of the relation
<code>reltablespace oid (references pg_tablespace .oid)</code>	Tablespace OID of the relation
<code>reldatabase oid (references pg_database .oid)</code>	Database OID of the relation
<code>relforknumber smallint</code>	Fork number within the relation; see <code>include/common/relpath.h</code>
<code>relblocknumber bigint</code>	Page number within the relation
<code>isdirty boolean</code>	Is the page dirty?
<code>usagecount smallint</code>	Clock-sweep access count
<code>pinning_backends integer</code>	Number of backends pinning this buffer

There is one row for each buffer in the shared cache. Unused buffers are shown with all fields null except `bufferid`. Shared system catalogs are shown as belonging to database zero.

Because the cache is shared by all the databases, there will normally be pages from relations not belonging to the current database. This means that there may not be matching join rows in `pg_class` for some rows, or that there could even be incorrect joins. If you are trying to join against `pg_class`, it's a good idea to restrict the join to rows having `reldatabase` equal to the current database's OID or zero.

Since buffer manager locks are not taken to copy the buffer state data that the view will display, accessing `pg_buffercache` view has less impact on normal buffer activity but it doesn't provide a consistent set of results across all buffers. However, we ensure that the information of each buffer is self-consistent.

### F.31.2. Sample Output

```
regression=# SELECT n.nspname, c.relname, count(*) AS buffers
              FROM pg_buffercache b JOIN pg_class c
              ON b.relfilenode = pg_relation_filenode(c.oid) AND
```

```

        b.reldatabase IN (0, (SELECT oid FROM pg_database
                               WHERE datname = current_database()))
JOIN pg_namespace n ON n.oid = c.relnamespace
GROUP BY n.nspname, c.relname
ORDER BY 3 DESC
LIMIT 10;

```

nspname	relname	buffers
public	delete_test_table	593
public	delete_test_table_pkey	494
pg_catalog	pg_attribute	472
public	quad_poly_tbl	353
public	tenk2	349
public	tenk1	349
public	gin_test_idx	306
pg_catalog	pg_largeobject	206
public	gin_test_tbl	188
public	spgist_text_tbl	182

(10 rows)

### F.31.3. Authors

Mark Kirkwood <markir@paradise.net.nz>

Design suggestions: Neil Conway <neilc@samurai.com>

Debugging advice: Tom Lane <tgl@sss.pgh.pa.us>

## F.32. pgcrypto

The `pgcrypto` module provides cryptographic functions for Postgres Pro.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.32.1. General Hashing Functions

#### F.32.1.1. `digest()`

`digest(data text, type text)` returns `bytea`  
`digest(data bytea, type text)` returns `bytea`

Computes a binary hash of the given *data*. *type* is the algorithm to use. Standard algorithms are `md5`, `sha1`, `sha224`, `sha256`, `sha384` and `sha512`. If `pgcrypto` was built with OpenSSL, more algorithms are available, as detailed in [Table F.20](#).

If you want the `digest` as a hexadecimal string, use `encode()` on the result. For example:

```

CREATE OR REPLACE FUNCTION sha1(bytea) returns text AS $$
    SELECT encode(digest($1, 'sha1'), 'hex')
$$ LANGUAGE SQL STRICT IMMUTABLE;

```

#### F.32.1.2. `hmac()`

`hmac(data text, key text, type text)` returns `bytea`  
`hmac(data bytea, key bytea, type text)` returns `bytea`

Calculates hashed MAC for *data* with key *key*. *type* is the same as in `digest()`.

This is similar to `digest()` but the hash can only be recalculated knowing the key. This prevents the scenario of someone altering data and also changing the hash to match.

If the key is larger than the hash block size it will first be hashed and the result will be used as key.

## F.32.2. Password Hashing Functions

The functions `crypt()` and `gen_salt()` are specifically designed for hashing passwords. `crypt()` does the hashing and `gen_salt()` prepares algorithm parameters for it.

The algorithms in `crypt()` differ from the usual MD5 or SHA1 hashing algorithms in the following respects:

1. They are slow. As the amount of data is so small, this is the only way to make brute-forcing passwords hard.
2. They use a random value, called the *salt*, so that users having the same password will have different encrypted passwords. This is also an additional defense against reversing the algorithm.
3. They include the algorithm type in the result, so passwords hashed with different algorithms can co-exist.
4. Some of them are adaptive — that means when computers get faster, you can tune the algorithm to be slower, without introducing incompatibility with existing passwords.

Table F.17 lists the algorithms supported by the `crypt()` function.

**Table F.17. Supported Algorithms for `crypt()`**

Algorithm	Max Password Length	Adaptive?	Salt Bits	Output Length	Description
bf	72	yes	128	60	Blowfish-based, variant 2a
md5	unlimited	no	48	34	MD5-based crypt
xdes	8	yes	24	20	Extended DES
des	8	no	12	13	Original UNIX crypt

### F.32.2.1. `crypt()`

`crypt(password text, salt text)` returns text

Calculates a `crypt(3)`-style hash of *password*. When storing a new password, you need to use `gen_salt()` to generate a new *salt* value. To check a password, pass the stored hash value as *salt*, and test whether the result matches the stored value.

Example of setting a new password:

```
UPDATE ... SET pswhash = crypt('new password', gen_salt('md5'));
```

Example of authentication:

```
SELECT (pswhash = crypt('entered password', pswhash)) AS pswmatch FROM ... ;
```

This returns `true` if the entered password is correct.

### F.32.2.2. `gen_salt()`

`gen_salt(type text [, iter_count integer ])` returns text

Generates a new random salt string for use in `crypt()`. The salt string also tells `crypt()` which algorithm to use.

The *type* parameter specifies the hashing algorithm. The accepted types are: `des`, `xdes`, `md5` and `bf`.

The *iter\_count* parameter lets the user specify the iteration count, for algorithms that have one. The higher the count, the more time it takes to hash the password and therefore the more time to break it.

Although with too high a count the time to calculate a hash may be several years — which is somewhat impractical. If the `iter_count` parameter is omitted, the default iteration count is used. Allowed values for `iter_count` depend on the algorithm and are shown in [Table F.18](#).

**Table F.18. Iteration Counts for `crypt()`**

Algorithm	Default	Min	Max
xdes	725	1	16777215
bf	6	4	31

For `xdes` there is an additional limitation that the iteration count must be an odd number.

To pick an appropriate iteration count, consider that the original DES `crypt` was designed to have the speed of 4 hashes per second on the hardware of that time. Slower than 4 hashes per second would probably dampen usability. Faster than 100 hashes per second is probably too fast.

[Table F.19](#) gives an overview of the relative slowness of different hashing algorithms. The table shows how much time it would take to try all combinations of characters in an 8-character password, assuming that the password contains either only lower case letters, or upper- and lower-case letters and numbers. In the `crypt-bf` entries, the number after a slash is the `iter_count` parameter of `gen_salt`.

**Table F.19. Hash Algorithm Speeds**

Algorithm	Hashes/sec	For [a-z]	For [A-Za-z0-9]	Duration relative to md5 hash
crypt-bf/8	1792	4 years	3927 years	100k
crypt-bf/7	3648	2 years	1929 years	50k
crypt-bf/6	7168	1 year	982 years	25k
crypt-bf/5	13504	188 days	521 years	12.5k
crypt-md5	171584	15 days	41 years	1k
crypt-des	23221568	157.5 minutes	108 days	7
sha1	37774272	90 minutes	68 days	4
md5 (hash)	150085504	22.5 minutes	17 days	1

Notes:

- The machine used is an Intel Mobile Core i3.
- `crypt-des` and `crypt-md5` algorithm numbers are taken from John the Ripper v1.6.38 `-test` output.
- `md5 hash` numbers are from `mdcrack 1.2`.
- `sha1` numbers are from `lcrack-20031130-beta`.
- `crypt-bf` numbers are taken using a simple program that loops over 1000 8-character passwords. That way I can show the speed with different numbers of iterations. For reference: `john -test` shows 13506 loops/sec for `crypt-bf/5`. (The very small difference in results is in accordance with the fact that the `crypt-bf` implementation in `pgcrypto` is the same one used in John the Ripper.)

Note that “try all combinations” is not a realistic exercise. Usually password cracking is done with the help of dictionaries, which contain both regular words and various mutations of them. So, even somewhat word-like passwords could be cracked much faster than the above numbers suggest, while a 6-character non-word-like password may escape cracking. Or not.

### F.32.3. PGP Encryption Functions

The functions here implement the encryption part of the OpenPGP (RFC 4880) standard. Supported are both symmetric-key and public-key encryption.

An encrypted PGP message consists of 2 parts, or *packets*:

- Packet containing a session key — either symmetric-key or public-key encrypted.
- Packet containing data encrypted with the session key.

When encrypting with a symmetric key (i.e., a password):

1. The given password is hashed using a String2Key (S2K) algorithm. This is rather similar to `crypt()` algorithms — purposefully slow and with random salt — but it produces a full-length binary key.
2. If a separate session key is requested, a new random key will be generated. Otherwise the S2K key will be used directly as the session key.
3. If the S2K key is to be used directly, then only S2K settings will be put into the session key packet. Otherwise the session key will be encrypted with the S2K key and put into the session key packet.

When encrypting with a public key:

1. A new random session key is generated.
2. It is encrypted using the public key and put into the session key packet.

In either case the data to be encrypted is processed as follows:

1. Optional data-manipulation: compression, conversion to UTF-8, and/or conversion of line-endings.
2. The data is prefixed with a block of random bytes. This is equivalent to using a random IV.
3. An SHA1 hash of the random prefix and data is appended.
4. All this is encrypted with the session key and placed in the data packet.

#### F.32.3.1. `pgp_sym_encrypt()`

`pgp_sym_encrypt(data text, psw text [, options text ])` returns `bytea`  
`pgp_sym_encrypt_bytea(data bytea, psw text [, options text ])` returns `bytea`

Encrypt *data* with a symmetric PGP key *psw*. The *options* parameter can contain option settings, as described below.

#### F.32.3.2. `pgp_sym_decrypt()`

`pgp_sym_decrypt(msg bytea, psw text [, options text ])` returns `text`  
`pgp_sym_decrypt_bytea(msg bytea, psw text [, options text ])` returns `bytea`

Decrypt a symmetric-key-encrypted PGP message.

Decrypting `bytea` data with `pgp_sym_decrypt` is disallowed. This is to avoid outputting invalid character data. Decrypting originally textual data with `pgp_sym_decrypt_bytea` is fine.

The *options* parameter can contain option settings, as described below.

#### F.32.3.3. `pgp_pub_encrypt()`

`pgp_pub_encrypt(data text, key bytea [, options text ])` returns `bytea`  
`pgp_pub_encrypt_bytea(data bytea, key bytea [, options text ])` returns `bytea`

Encrypt *data* with a public PGP key *key*. Giving this function a secret key will produce an error.

The *options* parameter can contain option settings, as described below.

#### F.32.3.4. `pgp_pub_decrypt()`

`pgp_pub_decrypt(msg bytea, key bytea [, psw text [, options text ]])` returns `text`  
`pgp_pub_decrypt_bytea(msg bytea, key bytea [, psw text [, options text ]])` returns `bytea`

Decrypt a public-key-encrypted message. *key* must be the secret key corresponding to the public key that was used to encrypt. If the secret key is password-protected, you must give the password in *psw*. If there is no password, but you want to specify options, you need to give an empty password.

Decrypting *bytea* data with `pgp_pub_decrypt` is disallowed. This is to avoid outputting invalid character data. Decrypting originally textual data with `pgp_pub_decrypt_bytea` is fine.

The *options* parameter can contain option settings, as described below.

### F.32.3.5. `pgp_key_id()`

`pgp_key_id(bytea)` returns *text*

`pgp_key_id` extracts the key ID of a PGP public or secret key. Or it gives the key ID that was used for encrypting the data, if given an encrypted message.

It can return 2 special key IDs:

- `SYMKEY`

The message is encrypted with a symmetric key.

- `ANYKEY`

The message is public-key encrypted, but the key ID has been removed. That means you will need to try all your secret keys on it to see which one decrypts it. `pgcrypto` itself does not produce such messages.

Note that different keys may have the same ID. This is rare but a normal event. The client application should then try to decrypt with each one, to see which fits — like handling `ANYKEY`.

### F.32.3.6. `armor()`, `dearmor()`

`armor(data bytea [ , keys text[], values text[] ])` returns *text*

`dearmor(data text)` returns *bytea*

These functions wrap/unwrap binary data into PGP ASCII-armor format, which is basically Base64 with CRC and additional formatting.

If the *keys* and *values* arrays are specified, an *armor header* is added to the armored format for each key/value pair. Both arrays must be single-dimensional, and they must be of the same length. The keys and values cannot contain any non-ASCII characters.

### F.32.3.7. `pgp_armor_headers`

`pgp_armor_headers(data text, key out text, value out text)` returns *setof record*

`pgp_armor_headers()` extracts the armor headers from *data*. The return value is a set of rows with two columns, key and value. If the keys or values contain any non-ASCII characters, they are treated as UTF-8.

### F.32.3.8. Options for PGP Functions

Options are named to be similar to GnuPG. An option's value should be given after an equal sign; separate options from each other with commas. For example:

```
pgp_sym_encrypt(data, psw, 'compress-algo=1, cipher-algo=aes256')
```

All of the options except `convert-crlf` apply only to encrypt functions. Decrypt functions get the parameters from the PGP data.

The most interesting options are probably `compress-algo` and `unicode-mode`. The rest should have reasonable defaults.

#### **F.32.3.8.1. cipher-algo**

Which cipher algorithm to use.

Values: bf, aes128, aes192, aes256 (OpenSSL-only: 3des, cast5)

Default: aes128

Applies to: pgp\_sym\_encrypt, pgp\_pub\_encrypt

#### **F.32.3.8.2. compress-algo**

Which compression algorithm to use. Only available if Postgres Pro was built with zlib.

Values:

0 - no compression

1 - ZIP compression

2 - ZLIB compression (= ZIP plus meta-data and block CRCs)

Default: 0

Applies to: pgp\_sym\_encrypt, pgp\_pub\_encrypt

#### **F.32.3.8.3. compress-level**

How much to compress. Higher levels compress smaller but are slower. 0 disables compression.

Values: 0, 1-9

Default: 6

Applies to: pgp\_sym\_encrypt, pgp\_pub\_encrypt

#### **F.32.3.8.4. convert-crlf**

Whether to convert `\n` into `\r\n` when encrypting and `\r\n` to `\n` when decrypting. RFC 4880 specifies that text data should be stored using `\r\n` line-feeds. Use this to get fully RFC-compliant behavior.

Values: 0, 1

Default: 0

Applies to: pgp\_sym\_encrypt, pgp\_pub\_encrypt, pgp\_sym\_decrypt, pgp\_pub\_decrypt

#### **F.32.3.8.5. disable-mdc**

Do not protect data with SHA-1. The only good reason to use this option is to achieve compatibility with ancient PGP products, predating the addition of SHA-1 protected packets to RFC 4880. Recent gnupg.org and pgp.com software supports it fine.

Values: 0, 1

Default: 0

Applies to: pgp\_sym\_encrypt, pgp\_pub\_encrypt

#### **F.32.3.8.6. sess-key**

Use separate session key. Public-key encryption always uses a separate session key; this option is for symmetric-key encryption, which by default uses the S2K key directly.

Values: 0, 1

Default: 0

Applies to: pgp\_sym\_encrypt

#### **F.32.3.8.7. s2k-mode**

Which S2K algorithm to use.

Values:

0 - Without salt. Dangerous!

1 - With salt but with fixed iteration count.

3 - Variable iteration count.

Default: 3

Applies to: pgp\_sym\_encrypt

**F.32.3.8.8. s2k-count**

The number of iterations of the S2K algorithm to use. It must be a value between 1024 and 65011712, inclusive.

Default: A random value between 65536 and 253952

Applies to: `pgp_sym_encrypt`, only with `s2k-mode=3`

**F.32.3.8.9. s2k-digest-algo**

Which digest algorithm to use in S2K calculation.

Values: `md5`, `sha1`

Default: `sha1`

Applies to: `pgp_sym_encrypt`

**F.32.3.8.10. s2k-cipher-algo**

Which cipher to use for encrypting separate session key.

Values: `bf`, `aes`, `aes128`, `aes192`, `aes256`

Default: `use cipher-algo`

Applies to: `pgp_sym_encrypt`

**F.32.3.8.11. unicode-mode**

Whether to convert textual data from database internal encoding to UTF-8 and back. If your database already is UTF-8, no conversion will be done, but the message will be tagged as UTF-8. Without this option it will not be.

Values: `0`, `1`

Default: `0`

Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`

**F.32.3.9. Generating PGP Keys with GnuPG**

To generate a new key:

```
gpg --gen-key
```

The preferred key type is “DSA and Elgamal”.

For RSA encryption you must create either DSA or RSA sign-only key as master and then add an RSA encryption subkey with `gpg --edit-key`.

To list keys:

```
gpg --list-secret-keys
```

To export a public key in ASCII-armor format:

```
gpg -a --export KEYID > public.key
```

To export a secret key in ASCII-armor format:

```
gpg -a --export-secret-keys KEYID > secret.key
```

You need to use `dearmor()` on these keys before giving them to the PGP functions. Or if you can handle binary data, you can drop `-a` from the command.

For more details see `man gpg`, *The GNU Privacy Handbook* and other documentation on <https://www.gnupg.org/>.

**F.32.3.10. Limitations of PGP Code**

- No support for signing. That also means that it is not checked whether the encryption subkey belongs to the master key.

- No support for encryption key as master key. As such practice is generally discouraged, this should not be a problem.
- No support for several subkeys. This may seem like a problem, as this is common practice. On the other hand, you should not use your regular GPG/PGP keys with `pgcrypto`, but create new ones, as the usage scenario is rather different.

### F.32.4. Raw Encryption Functions

These functions only run a cipher over data; they don't have any advanced features of PGP encryption. Therefore they have some major problems:

1. They use user key directly as cipher key.
2. They don't provide any integrity checking, to see if the encrypted data was modified.
3. They expect that users manage all encryption parameters themselves, even IV.
4. They don't handle text.

So, with the introduction of PGP encryption, usage of raw encryption functions is discouraged.

```
encrypt(data bytea, key bytea, type text) returns bytea
decrypt(data bytea, key bytea, type text) returns bytea
```

```
encrypt_iv(data bytea, key bytea, iv bytea, type text) returns bytea
decrypt_iv(data bytea, key bytea, iv bytea, type text) returns bytea
```

Encrypt/decrypt data using the cipher method specified by *type*. The syntax of the *type* string is:

```
algorithm [ - mode ] [ /pad: padding ]
```

where *algorithm* is one of:

- `bf` — Blowfish
- `aes` — AES (Rijndael-128, -192 or -256)

and *mode* is one of:

- `cbc` — next block depends on previous (default)
- `ecb` — each block is encrypted separately (for testing only)

and *padding* is one of:

- `pkcs` — data may be any length (default)
- `none` — data must be multiple of cipher block size

So, for example, these are equivalent:

```
encrypt(data, 'fooz', 'bf')
encrypt(data, 'fooz', 'bf-cbc/pad:pkcs')
```

In `encrypt_iv` and `decrypt_iv`, the *iv* parameter is the initial value for the CBC mode; it is ignored for ECB. It is clipped or padded with zeroes if not exactly block size. It defaults to all zeroes in the functions without this parameter.

### F.32.5. Random-Data Functions

```
gen_random_bytes(count integer) returns bytea
```

Returns *count* cryptographically strong random bytes. At most 1024 bytes can be extracted at a time. This is to avoid draining the randomness generator pool.

```
gen_random_uuid() returns uuid
```

Returns a version 4 (random) UUID. (Obsolete, this function is now also included in core PostgreSQL.)

## F.32.6. Notes

### F.32.6.1. Configuration

`pgcrypto` configures itself according to the findings of the main Postgres Pro `configure` script. The options that affect it are `--with-zlib` and `--with-openssl`.

When compiled with `zlib`, PGP encryption functions are able to compress data before encrypting.

When compiled with `OpenSSL`, there will be more algorithms available. Also public-key encryption functions will be faster as `OpenSSL` has more optimized `BIGNUM` functions.

**Table F.20. Summary of Functionality with and without OpenSSL**

Functionality	Built-in	With OpenSSL
MD5	yes	yes
SHA1	yes	yes
SHA224/256/384/512	yes	yes
Other digest algorithms	no	yes (Note 1)
Blowfish	yes	yes
AES	yes	yes
DES/3DES/CAST5	no	yes
Raw encryption	yes	yes
PGP Symmetric encryption	yes	yes
PGP Public-Key encryption	yes	yes

When compiled against `OpenSSL 3.0.0` and later versions, the legacy provider must be activated in the `openssl.cnf` configuration file in order to use older ciphers like `DES` or `Blowfish`.

Notes:

1. Any digest algorithm `OpenSSL` supports is automatically picked up. This is not possible with ciphers, which need to be supported explicitly.

### F.32.6.2. NULL Handling

As is standard in SQL, all functions return `NULL`, if any of the arguments are `NULL`. This may create security risks on careless usage.

### F.32.6.3. Security Limitations

All `pgcrypto` functions run inside the database server. That means that all the data and passwords move between `pgcrypto` and client applications in clear text. Thus you must:

1. Connect locally or use SSL connections.
2. Trust both system and database administrator.

If you cannot, then better do crypto inside client application.

The implementation does not resist *side-channel attacks*. For example, the time required for a `pgcrypto` decryption function to complete varies among ciphertexts of a given size.

## F.33. `pg_freemap`

The `pg_freemap` module provides a means for examining the free space map (FSM). It provides a function called `pg_freemap`, or two overloaded functions, to be precise. The functions show the value recorded in the free space map for a given page, or for all pages in the relation.

By default use is restricted to superusers and members of the `pg_stat_scan_tables` role. Access may be granted to others using `GRANT`.

### F.33.1. Functions

`pg_freespace(rel regclass IN, blkno bigint IN)` returns `int2`

Returns the amount of free space on the page of the relation, specified by `blkno`, according to the FSM.

`pg_freespace(rel regclass IN, blkno OUT bigint, avail OUT int2)`

Displays the amount of free space on each page of the relation, according to the FSM. A set of (`blkno bigint`, `avail int2`) tuples is returned, one tuple for each page in the relation.

The values stored in the free space map are not exact. They're rounded to precision of 1/256th of `BLCKSZ` (32 bytes with default `BLCKSZ`), and they're not kept fully up-to-date as tuples are inserted and updated.

For indexes, what is tracked is entirely-unused pages, rather than free space within pages. Therefore, the values are not meaningful, just whether a page is full or empty.

#### Note

The interface was changed in version 8.4, to reflect the new FSM implementation introduced in the same version.

### F.33.2. Sample Output

```
postgres=# SELECT * FROM pg_freespace('foo');
```

blkno	avail
0	0
1	0
2	0
3	32
4	704
5	704
6	704
7	1216
8	704
9	704
10	704
11	704
12	704
13	704
14	704
15	704
16	704
17	704
18	704
19	3648

(20 rows)

```
postgres=# SELECT * FROM pg_freespace('foo', 7);
```

pg_freespace
1216

(1 row)

## F.34. pg\_pathman

### Important

Starting from Postgres Pro 12, using `pg_pathman` is not recommended. Use vanilla declarative partitioning instead, as described in [Section 5.11](#).

The `pg_pathman` is a Postgres Pro extension that provides an optimized partitioning solution for large and distributed databases. Using `pg_pathman`, you can:

- Partition large databases without downtime.
- Speed up query execution for partitioned tables.
- Manage existing partitions and add new partitions on the fly.
- Add foreign tables as partitions.
- Join partitioned tables for read and write operations.

The extension is compatible with Postgres Pro 9.5 or higher.

### F.34.1. Installation and Setup

The `pg_pathman` extension is included into the Postgres Pro. Once you have Postgres Pro installed, complete the following steps to enable `pg_pathman`:

1. Add `pg_pathman` to the `shared_preload_libraries` variable in the `postgresql.conf` file:

```
shared_preload_libraries = 'pg_pathman'
```

### Important

`pg_pathman` may have conflicts with other extensions that use the same hook functions. For example, `pg_pathman` may interfere with the `pg_stat_statements` extension as they both use `ProcessUtility_hook`. To avoid such issues, `pg_pathman` must always be the last in the list of libraries: `shared_preload_libraries = 'pg_stat_statements, pg_pathman'`

2. Restart the Postgres Pro instance for the settings to take effect.
3. Create the `pg_pathman` extension as follows:

```
CREATE SCHEMA pathman;  
GRANT USAGE ON SCHEMA pathman TO PUBLIC;  
CREATE EXTENSION pg_pathman WITH SCHEMA pathman;
```

### Important

To ensure that your calls to `pg_pathman`'s functions are always secure against `search_path`-based attacks (see [CREATE EXTENSION](#) for details), install it only into a clean schema where nobody except superusers has the `CREATE` privilege for database objects.

Once `pg_pathman` is enabled, you can start partitioning tables.

**Note**

During installation, `pg_pathman` creates a few RLS policies to restrict access to its own tables. Postgres Pro core, however, does not support dump/restore of databases where extensions issuing `CREATE POLICY` statements are installed. Therefore, when restoring a dump of a database where `pg_pathman` is installed, you will get error messages such as:

```
ERROR: policy "allow_select" for table "pathman_config" already exists
```

Ignore them since they do not affect whether the data being restored is complete.

**Tip**

You can also build `pg_pathman` from source code by executing the following command in the `pg_pathman` directory:

```
make install USE_PGXS=1
```

When this operation is complete, follow the steps described above to complete the setup.

In addition, do not forget to set the `PG_CONFIG` variable if you want to test `pg_pathman` on a custom build of Postgres Pro. For details, see [Building and Installing PostgreSQL Extension Modules](#).

You can toggle `pg_pathman` or its specific custom nodes on and off using GUC variables. For details, see [Section F.34.5.1](#).

If you want to permanently disable `pg_pathman` for a previously partitioned table, use the `disable_pathman_for()` function:

```
SELECT disable_pathman_for('range_rel');
```

All sections and data will remain unchanged and will be handled by the standard Postgres Pro inheritance mechanism.

**F.34.1.1. Updating `pg_pathman`**

If you already have a previous version of `pg_pathman` installed, complete the following steps to upgrade to a newer version:

1. Install Postgres Pro.
2. Restart your Postgres Pro cluster.
3. If you are running a previous major version of `pg_pathman` (the second digit in the version number is different), complete the update as follows:

```
ALTER EXTENSION pg_pathman UPDATE TO version;  
SET pg_pathman.enable = t;
```

where *version* is the `pg_pathman` major version number, such as 1.5.

You can check the current `pg_pathman` version by running the `pathman_version()` function.

**F.34.2. Usage**

[Choosing Partitioning Strategies](#)

[Running Non-Blocking Data Migration](#)

[Partitioning by a Single Expression](#)

## Partitioning by Composite Key

## Running Multilevel Partitioning

## Managing Partitions

As your database grows, indexing mechanisms may become inefficient and cause high latency as you run queries. To improve performance, ensure scalability, and optimize database administration processes you can use partitioning — splitting a large table into smaller pieces, with each row moved to a single partition according to the partitioning key.

Traditionally, Postgres Pro has supported partitioning via table inheritance, with each partition created as a child table with a CHECK constraint. In Postgres Pro 10, support for [declarative partitioning](#) was added, which also relies on inheritance. With these approaches, the query planner has to perform an exhaustive search and check constraints on each partition to build a query plan, which may slow down queries for tables with a large number of partitions. The `pg_pathman` extension uses an optimized planning algorithms and partitioning functions based on the internal structure of the partitioned tables, which allows to achieve better performance results. For details on `pg_pathman` implementation specifics, see [Section F.34.4](#).

### F.34.2.1. Choosing Partitioning Strategies

The `pg_pathman` extension supports the following partitioning strategies:

- Hash — maps rows to partitions using a generic hash function. Choose this strategy if most of your queries will be of the exact-match type.
- Range — maps rows to partitions based on partitioning key ranges assigned to each partition. Choose this strategy if your database contains numeric data that you are likely to query or manage by ranges. For example, you may want to query historical data by years, or review experiment results by specific numeric ranges. To achieve performance gains, `pg_pathman` uses the binary search algorithm.

By default, `pg_pathman` migrates all data from the parent table to the newly created partitions at once (*blocking partitioning*). This approach enables you to restructure the table in a single transaction, but may cause downtime if you have a lot of data. If it is critical to avoid downtime, you can use *concurrent partitioning*. In this case, `pg_pathman` writes all the updates to the newly created partitions, but keeps the original data in the parent table until you explicitly migrate it. This enables you to partition large databases without downtime, as you can choose convenient time for migration and copy data in small batches without blocking other transactions. For details on concurrent partitioning, see [Section F.34.2.2](#).

#### F.34.2.1.1. Setting up Hash Partitioning

To perform hash partitioning with `pg_pathman`, run the `create_hash_partitions()` function:

```
create_hash_partitions(parent_relid      REGCLASS,
                      expression        TEXT,
                      partitions_count  INTEGER,
                      partition_data    BOOLEAN DEFAULT TRUE,
                      partition_names   TEXT[]  DEFAULT NULL,
                      tablespaces       TEXT[]  DEFAULT NULL)
```

The `pg_pathman` module creates the specified number of partitions based on the hash function. Optionally, you can specify partition names and tablespaces by setting `partition_names` and `tablespaces` options, respectively.

You cannot add or remove partitions after the parent table is split. If required, you can replace the specified partition with another table:

```
replace_hash_partition(old_partition    REGCLASS,
                      new_partition     REGCLASS,
                      lock_parent       BOOL DEFAULT TRUE);
```

When set to `true`, `lock_parent` parameter will prevent any `INSERT/UPDATE/ALTER TABLE` queries to parent table.

If you omit the optional `partition_data` parameter or set it to `true`, all the data from the parent table gets migrated to partitions. The `pg_pathman` module blocks the table for other transactions until data migration completes. To avoid downtime, you can set the `partition_data` parameter to `false` and later use the `partition_table_concurrently()` function to migrate your data to partitions without blocking other queries. For details, see the [Section F.34.2.2](#).

#### F.34.2.1.2. Setting up Range Partitioning

The `pg_pathman` module provides the `create_range_partitions()` for range partitioning. This function creates partitions based on the specified interval and the initial partitioning key value. New partitions are created automatically when you insert data outside of the already covered range.

```
create_range_partitions(parent_relid REGCLASS,
                       expression   TEXT,
                       start_value  ANYELEMENT,
                       p_interval   ANYELEMENT | INTERVAL,
                       p_count      INTEGER DEFAULT NULL,
                       partition_data BOOLEAN DEFAULT TRUE)
```

The `pg_pathman` module creates partitions based on the specified parameters. If you omit the optional `p_count` parameter, `pg_pathman` calculates the required number of partitions based on the specified start value and interval. If you insert new data outside of the existing partition range, `pg_pathman` creates new partitions automatically, keeping the specified interval. This approach ensures that all partitions are of the same size, which can improve query performance and facilitate database management.

Alternatively, you can specify an array defining the bounds of partitions to be created using the `bounds` parameter:

```
create_range_partitions(parent_relid REGCLASS,
                       expression   TEXT,
                       bounds       ANYARRAY,
                       partition_names TEXT[] DEFAULT NULL,
                       tablespaces  TEXT[] DEFAULT NULL,
                       partition_data BOOLEAN DEFAULT TRUE)
```

If required, you can also use [partition management functions](#) to add partitions manually. For example, if there is a gap between the created partitions, `pg_pathman` cannot fill it with a new partition in an automated mode.

By default, all the data from the parent table gets migrated to the specified number of partitions. The `pg_pathman` module blocks the table for other transactions until data migration completes. To avoid downtime, you can set the `partition_data` parameter to `false` and later use the `partition_table_concurrently()` function to migrate your data to partitions without blocking other queries. For details, see the [Section F.34.2.2](#).

#### F.34.2.2. Running Non-Blocking Data Migration

If it is critical to avoid downtime, you can perform concurrent partitioning by setting the `partition_data` parameter of the partitioning function to `false`. In this case, `pg_pathman` creates empty partitions, keeping all the original data in the parent table. At the same time, all the database updates are written to the newly created partitions. You can later migrate the original data to partitions without blocking other queries using the `partition_table_concurrently()` function:

```
partition_table_concurrently(relation REGCLASS,
                             batch_size INTEGER DEFAULT 1000,
                             sleep_time FLOAT8 DEFAULT 1.0)
```

where:

- `relation` is the parent table.
- `batch_size` is the number of rows to copy from the parent table to partitions at a time. You can set this parameter to any integer value from 1 to 10000.
- `sleep_time` is the time interval between migration attempts, in seconds.

The `pg_pathman` module starts a background worker to move the data from the parent table to partitions in small batches of the specified `batch_size`. If one or more rows in the batch are locked by other queries, `pg_pathman` waits for the specified `sleep_time` and tries again, up to 60 times. You can monitor the migration process in the `pathman_concurrent_part_tasks` view that shows the number of rows migrated so far:

```
[user]postgres: select * from pathman_concurrent_part_tasks ;
userid | pid | dbid | relid | processed | status
-----+-----+-----+-----+-----+-----
user   | 20012 | 12413 | test | 334000 | working
(1 row)
```

If you need to stop data migration, run the `stop_concurrent_part_task()` function at any time:

```
SELECT stop_concurrent_part_task(relation REGCLASS);
```

`pg_pathman` completes the migration of the current batch and terminates the migration process.

### Tip

When `pg_pathman` migrates all the data from the parent table, you can exclude the parent table from the query plan. See the `set_enable_parent()` function description for details.

## F.34.2.3. Partitioning by a Single Expression

For both range and hash partitioning strategies, `pg_pathman` supports partitioning by expression that returns a single scalar value. The partitioning expression can reference a table column, as well as calculate the partitioning key based on one or more column values.

### Tip

If you would like to partition a table by a tuple, see [Section F.34.2.4](#).

To partition a table by expression, use `pg_pathman` [partitioning functions](#). The partitioning expression must satisfy the following conditions:

- Expression must reference at least one column of the partitioned table.
- All referenced columns must be marked as `NOT NULL`.
- Expression cannot reference system attributes, such as `oid`, `xmin`, `xmax`, etc.
- Expression cannot include subqueries.
- All functions used by expression must be marked as `IMMUTABLE`.

As the expression can return a value of virtually any type, make sure to convert it to the type you need for partitioning.

To access a partition, you must use the exact expression used for partitioning. Otherwise, `pg_pathman` cannot optimize the query. You can view the partitioning expression for each partitioned table in the `pathman_config` table.

### F.34.2.3.1. Examples

Suppose you have the `test` table that stores some `jsonb` data:

```
CREATE TABLE test(col jsonb NOT NULL);
INSERT INTO test
SELECT format('{"key": %s, "date": "%s", "value": "%s"}',
             i, current_date, md5(i::text))::jsonb
FROM generate_series(1, 10000 * 10) as g(i);
```

To partition this data by range of the key value, you need to extract this value from the jsonb object and convert it to a numeric type, such as bigint:

```
SELECT create_range_partitions('test', '(col->>'key')::bigint', 1, 10000, 10);
```

pg\_pathman splits the parent table into ten partitions, with each partition storing 10000 rows:

```
SELECT * FROM pathman_partition_list;
parent | partition | parttype | expr | range_min |
range_max
-----+-----+-----+-----+-----+-----
+-----+
test   | test_1    | 2        | ((col ->> 'key')::bigint) | 1          | 10001
test   | test_2    | 2        | ((col ->> 'key')::bigint) | 10001      | 20001
test   | test_3    | 2        | ((col ->> 'key')::bigint) | 20001      | 30001
test   | test_4    | 2        | ((col ->> 'key')::bigint) | 30001      | 40001
test   | test_5    | 2        | ((col ->> 'key')::bigint) | 40001      | 50001
test   | test_6    | 2        | ((col ->> 'key')::bigint) | 50001      | 60001
test   | test_7    | 2        | ((col ->> 'key')::bigint) | 60001      | 70001
test   | test_8    | 2        | ((col ->> 'key')::bigint) | 70001      | 80001
test   | test_9    | 2        | ((col ->> 'key')::bigint) | 80001      | 90001
test   | test_10   | 2        | ((col ->> 'key')::bigint) | 90001      | 100001
(10 rows)
```

### F.34.2.4. Partitioning by Composite Key

Using pg\_pathman, you can also perform range partitioning by composite key. A composite key consists of two or more comma-separated values, which can be columns or expressions extracting the values from the table. The expressions defining the composite key must satisfy the conditions described in [Section F.34.2.3](#).

Although pg\_pathman does not support automatic partition creation by composite key, you can add partitions using the add\_range\_partition() function. A typical workflow is as follows:

1. Enable automatic partition naming for your table by running the create\_naming\_sequence() function.
2. Create a composite partitioning key.
3. Register a table you are going to partition with pg\_pathman using the add\_to\_pathman\_config() function.
4. Add a partition based on the defined composite partitioning key using the add\_range\_partition() function.

#### F.34.2.4.1. Examples

Suppose you have the test table that stores some temporal data:

```
CREATE TABLE test (logdate date NOT NULL, comment text);
```

To partition this data by month and year, you have to create a composite key:

```
CREATE TYPE test_key AS (year float8, month float8);
```

To enable automatic partition naming, run the create\_naming\_sequence() function passing the table name as an argument:

```
SELECT create_naming_sequence('test');
```

Register the test table with `pg_pathman`, specifying the partitioning key you are going to use:

```
SELECT add_to_pathman_config('test',
                             '( extract(year from logdate),
                               extract(month from logdate) )::test_key',
                             NULL);
```

Create a partition that includes all the data in the range of ten years, starting from January of the current year:

```
SELECT add_range_partition('test',
                           (extract(year from current_date), 1)::test_key,
                           (extract(year from current_date + '10 years'::interval),
                            1)::test_key);
```

### F.34.2.5. Running Multilevel Partitioning

`pg_pathman` supports multilevel partitioning for both hash and range partitioning strategies. You can use partitioning strategies in any combination: a hash- or range-partitioned table can be further partitioned by both hash or range.

To split an existing partition into several child ones, use the regular `pg_pathman` partitioning functions as explained in [Section F.34.2.1](#), passing the name of the partition to be split as the `parent_relid` parameter. You can check the exact partition names in the `pathman_partition_list` view.

When opting for the range-range partitioning combination, you can either choose a different partitioning expression, or use the same expression as for the parent table. In the latter case, if the selected range is larger than that of the parent partition, only those child partitions that intersect with the parent range will be in use. Other child partitions will remain empty unless their parent is merged with an adjacent partition that covers at least a part of their range.

#### F.34.2.5.1. Examples

Suppose you have the `journal` table with some logs, which is partitioned by month:

```
-- create an empty table
CREATE TABLE journal (
id      SERIAL,
dt      TIMESTAMP NOT NULL,
level   INTEGER,
msg     TEXT);

-- generate some log data into the table
INSERT INTO journal (dt, level, msg)
SELECT g, random() * 6, md5(g::text)
FROM generate_series('2015-01-01'::date, '2015-12-31'::date, '1 minute') as g;

-- partition the table by range
SELECT create_range_partitions('journal', 'dt', '2015-01-01'::date, '1
month'::interval);
```

If having smaller partitions makes more sense at some point, you can further split the partitions by hash or range. For example, to split the `journal_1` partition into subpartitions by day, run:

```
SELECT create_range_partitions('journal_1', 'dt', '2015-01-01'::date, '1
day'::interval);
```

Similarly, you can use hash partitioning to create child partitions. For example, split the `journal_2` partition into five partitions by hash using the `id` column as the partitioning key:

```
SELECT create_hash_partitions('journal_2', 'id', '5');
```

### F.34.2.6. Managing Partitions

`pg_pathman` provides multiple functions for easy partition management. For details, see [Section F.34.5.3.4](#).

## F.34.3. Examples

### F.34.3.1. Common Tips

- You can add `partition` column containing the names of the underlying partitions using the system attribute called `tableoid`:

```
SELECT tableoid::regclass AS partition, * FROM partitioned_table;
```

- Though indices on a parent table are not particularly useful (since the parent table is supposed to be empty), they act as prototypes for indices on partitions. For each index on the parent table, `pg_pathman` creates a similar index on each partition.
- All running concurrent partitioning tasks can be listed using the `pathman_concurrent_part_tasks` view:

```
SELECT * FROM pathman_concurrent_part_tasks;
userid | pid | dbid | relid | processed | status
-----+-----+-----+-----+-----+-----
user   | 7367 | 16384 | test  | 472000 | working
(1 row)
```

- The `pathman_partition_list` in conjunction with `drop_range_partition()` can be used to drop range partitions in a more flexible way compared to `DROP TABLE`:

```
SELECT drop_range_partition(partition, false) /* move data to parent */
FROM pathman_partition_list
WHERE parent = 'part_test'::regclass AND range_min::int < 500;
NOTICE:  1 rows copied from part_test_11
NOTICE: 100 rows copied from part_test_1
NOTICE: 100 rows copied from part_test_2
drop_range_partition
-----
dummy_test_11
dummy_test_1
dummy_test_2
(3 rows)
```

- You can turn foreign tables into partitions using the `attach_range_partition()` function. Rows that were meant to be inserted into the parent will be redirected to foreign partitions using `PartitionFilter`. By default, it is only allowed to insert rows into partitions provided by `postgres_fdw`. This setting is controlled by the `pg_pathman.insert_into_fdw` variable. You must have superuser rights to change this setting.

### F.34.3.2. Hash Partitioning

Consider an example of hash partitioning. First create a table with an integer column:

```
CREATE TABLE items (
id          SERIAL PRIMARY KEY,
name       TEXT,
code       BIGINT);

INSERT INTO items (id, name, code)
SELECT g, md5(g::text), random() * 100000
FROM generate_series(1, 100000) as g;
```

Now run the `create_hash_partitions()` function with appropriate arguments:

```
SELECT create_hash_partitions('items', 'id', 100);
```

This will create new partitions and move the data from the parent table to partitions.

Here is an example of the query performing filtering by partitioning key:

```
SELECT * FROM items WHERE id = 1234;
 id | name | code
-----+-----+-----
 1234 | 81dc9bdb52d04dc20036dbd8313ed055 | 1855
(1 row)
```

```
EXPLAIN SELECT * FROM items WHERE id = 1234;
QUERY PLAN
```

```
-----
Append (cost=0.28..8.29 rows=0 width=0)
->  Index Scan using items_34_pkey on items_34 (cost=0.28..8.29 rows=0 width=0)
    Index Cond: (id = 1234)
```

Notice that the Append node contains only one child scan, which corresponds to the WHERE clause.

### Important

Pay attention to the fact that `pg_pathman` excludes the parent table from the query plan.

To access the parent table, use the ONLY modifier:

```
EXPLAIN SELECT * FROM ONLY items;
QUERY PLAN
```

```
-----
Seq Scan on items (cost=0.00..0.00 rows=1 width=45)
```

### F.34.3.3. Range Partitioning

Consider an example of range partitioning. Let's create a table containing some dummy logs:

```
CREATE TABLE journal (
id SERIAL,
dt TIMESTAMP NOT NULL,
level INTEGER,
msg TEXT);
```

```
-- similar index will also be created for each partition
CREATE INDEX ON journal(dt);
```

```
-- generate some data
INSERT INTO journal (dt, level, msg)
SELECT g, random() * 6, md5(g::text)
FROM generate_series('2015-01-01'::date, '2015-12-31'::date, '1 minute') as g;
```

Run the `create_range_partitions()` function to create partitions so that each partition would contain the data for one day:

```
SELECT create_range_partitions('journal', 'dt', '2015-01-01'::date, '1 day'::interval);
```

It will create 364 partitions and move the data from the parent table to partitions.

New partitions are appended automatically by insert trigger, but it can be done manually with the following functions:

```
-- add new partition with specified range
```

```
SELECT add_range_partition('journal', '2016-01-01'::date, '2016-01-07'::date);

-- append new partition with default range
SELECT append_range_partition('journal');
```

The first one creates a partition with specified range. The second one creates a partition with default interval and appends it to the partition list. It is also possible to attach an existing table as partition. For example, we may want to attach an archive table (or even foreign table from another server) for some outdated data:

```
CREATE FOREIGN TABLE journal_archive (
id      INTEGER NOT NULL,
dt      TIMESTAMP NOT NULL,
level   INTEGER,
msg     TEXT)
SERVER archive_server;

SELECT attach_range_partition('journal', 'journal_archive', '2014-01-01'::date,
'2015-01-01'::date);
```

### Important

The attached table must have the same columns as the partitioned table, except for the dropped columns. The attached columns must have the same type, collation, and NOT NULL settings as the original columns.

To merge two adjacent partitions, use the `merge_range_partitions()` function:

```
SELECT merge_range_partitions('journal_archive', 'journal_1');
```

To split partition by value, use the `split_range_partition()` function:

```
SELECT split_range_partition('journal_366', '2016-01-03'::date);
```

To detach partition, use the `detach_range_partition()` function:

```
SELECT detach_range_partition('journal_archive');
```

Here is an example of the query performing filtering by partitioning key:

```
SELECT * FROM journal WHERE dt >= '2015-06-01' AND dt < '2015-06-03';
id      |          dt          | level |          msg
-----+-----+-----+-----
217441  | 2015-06-01 00:00:00 |     2 | 15053892d993ce19f580a128f87e3dbf
217442  | 2015-06-01 00:01:00 |     1 | 3a7c46f18a952d62ce5418ac2056010c
217443  | 2015-06-01 00:02:00 |     0 | 92c8de8f82faf0b139a3d99f2792311d
...
(2880 rows)
```

```
EXPLAIN SELECT * FROM journal WHERE dt >= '2015-06-01' AND dt < '2015-06-03';
QUERY PLAN
```

```
-----
Append  (cost=0.00..58.80 rows=0 width=0)
->  Seq Scan on journal_152  (cost=0.00..29.40 rows=0 width=0)
->  Seq Scan on journal_153  (cost=0.00..29.40 rows=0 width=0)
(3 rows)
```

## F.34.4. Internals

`pg_pathman` stores partitioning configuration in the `pathman_config` table; each row contains a single entry for a partitioned table (relation name, partitioning column and its type). During the initialization

stage the `pg_pathman` module caches some information about child partitions in the shared memory, which is used later for plan construction. Before a `SELECT` query is executed, `pg_pathman` traverses the condition tree in search of expressions like:

```
VARIABLE OP CONST
```

where `VARIABLE` is a partitioning key, `OP` is a comparison operator (supported operators are `=`, `<`, `<=`, `>`, `>=`), `CONST` is a scalar value. For example:

```
WHERE id = 150
```

Based on the partitioning type and condition's operator, `pg_pathman` searches for the corresponding partitions and builds the plan.

### F.34.4.1. Custom Plan Nodes

`pg_pathman` provides a couple of *custom plan nodes* which aim to reduce execution time, namely:

- `RuntimeAppend` (overrides `Append` plan node)
- `RuntimeMergeAppend` (overrides `MergeAppend` plan node)
- `PartitionFilter` (drop-in replacement for `INSERT` triggers)
- `PartitionRouter` for cross-partition `UPDATE` queries instead of triggers

`PartitionFilter` acts as a *proxy node* for `INSERT`'s child scan, which means it can redirect output tuples to the corresponding partition:

```
EXPLAIN (COSTS OFF)
INSERT INTO partitioned_table
SELECT generate_series(1, 10), random();
      QUERY PLAN
```

```
-----
Insert on partitioned_table
-> Custom Scan (PartitionFilter)
    -> Subquery Scan on "*SELECT*"
        -> Result
(4 rows)
```

`PartitionRouter` is another proxy node used in conjunction with `PartitionFilter` to enable cross-partition `UPDATE` operations, for example, when you update any column of a partitioning key.

### Important

The `PartitionRouter` node transforms cross-partition `UPDATE` commands into `DELETE + INSERT`. On Postgres Pro versions prior to 11, this operation is unsafe as `pg_pathman` cannot determine whether the updated row has been deleted or moved to another partition.

By default, `PartitionRouter` is disabled to avoid undesirable side effects. To enable this node, set the `pg_pathman.enable_partitionrouter` to on.

```
EXPLAIN (COSTS OFF)
UPDATE partitioned_table
SET value = value + 1 WHERE value = 2;
      QUERY PLAN
```

```
-----
Update on partitioned_table_0
-> Custom Scan (PartitionRouter)
    -> Custom Scan (PartitionFilter)
        -> Seq Scan on partitioned_table_0
            Filter: (value = 2)
```

(5 rows)

RuntimeAppend and RuntimeMergeAppend have much in common: they come in handy in a case when WHERE condition takes form of:

VARIABLE OP PARAM

This kind of expressions can no longer be optimized at planning time since the parameter's value is not known until the execution stage takes place. The problem can be solved by embedding the *WHERE condition analysis routine* into the original Append's code, thus making it pick only required scans out of a whole bunch of planned partition scans. This effectively boils down to creation of a custom node capable of performing such a check.

There are at least several cases that demonstrate usefulness of these nodes:

```
/* create table we're going to partition */
CREATE TABLE partitioned_table(id INT NOT NULL, payload REAL);

/* insert some data */
INSERT INTO partitioned_table
SELECT generate_series(1, 1000), random();

/* perform partitioning */
SELECT create_hash_partitions('partitioned_table', 'id', 100);

/* create ordinary table */
CREATE TABLE some_table AS SELECT generate_series(1, 100) AS VAL;
```

- id = (select ... limit 1)

```
EXPLAIN (COSTS OFF, ANALYZE) SELECT * FROM partitioned_table
WHERE id = (SELECT * FROM some_table LIMIT 1);
                                QUERY PLAN
```

```
-----
Custom Scan (RuntimeAppend) (actual time=0.030..0.033 rows=1 loops=1)
  InitPlan 1 (returns $0)
    -> Limit (actual time=0.011..0.011 rows=1 loops=1)
          -> Seq Scan on some_table (actual time=0.010..0.010 rows=1 loops=1)
    -> Seq Scan on partitioned_table_70 partitioned_table (actual time=0.004..0.006
rows=1 loops=1)
      Filter: (id = $0)
      Rows Removed by Filter: 9
Planning time: 1.131 ms
Execution time: 0.075 ms
(9 rows)
```

```
/* disable RuntimeAppend node */
SET pg_pathman.enable_runtimeappend = f;
```

```
EXPLAIN (COSTS OFF, ANALYZE) SELECT * FROM partitioned_table
WHERE id = (SELECT * FROM some_table LIMIT 1);
                                QUERY PLAN
```

```
-----
Append (actual time=0.196..0.274 rows=1 loops=1)
  InitPlan 1 (returns $0)
    -> Limit (actual time=0.005..0.005 rows=1 loops=1)
          -> Seq Scan on some_table (actual time=0.003..0.003 rows=1 loops=1)
    -> Seq Scan on partitioned_table_0 (actual time=0.014..0.014 rows=0 loops=1)
      Filter: (id = $0)
      Rows Removed by Filter: 6
```

```

-> Seq Scan on partitioned_table_1 (actual time=0.003..0.003 rows=0 loops=1)
    Filter: (id = $0)
    Rows Removed by Filter: 5
    ... /* more plans follow */
Planning time: 1.140 ms
Execution time: 0.855 ms
(306 rows)

```

- `id = ANY (select ...)`

```

EXPLAIN (COSTS OFF, ANALYZE) SELECT * FROM partitioned_table
WHERE id = any (SELECT * FROM some_table limit 4);
                                QUERY PLAN
-----

```

```

Nested Loop (actual time=0.025..0.060 rows=4 loops=1)
-> Limit (actual time=0.009..0.011 rows=4 loops=1)
    -> Seq Scan on some_table (actual time=0.008..0.010 rows=4 loops=1)
    -> Custom Scan (RuntimeAppend) (actual time=0.002..0.004 rows=1 loops=4)
        -> Seq Scan on partitioned_table_70 partitioned_table (actual
time=0.001..0.001 rows=10 loops=1)
            -> Seq Scan on partitioned_table_26 partitioned_table (actual
time=0.002..0.003 rows=9 loops=1)
                -> Seq Scan on partitioned_table_27 partitioned_table (actual
time=0.001..0.002 rows=20 loops=1)
                    -> Seq Scan on partitioned_table_63 partitioned_table (actual
time=0.001..0.002 rows=9 loops=1)
Planning time: 0.771 ms
Execution time: 0.101 ms
(10 rows)

```

```

/* disable RuntimeAppend node */
SET pg_pathman.enable_runtimeappend = f;

```

```

EXPLAIN (COSTS OFF, ANALYZE) SELECT * FROM partitioned_table
WHERE id = any (SELECT * FROM some_table limit 4);
                                QUERY PLAN
-----

```

```

Nested Loop Semi Join (actual time=0.531..1.526 rows=4 loops=1)
  Join Filter: (partitioned_table.id = some_table.val)
  Rows Removed by Join Filter: 3990
-> Append (actual time=0.190..0.470 rows=1000 loops=1)
    -> Seq Scan on partitioned_table (actual time=0.187..0.187 rows=0 loops=1)
    -> Seq Scan on partitioned_table_0 (actual time=0.002..0.004 rows=6
loops=1)
    -> Seq Scan on partitioned_table_1 (actual time=0.001..0.001 rows=5
loops=1)
    -> Seq Scan on partitioned_table_2 (actual time=0.002..0.004 rows=14
loops=1)
... /* 96 scans follow */
    -> Materialize (actual time=0.000..0.000 rows=4 loops=1000)
        -> Limit (actual time=0.005..0.006 rows=4 loops=1)
            -> Seq Scan on some_table (actual time=0.003..0.004 rows=4 loops=1)
Planning time: 2.169 ms
Execution time: 2.059 ms
(110 rows)

```

- NestLoop **involving a partitioned table**, which is omitted since it's occasionally shown above.

To learn more about custom nodes, see Alexander Korotkov's [blog](#).

## F.34.5. Reference

### F.34.5.1. GUC Variables

There are several user-accessible **GUC** variables designed to toggle `pg_pathman` or its specific custom nodes on and off.

- `pg_pathman.enable` — enable/disable the `pg_pathman` module.

Default: on

- `pg_pathman.enable_runtimeappend` — toggle the `RuntimeAppend` custom node on/off.

Default: on

- `pg_pathman.enable_runtimemergeappend` — toggle the `RuntimeMergeAppend` custom node on/off.

Default: on

- `pg_pathman.enable_partitionfilter` — toggle the `PartitionFilter` custom node on/off to enable/disable cross-partition `INSERT` operations.

Default: on

- `pg_pathman.enable_partitionrouter` — toggle the `PartitionRouter` custom node on/off to enable/disable cross-partition `UPDATE` operations.

Default: off

- `pg_pathman.enable_auto_partition` — toggle automatic partition creation on/off (per session).

Default: on

- `pg_pathman.enable_bounds_cache` — toggle bounds cache on/off.

Default: on

- `pg_pathman.insert_into_fdw` — allow `INSERT` operations into various foreign-data wrappers. Possible values: `disabled`, `postgres`, and `any_fdw`.

Default: `postgres`

- `pg_pathman.override_copy` — toggle `COPY` statement hooking on/off.

Default: on

### F.34.5.2. Views and Tables

#### F.34.5.2.1. `pathman_config`

This table stores the list of partitioned tables. This is the main configuration storage.

```
CREATE TABLE IF NOT EXISTS pathman_config (  
    partrel          REGCLASS NOT NULL PRIMARY KEY,  
    attname          TEXT NOT NULL,  
    parttype         INTEGER NOT NULL,  
    range_interval  TEXT);
```

#### F.34.5.2.2. `pathman_config_params`

This table stores optional parameters that override standard `pg_pathman` behavior.

```
CREATE TABLE IF NOT EXISTS pathman_config_params (  
    partrel          REGCLASS NOT NULL PRIMARY KEY,  
    enable_parent    BOOLEAN NOT NULL DEFAULT TRUE,  
    auto             BOOLEAN NOT NULL DEFAULT TRUE,  
    init_callback    REGPROCEDURE NOT NULL DEFAULT 0,  
    spawn_using_bgw  BOOLEAN NOT NULL DEFAULT FALSE);
```

**F.34.5.2.3. pathman\_concurrent\_part\_tasks**

This view lists all currently running concurrent partitioning tasks.

```
-- helper SRF function
CREATE OR REPLACE FUNCTION show_concurrent_part_tasks()
RETURNS TABLE (
    userid      REGROLE,
    pid         INT,
    dbid        OID,
    relid       REGCLASS,
    processed   INT,
    status      TEXT)
AS 'pg_pathman', 'show_concurrent_part_tasks_internal'
LANGUAGE C STRICT;

CREATE OR REPLACE VIEW pathman_concurrent_part_tasks
AS SELECT * FROM show_concurrent_part_tasks();
```

**F.34.5.2.4. pathman\_partition\_list**

This view lists all existing partitions, as well as their parents and range boundaries (NULL for hash partitions).

```
-- helper SRF function
CREATE OR REPLACE FUNCTION show_partition_list()
RETURNS TABLE (
    parent      REGCLASS,
    partition   REGCLASS,
    parttype    INT4,
    expr        TEXT,
    range_min   TEXT,
    range_max   TEXT)
AS 'pg_pathman', 'show_partition_list_internal'
LANGUAGE C STRICT;

CREATE OR REPLACE VIEW pathman_partition_list
AS SELECT * FROM show_partition_list();
```

**F.34.5.3. Functions****F.34.5.3.1. Partitioning Functions**

```
create_hash_partitions(parent_relid      REGCLASS,
                      expression        TEXT,
                      partitions_count  INTEGER,
                      partition_data    BOOLEAN DEFAULT TRUE,
                      partition_names   TEXT[] DEFAULT NULL,
                      tablespaces      TEXT[] DEFAULT NULL)
```

Performs hash partitioning for relation by integer key expression. The `partitions_count` parameter specifies the number of partitions to create; it cannot be changed afterwards. If `partition_data` is true, all the data will be automatically migrated from the parent table to partitions. Note that data migration may take a while to finish and the table will be locked until transaction commits. See `partition_table_concurrently()` for a lock-free way to migrate data. Partition creation callback is invoked for each partition if set beforehand (see `set_init_callback()`).

```
create_range_partitions(relation        REGCLASS,
                      expression        TEXT,
                      start_value       ANYELEMENT,
                      p_interval       ANYELEMENT,
```

```

p_count          INTEGER DEFAULT NULL,
partition_data   BOOLEAN DEFAULT TRUE)

```

```

create_range_partitions(relation      REGCLASS,
                        expression     TEXT,
                        start_value    ANYELEMENT,
                        p_interval     INTERVAL,
                        p_count        INTEGER DEFAULT NULL,
                        partition_data  BOOLEAN DEFAULT TRUE)

```

```

create_range_partitions(relation      REGCLASS,
                        expression     TEXT,
                        bounds         ANYARRAY,
                        partition_names TEXT[] DEFAULT NULL,
                        tablespaces    TEXT[] DEFAULT NULL,
                        partition_data  BOOLEAN DEFAULT TRUE)

```

Performs range partitioning for `relation` by partitioning key defined by `expression`. The `start_value` argument specifies the initial value, `p_interval` sets the default range for automatically created partitions or partitions created with `append_range_partition()` or `prepend_range_partition()`. If `p_interval` is set to `NULL`, automatic partition creation is disabled. `p_count` is the number of premade partitions. If `p_count` is not set, than `pg_pathman` tries to determine the number of partitions based on the `expression` value. The `bounds` array defines the bounds for partitions to be created. You can build this array using the `generate_range_bounds()` function. Partition creation callback is invoked for each partition if set beforehand.

#### F.34.5.3.2. Data Migration Functions

```

partition_table_concurrently(relation REGCLASS,
                             batch_size INTEGER DEFAULT 1000,
                             sleep_time FLOAT8 DEFAULT 1.0)

```

Starts a background worker to move data from parent table to partitions. The worker utilizes short transactions to copy small batches of data (up to 10K rows per transaction) and thus doesn't significantly interfere with user's activity.

```

stop_concurrent_part_task(relation REGCLASS)

```

Stops a background worker performing a concurrent partitioning task. Note: worker will exit after it finishes relocating a current batch.

#### F.34.5.3.3. Triggers

Triggers are no longer required for `INSERT` and cross-partition `UPDATE` operations. However, user-supplied triggers are supported:

- Each inserted row results in execution of `BEFORE/AFTER INSERT` trigger functions of a corresponding partition.
- Each updated row results in execution of `BEFORE/AFTER UPDATE` trigger functions of a corresponding partition.
- Each moved row (cross-partition update) results in execution of `BEFORE UPDATE + BEFORE/AFTER DELETE + BEFORE/AFTER INSERT` trigger functions of corresponding partitions.

#### F.34.5.3.4. Partition Management Functions

```

replace_hash_partition(old_partition  REGCLASS,
                       new_partition  REGCLASS,
                       lock_parent    BOOLEAN DEFAULT TRUE)

```

Replaces the specified partition of hash-partitioned table with another table. When set to `true`, the `lock_parent` parameter prevents any `INSERT/UPDATE/ALTER TABLE` queries to the parent table.

```
split_range_partition(partition_relid REGCLASS,
                    split_value ANYELEMENT,
                    partition_name TEXT DEFAULT NULL,
                    tablespace TEXT DEFAULT NULL)
```

Split range partition in two by value, with the specified value included into the second partition. Partition creation callback is invoked for a new partition if available.

```
merge_range_partitions(variadic partitions REGCLASS[])
```

Merge several adjacent range partitions. Partitions are automatically ordered by increasing bounds. All the data will be accumulated in the first partition, while other merged partitions are removed. If the remaining partition has any child partitions, new child partitions for the merged data will be created as required using the same partitioning expression.

```
append_range_partition(parent_relid REGCLASS,
                    partition_name TEXT DEFAULT NULL,
                    tablespace TEXT DEFAULT NULL)
```

Append new range partition with `pathman_config.range_interval` as interval.

```
prepend_range_partition(parent_relid REGCLASS,
                    partition_name TEXT DEFAULT NULL,
                    tablespace TEXT DEFAULT NULL)
```

Prepend new range partition with `pathman_config.range_interval` as interval.

```
add_range_partition(parent_relid REGCLASS,
                    start_value ANYELEMENT,
                    end_value ANYELEMENT,
                    partition_name TEXT DEFAULT NULL,
                    tablespace TEXT DEFAULT NULL)
```

Create a new range partition for relation with the specified range bounds. If the `start_value` or the `end_value` is NULL, the corresponding range bound will be infinite.

```
drop_range_partition(partition_relid TEXT, delete_data BOOLEAN DEFAULT TRUE)
```

Drop range partition and all of its data if `delete_data` is true.

```
attach_range_partition(parent_relid REGCLASS,
                    partition_relid REGCLASS,
                    start_value ANYELEMENT,
                    end_value ANYELEMENT)
```

Attach partition to the existing range-partitioned relation. The attached table must have exactly the same structure as the parent table, including the dropped columns. Partition creation callback is invoked if set (see [Section F.34.5.2.2](#)).

```
detach_range_partition(partition_relid REGCLASS)
```

Detach partition from the existing range-partitioned relation.

```
disable_pathman_for(parent_relid REGCLASS)
```

Permanently disable `pg_pathman` partitioning mechanism for the specified parent table and remove the insert trigger if it exists. All partitions and data remain unchanged.

```
drop_partitions(parent_relid REGCLASS,
                delete_data BOOLEAN DEFAULT FALSE)
```

Drop partitions of the parent table (both foreign and local relations). If `delete_data` is false, the data is copied to the parent table first. Default is false.

**F.34.5.3.5. Additional Functions**

```
pathman_version()
```

Returns the `pg_pathman` version number.

```
set_interval(relation REGCLASS, value ANYELEMENT)
```

Update range-partitioned table interval. Note that interval must not be negative and it must not be trivial, i.e. its value should be greater than zero for numeric types, at least 1 microsecond for `timestamp` and at least 1 day for `date`.

```
set_enable_parent(relation REGCLASS, value BOOLEAN)
```

Include/exclude parent table into/from query plan. In original Postgres Pro planner parent table is always included into query plan even if it's empty, which can lead to additional overhead. You can use `disable_parent()` if you are never going to use parent table as a storage. Default value depends on the `partition_data` parameter specified during initial partitioning with the `create_range_partitions()` function. If the `partition_data` parameter was `true`, then all data have already been migrated to partitions and the parent table is disabled. Otherwise, it is enabled.

```
set_auto(relation REGCLASS, value BOOLEAN)
```

Enable/disable auto partition propagation (only for range partitioning). It is enabled by default.

```
set_init_callback(relation REGCLASS, callback REGPROCEDURE DEFAULT 0)
```

Set partition creation callback to be invoked for each attached or created partition (both hash and range). If callback is marked with `SECURITY INVOKER`, it is executed with the privileges of the user who produced a statement that has led to creation of a new partition. For example:

```
INSERT INTO partitioned_table VALUES (-5)
```

The callback must have the following signature: `part_init_callback(args JSONB) RETURNS VOID`. Parameter `arg` consists of several fields whose presence depends on partitioning type:

```
/* Range-partitioned table abc (child abc_4) */
```

```
{
  "parent":    "abc",
  "parttype":  "2",
  "partition": "abc_4",
  "range_max": "401",
  "range_min": "301"
}
```

```
/* Hash-partitioned table abc (child abc_0) */
```

```
{
  "parent":    "abc",
  "parttype":  "1",
  "partition": "abc_0"
}
```

```
set_spawn_using_bgw(relation REGCLASS, value BOOLEAN)
```

When inserting new data beyond the partitioning range, use `SpawnPartitionsWorker` to create new partitions in a separate transaction.

```
create_naming_sequence(parent_relid REGCLASS)
```

Enable automatic partition naming for the specified `relation` table. You must run this function when partitioning this table by composite key.

```
add_to_pathman_config(parent_relid    REGCLASS,
                    expression        TEXT,
                    range_interval    TEXT)
add_to_pathman_config(parent_relid    REGCLASS,
                    expression        TEXT)
```

Register the specified relation table with `pg_pathman` to enable partitioning by the provided expression. For range partitioning, the `range_interval` argument is mandatory. You can set it to `NULL` if you are going to add partition manually.

```
generate_range_bounds(p_start        ANYELEMENT,
                    p_interval    INTERVAL,
                    p_count        INTEGER)
```

```
generate_range_bounds(p_start        ANYELEMENT,
                    p_interval    ANYELEMENT,
                    p_count        INTEGER)
```

Build the `bounds` array that defines the bounds for partitions to be created. You can pass this array as an argument to the `create_range_partitions()` function.

## F.35. `pgpro_pwr`

The `pgpro_pwr` module is designed to discover most resource-intensive activities in your database. (PWR, pronounced like "power", is an abbreviation of Postgres Pro Workload Reporting.) This extension is based on Postgres Pro's [Statistics Collector](#) views and the `pgpro_stats` or `pg_stat_statements` extension.

### Note

Although `pgpro_pwr` can work with the `pg_stat_statements` extension, it is recommended that you use the `pgpro_stats` extension since it provides statement plans, wait events sampling and load distribution statistics for databases, roles, client hosts and applications.

Below, use of `pgpro_stats` is assumed unless otherwise noted.

If you cannot use `pgpro_stats` for an observed database, but the `pg_stat_kcache` extension is available, `pgpro_pwr` can process `pg_stat_kcache` data, which also provides information about CPU resource usage of statements and filesystem load (*rusage*).

`pgpro_pwr` can obtain summary wait statistics from the `pg_wait_sampling` extension. When `pg_wait_sampling` is in use, `pgpro_pwr` will reset the wait sampling profile on every sample.

`pgpro_pwr` is based on cumulative statistics sampling. Each sample contains statistic increments for most active objects and queries since the time when the previous sample was taken, or more concisely, *since the previous sample*. This data is later used to generate reports.

`pgpro_pwr` provides functions to collect samples. Regular sampling allows building a report on the database workload in the past.

`pgpro_pwr` allows you to take explicit samples during batch processing, load testing, etc.

Any time a sample is taken, `pgpro_stats_statements_reset()` (see [pgpro\\_stats](#) for the function description) is called to ensure that statement statistics will not be lost when the statements count

exceed `pgpro_stats.max` (see [Section F.37.7.1](#)). The report will also contain a section informing you of whether the count of captured statements in any sample reaches 90% of `pgpro_stats.max`.

`pgpro_pwr` installed on one Postgres Pro server can also collect statistics from other servers. This feature is useful for gathering workload statistics from hot standbys on the master server. To benefit from it, make sure that all server names and connection strings are specified and that the `pgpro_pwr` server can connect to all databases on all servers.

### F.35.1. `pgpro_pwr` Architecture

The extension consists of the following parts:

- *Historical repository* is a storage for sampling data. The repository is a set of extension tables.

#### Note

Among the rest, `pgpro_pwr` tables store query texts, which can contain sensitive information. So, for security reasons, restrict access to the repository as appropriate.

- *Sample management engine* comprises functions used to [take samples](#) and maintain the repository by removing obsolete sample data.
- *Report engine* comprises functions for [generating reports](#) based on data from the historical repository.
- *Administrative functions* allow you to create and manage [servers](#) and [baselines](#).

### F.35.2. Prerequisites

The prerequisites assume that `pgpro_pwr`, which is usually installed in a *target* cluster, i.e., the cluster that you will mainly track the workload for, the extension can also collect performance data from other clusters.

#### F.35.2.1. For the `pgpro_pwr` Database

The `pgpro_pwr` extension depends on [PL/pgSQL](#) and the [dblink](#) extension.

#### F.35.2.2. For the Target Server

The target server must allow connections to all databases from the server where `pgpro_pwr` is running. To connect to the target server, provide a connection string where a particular database on this server is specified. This database is of high importance for `pgpro_pwr` since the functionality of the [pgpro\\_stats](#) or [pg\\_stat\\_statements](#) extensions will be provided through this database. Note, however, that `pgpro_pwr` will also connect to all the other databases on this server.

Optionally, for completeness of gathered statistics:

- If statement statistics are needed in reports, [pgpro\\_stats](#) must be installed and configured in the aforementioned database. The following settings may affect the completeness and accuracy of gathered statistics:

- `pgpro_stats.max`

Low setting of this parameter may cause some statement statistics to be wiped out before the sample is taken. A report will warn you if the value of `pgpro_stats.max` seems undersized.

- `pgpro_stats.track`

Avoid changing the default value of `'top'` (note that the value of `'all'` will affect the accuracy of `%Total` fields for statements-related sections of a report).

- Set the parameters of the Postgres Pro's [Statistics Collector](#) as follows:

```
track_activities = on
track_counts = on
track_io_timing = on
track_wal_io_timing = on # Since PostgreSQL 14
track_functions = all/pl
```

### F.35.3. Installation and Setup

#### Note

`pgpro_pwr` creates a bunch of database objects, so installation in a dedicated schema is recommended.

Although the use of `pgpro_pwr` with superuser privileges does not have any issues, superuser privileges are not necessary. So you can choose one of the following setup procedures depending on your configuration and security requirements or customize them to meet your needs:

#### F.35.3.1. Simple Setup

Use this setup procedure when `pgpro_pwr` is to be installed on the target cluster to only track its workload as superuser.

Create a schema for the `pgpro_pwr` installation and create the extension:

```
CREATE SCHEMA profile;
CREATE EXTENSION pgpro_pwr SCHEMA profile;
```

#### F.35.3.2. Complex Setup

Use this setup procedure when you intend to use `pgpro_pwr` for tracking workload on one or more servers and need to follow the principle of least privilege.

##### F.35.3.2.1. In the Target Server Database

Create a user for `pgpro_pwr` on the target server:

```
CREATE USER stat_user PASSWORD 'stat_user_pwd';
```

Make sure this user has permissions to connect to any database in the target cluster (by default, it is true) and that `pg_hba.conf` permits such a connection from the `pgpro_pwr` database host. Also, grant `stat_user` with membership in the `pg_read_all_stats` role and the `EXECUTE` privilege on the `pgpro_stats_statements_reset()` function:

```
GRANT pg_read_all_stats TO stat_user;
GRANT EXECUTE ON FUNCTION pgpro_stats_statements_reset TO stat_user;
```

##### F.35.3.2.2. In the `pgpro_pwr` Database

Create an unprivileged user:

```
CREATE USER pwr_user;
```

This user will be the owner of the extension schema and will collect samples.

Create a schema for the `pgpro_pwr` installation:

```
CREATE SCHEMA profile AUTHORIZATION pwr_user;
```

Grant the `USAGE` privilege on the schema where the `dblink` extension resides:

```
GRANT USAGE ON SCHEMA public TO pwr_user;
```

Create the extension using `pwr_user` account:

```
\c - pwr_user
CREATE EXTENSION pgpro_pwr SCHEMA profile;
```

Define the connection parameters of the target server for `pgpro_pwr`. For example:

```
SELECT profile.create_server('target_server_name', 'host=192.168.1.100 dbname=postgres
port=5432');
```

The connection string provided will be used in the `dblink_connect()` call while executing the `take_sample()` function.

### Note

Connection strings are stored in a `pgpro_pwr` table in clear-text form. Make sure no other database users can access tables of the `pgpro_pwr` extension.

#### F.35.3.3. Setting Extension Parameters

In `postgresql.conf`, you can define the following `pgpro_pwr` parameters:

`pgpro_pwr.max` (integer)

Number of top objects (statements, relations, etc.) to be reported in each sorted report table. This parameter affects the size of a sample.

The default value is 20.

`pgpro_pwr.max_sample_age` (integer)

Retention time of the sample, in days. Samples aged `pgpro_pwr.max_sample_age` days and older are automatically deleted on the next `take_sample()` call.

The default value is 7 days.

`pgpro_pwr.max_query_length` (integer)

Maximum query length allowed in reports. All queries in a report will be truncated to `pgpro_pwr.max_query_length` characters.

The default value is 20 000 characters.

`pgpro_pwr.track_sample_timings` (boolean)

Enables collecting detailed timing statistics of `pgpro_pwr`'s own sampling procedures. Set this parameter to diagnose why sampling functions run slowly. Collected timing statistics will be available in the `v_sample_timings` view.

The default value is `off`.

#### F.35.4. Managing Servers

Once installed, `pgpro_pwr` creates one enabled `local` server for the current cluster. If a server is *enabled*, `pgpro_pwr` includes it in sampling when no server is explicitly specified (see `take_sample()` for details). A server that is not enabled is referred to as *disabled*.

The default connection string for a local node contains only `dbname` and `port` parameters. The values of these parameters are taken from the connection used to create the extension. You can change the server connection string using the `set_server_connstr()` function when needed.

### F.35.4.1. Server Management Functions

Use the following `pgpro_pwr` functions for server management:

```
create_server(server name, connstr text, enabled boolean DEFAULT TRUE, max_sample_age
integer DEFAULT NULL description text DEFAULT NULL)
```

Creates a server definition.

Arguments:

- *server* — server name. Must be unique.
- *connstr* — connection string. Must contain all the necessary settings to connect from `pgpro_pwr` server to the target server database.
- *enabled* — set to include the server in sampling by the `take_sample()` function without arguments.
- *max\_sample\_age* — retention time of the sample. Overrides the global `pgpro_pwr.max_sample_age` setting for this server.
- *description* — server description text, to be included in reports.

Here is an example of how to create a server definition:

```
SELECT profile.create_server('omega','host=192.168.1.100 dbname=postgres
port=5432');
```

```
drop_server(server name)
```

Drops a server and all its samples.

```
set_server_description(server name description text)
```

Sets a new server description.

```
enable_server(server name)
```

Includes a server in sampling by the `take_sample()` function without arguments.

```
disable_server(server name)
```

Excludes a server from sampling by the `take_sample()` function without arguments.

```
rename_server(server name, new_name name)
```

Renames a server.

```
set_server_max_sample_age(server name, max_sample_age integer)
```

Sets the retention period for a server (in days). To reset the server retention, set the value of `max_sample_age` to `NULL`.

```
set_server_db_exclude(server name, exclude_db name[])
```

Excludes a list of databases on a server from sampling. Use when `pgpro_pwr` is unable to connect to some databases in a cluster (for example, in Amazon RDS instances).

```
set_server_connstr(server name, server_connstr text)
```

Sets the connection string for a server.

```
show_servers()
```

Displays the list of configured servers.

### F.35.5. Managing Samples

A *sample* contains the database workload statistics since the previous sample

### F.35.5.1. Sampling Functions

The following `pgpro_pwr` functions relate to sampling:

```
take_sample()  
take_sample(server name [, skip_sizes boolean])
```

Takes samples.

If the parameter is omitted, the function takes a sample on each enabled server. Servers are accessed for sampling sequentially, one by one. The function returns a table with the following columns:

- `server` — server name.
- `result` — result of taking the sample. Can be `OK` if the sample was taken successfully or contain the error trace text in case of exception.
- `elapsed` — time elapsed while the sample was taken.

If called with the parameter, the function takes a sample on the specified server even if this server is disabled. Use when you need different sampling frequencies on specific servers. Returns 0 on success.

Arguments:

- `server` — server name.
- `skip_sizes` — if omitted or set to null, the size-collection policy applies; if `false`, relation sizes are collected; if `true`, the collection of relation sizes is skipped.

```
take_sample_subset([sets_cnt integer, current_set integer])
```

Takes a sample on each server in a subset of servers. Use to take samples on servers in parallel if you have many enabled servers. Although PL/pgSQL does not support parallel execution, you can call this function in parallel sessions. This function returns the same type as `take_sample()`. If both parameters are omitted, the function behaves like the `take_sample()` function, i.e., it takes a sample on all enabled servers one by one.

Arguments:

- `sets_cnt` — number of subsets to divide all enabled servers into.
- `current_set` — number of the subset to collect samples for. Takes values from 0 through `sets_cnt - 1`. For the specified subset, samples are collected as usual, server by server.

If a reset of statistics since the previous sample was detected, `pgpro_pwr` treats corresponding absolute values as differentials; however, the accuracy will be affected anyway.

```
show_samples([server name,] [days integer])
```

Returns a table with information on server samples (local server is assumed if `server` is omitted) for the last `days` days (all existing samples are assumed if omitted). This table has the following columns:

- `sample` — sample identifier.
- `sample_time` — time when this sample was taken.
- `dbstats_reset` — `NULL` or the statistics reset timestamp of the `pg_stat_database` view if the statistics were reset since the previous sample.
- `clustats_reset` — `NULL` or the statistics reset timestamp of the `pg_stat_bgwriter` view if the statistics were reset since the previous sample.
- `archstats_reset` — `NULL` or the statistics reset timestamp of the `pg_stat_archiver` view if the statistics were reset since the previous sample.

Sampling functions also maintain the server repository by deleting obsolete samples and baselines according to the retention policy.

### F.35.5.2. Taking Samples

To take samples for all enabled servers, call the `take_sample()` function. Usually, one or two samples per hour is sufficient. You can use a cron-like tool to schedule sampling. Here is an example for a 30-minute sampling period:

```
*/30 * * * * psql -c 'SELECT profile.take_sample()' &> /dev/null
```

However, the results of such a call are not checked for errors. In a production environment, function results can be used for monitoring. This function returns `OK` for all servers with successfully taken samples and shows error text for failed servers:

```
SELECT * FROM take_sample();
 server | result
 | elapsed
-----+-----
ok_node | OK
 | 00:00:00.48
fail_node | could not establish connection
+| 00:00:00
 | SQL statement "SELECT dblink_connect('server_connection',server_connstr)"
+|
 | PL/pgSQL function take_sample(integer) line 69 at PERFORM
+|
 | PL/pgSQL function take_sample_subset(integer,integer) line 27 at
assignment+|
 | SQL function "take_sample" statement 1
+|
 | FATAL: database "postgresno" does not exist
 |
(2 rows)
```

### F.35.5.3. Sample Retention Policy

You can define sample retention at the following levels:

#### 1. *Global*

The value of the `pgpro_pwr.max_sample_age` parameter in the `postgresql.conf` file defines a common retention setting, which is effective if none of other related settings are defined.

#### 2. *Server*

Specifying the `max_sample_age` parameter while creating a server or calling the `set_server_max_sample_age(server,max_sample_age)` function for an existing server defines the retention for the server. A server retention setting overrides `pgpro_pwr.max_sample_age` for a specific server.

#### 3. *Baseline*

A [baseline](#) created overrides all the other retention periods for included samples.

## F.35.6. Managing the Collection of Relation Sizes

It may take considerable time to collect sizes of all relations in a database by Postgres Pro relation-size functions. Besides, those functions require `AccessExclusiveLock` on a relation. However, it may be sufficient for you to collect relation sizes on a daily basis. `pgpro_pwr` allows you to skip collecting relation sizes by defining the *size-collection policy* for servers. The policy defines:

- A daily window when the collection of relation sizes is permitted.

- A minimum gap between two samples with relation sizes collected.

When the size-collection policy is defined, sampling functions collect relation sizes only when the sample is taken in the defined window and the previous sample with sizes is older than the gap. The following function defines this policy:

```
set_server_size_sampling(server name, window_start time with time zone DEFAULT NULL,
window_duration interval hour to second DEFAULT NULL, sample_interval interval day to
minute DEFAULT NULL)
```

Defines the size-collection policy for a server.

Arguments:

- *server* — server name.
- *window\_start* — start time of the size-collection window.
- *window\_duration* — duration of the size-collection window.
- *sample\_interval* — minimum time gap between two samples with relation sizes collected.

### Note

When you build a report between samples either of which lacks relation-size data, relation-growth sections will be based on `pg_class.relpages` data. However, you can expand the report interval bounds to the nearest samples with relation sizes collected using the `with_growth` parameter of [report generation functions](#); this makes the growth data more accurate.

Relation sizes are needed to calculate sequentially scanned volume for tables and explicit vacuum load for indexes.

Example:

```
SELECT set_server_size_sampling('local','23:00+03',interval '2 hour',interval '8
hour');
```

The `show_servers_size_sampling` function shows size collection policies for all servers:

```
postgres=# SELECT * FROM show_servers_size_sampling();
server_name | window_start | window_end | window_duration | sample_interval |
limited_collection
-----+-----+-----+-----+-----+-----
local      | 23:00:00+03 | 01:00:00+03 | 02:00:00        | 08:00:00        | t
```

## F.35.7. Managing Baselines

A *baseline* is a named sequence of samples that has its own retention setting. A baseline can be used as a sample interval in report generation functions. An undefined baseline retention means infinite retention. Use baselines to save information about the database workload for a certain time interval.

### F.35.7.1. Baseline Management Functions

Use the following `pgpro_pwr` functions for baseline management:

```
create_baseline([server name,] baseline varchar(25), start_id integer, end_id integer [,
days integer])
create_baseline([server name,] baseline varchar(25), time_range tstzrange [, days
integer])
```

Creates a baseline.

Arguments:

- *server* — server name. *local* sever is assumed if omitted.
- *baseline* — baseline name. Must be unique for a server.
- *start\_id* — identifier of the first sample in the baseline.
- *end\_id* — identifier of the last sample in the baseline.
- *time\_range* — time interval for the baseline. The baseline will include all samples for the minimal interval that covers *time\_range*.
- *days* — baseline retention time, defined in integer days since `now()`. Omit or set to null for infinite retention.

```
drop_baseline([server name,] baseline varchar(25))
```

Drops a baseline. For the meaning and usage details of function arguments, see [create\\_baseline](#). Dropping a baseline does not mean dropping all its samples immediately. The baseline retention just no longer applies to them.

```
keep_baseline([server name,] baseline varchar(25) [, days integer])
```

Changes the retention of a baseline. For the meaning and usage details of function arguments, see [create\\_baseline](#). Omit the *baseline* parameter or pass null to it to change the retention of all existing baselines.

```
show_baselines([server name])
```

Displays existing baselines. Call `show_baselines` to get information about the baselines, such as names, sampling intervals and retention periods. *local* sever is assumed if the *server* parameter is omitted.

## F.35.8. Data Export and Import

Collected samples can be exported from one instance of the `pgpro_pwr` extension and then loaded into another one. This feature helps you to move server data from one instance to another or to send collected data to your support team.

### F.35.8.1. Data Export

The [export\\_data](#) function exports data to a regular table. You can use any method available to export this table from your database. For example, you can use the `\copy` meta-command of [psql](#) to obtain a single `csv` file:

```
postgres=# \copy (select * from export_data()) to 'export.csv'
```

### F.35.8.2. Data Import

Since data can only be imported from a local table, first, load the data you exported. Using the `\copy` meta-command again:

```
postgres=# CREATE TABLE import (section_id bigint, row_data json);
CREATE TABLE
postgres=# \copy import from 'export.csv'
COPY 6437
```

Now you can import the data by providing the `import` table to the [import\\_data](#) function:

```
postgres=# SELECT * FROM import_data('import');
```

After successful import, you can drop the `import` table.

#### Note

If server data is imported for the first time, your local `pgpro_pwr` servers with matching names will cause a conflict during import. To avoid this, you can temporarily rename such servers or you

can specify the server name prefix for import operations. However, during import of new data for already imported servers, they are matched by system identifiers, so feel free to rename imported servers. Also keep in mind that `pgpro_pwr` sets servers being imported to the *disabled* state for `take_sample()` to bypass them.

### F.35.8.3. Export and Import Functions

Use these functions to export or import data:

```
export_data([server name, [min_sample_id integer,] [max_sample_id integer,]] [,
obfuscate_queries boolean])
```

Exports collected data.

Arguments:

- *server* — server name. All configured servers are assumed if omitted.
- *min\_sample\_id*, *max\_sample\_id* — sample identifiers to bound the export (inclusive). If *min\_sample\_id* is omitted or set to null, all samples until *max\_sample\_id* sample are exported; if *max\_sample\_id* is omitted or set to null, all samples since *min\_sample\_id* sample are exported.
- *obfuscate\_queries* — if true, query texts are exported as MD5 hash.

```
import_data(data regclass [, server_name_prefix text])
```

Imports previously exported data. Returns the number of actually loaded rows in `pgpro_pwr` tables.

Arguments:

- *data* is the name of the table containing import data.
- *server\_name\_prefix* specifies the server name prefix for the import operation. It can be used to avoid name conflicts.

## F.35.9. Report Generation Functions

`pgpro_pwr` reports are generated in HTML format by reporting functions. The following types of reports are available:

- *Regular reports* provide statistics on the workload for an interval.
- *Differential reports* provide statistics on the same objects for two intervals. Corresponding values are located next to each other, which makes it easy to compare the workloads.

Reporting functions take sample identifiers, baselines or time ranges to determine the intervals. For time ranges, these are the minimal intervals that cover the ranges.

### F.35.9.1. Regular Reports

Use this function to generate regular reports:

```
get_report([server name,] start_id integer, end_id integer [, description text [,
with_growth boolean]])
get_report([server name,] time_range tstzrange [, description text [, with_growth
boolean]])
get_report([server name,] baseline varchar(25) [, description text [, with_growth
boolean]])
```

Generates a regular report.

Arguments:

- *server* — server name. `local` sever is assumed if omitted.
- *start\_id* — identifier of the interval starting sample.
- *end\_id* — identifier of the interval ending sample.
- *baseline* — baseline name.
- *time\_range* — time range.
- *description* — short text to be included in the report as its description.
- *with\_growth* — flag requesting interval expansion to the nearest bounds with data on relation growth available. The default value is `false`.

### F.35.9.2. Differential Reports

Use this function to generate differential reports:

```
get_diffreport([server name,] start1_id integer, end1_id integer, start2_id integer,
end2_id integer [, description text [, with_growth boolean]])
get_diffreport([server name,] time_range1 tstzrange, time_range2 tstzrange [, description
text [, with_growth boolean]])
get_diffreport([server name,] baseline1 varchar(25), baseline2 varchar(25) [, description
text [, with_growth boolean]])
get_diffreport([server name,] baseline1 varchar(25), time_range2 tstzrange [, description
text [, with_growth boolean]])
get_diffreport([server name,] time_range1 tstzrange, baseline2 varchar(25) [, description
text [, with_growth boolean]])
get_diffreport([server name,] start1_id integer, end1_id integer, baseline2 varchar(25)
[, description text [, with_growth boolean]])
get_diffreport([server name,] baseline1 varchar(25), start2_id integer, end2_id integer
[, description text [, with_growth boolean]])
```

Generates a differential report for two intervals. The combinations of arguments provide possible ways to specify the two intervals.

Arguments:

- *server* — server name. `local` sever is assumed if omitted.
- *start1\_id, end1\_id* — identifiers of the starting and ending samples for the first interval.
- *start2\_id, end2\_id* — identifiers of the starting and ending samples for the second interval.
- *baseline1* — baseline name for the first interval.
- *baseline2* — baseline name for the second interval.
- *time\_range1* — time range for the first interval.
- *time\_range2* — time range for the second interval.
- *description* — short text to be included in the report as its description.
- *with\_growth* — flag requesting interval expansion to the nearest bounds with data on relation growth available. The default value is `false`.

### F.35.9.3. Report Generation Example

Generate a report for the `local` server and interval defined by samples:

```
psql -Aqtc "SELECT profile.get_report(480,482)" -o report_480_482.html
```

For any other server, provide its name:

```
psql -Aqtc "SELECT profile.get_report('omega',12,14)" -o report_omega_12_14.html
```

Generate a report using time ranges:

```
psql -Aqtc "SELECT profile.get_report (tstzrange ('2020-05-13 11:51:35+03', '2020-05-13
11:52:18+03'))" -o report_range.html
```

Generate a relative time-range report:

```
psql -Aqtc "SELECT profile.get_report (tstzrange (now() - interval '1 day', now()))" -o
report_last_day.html
```

## F.35.10. pgpro\_pwr Report Sections

Each pgpro\_pwr report is divided into sections, described below. The number of top objects reported in each sorted report table is specified by the pgpro\_pwr.max parameter.

### F.35.10.1. Server statistics

Tables in this section of a pgpro\_pwr report are described below.

The report table “Database statistics” provides per-database statistics for the report interval. The statistics are based on the `pg_stat_database` view. [Table F.21](#) lists columns of this report table.

**Table F.21. Database statistics**

Column	Description	Field/Calculation
Database	Database name	datname
Commits	Number of committed transactions	xact_commit
Rollbacks	Number of rolled back transactions	xact_rollback
Deadlocks	Number of deadlocks detected	deadlocks
Checksum Failures	Number of data page checksum failures detected in this database. This field is only shown if any checksum failures were detected in this database during the report interval.	checksum_failures
Checksums Last	Time at which the last data page checksum failure was detected in this database. This field is only shown if any checksum failures were detected in this database during the report interval.	checksum_last_failure
Hit%	Buffer cache hit ratio, i.e., percentage of pages fetched from buffers in all pages fetched	
Read	Number of disk blocks read in this database	blks_read
Hit	Number of times disk blocks were found already in the buffer cache	blks_hit
Ret	Number of returned tuples	tup_returned
Fet	Number of fetched tuples	tup_fetched
Ins	Number of inserted tuples	tup_inserted
Upd	Number of updated tuples	tup_updated

Column	Description	Field/Calculation
Del	Number of deleted tuples	tup_deleted
Temp Size	Total amount of data written to temporary files by queries in this database	temp_bytes
Temp Files	Number of temporary files created by queries in this database	temp_files
Size	Database size at the time of the last sample in the report interval	pg_database_size()
Growth	Database growth during the report interval	pg_database_size() increment between interval bounds

Table “Session statistics by database” is available in the report for Postgres Pro databases starting with version 14. This table is based on the `pg_stat_database` view of the [Statistics Collector](#). [Table F.22](#) lists columns of this report table. Times are provided in seconds.

**Table F.22. Session statistics by database**

Column	Description	Field/Calculation
Database	Database name	
Timing Total	Time spent by database sessions in this database during the report interval (note that statistics are only updated when the state of a session changes, so if sessions have been idle for a long time, this idle time won't be included)	session_time
Timing Active	Time spent executing SQL statements in this database during the report interval (this corresponds to the states <code>active</code> and <code>fastpath</code> function call in <code>pg_stat_activity</code> )	active_time
Timing Idle(T)	Time spent idling while in a transaction in this database during the report interval (this corresponds to the states <code>idle in transaction</code> and <code>idle in transaction (aborted)</code> in <code>pg_stat_activity</code> )	idle_in_transaction_time
Sessions Established	Total number of sessions established to this database during the report interval	sessions
Sessions Abandoned	Number of database sessions to this database that were terminated because connection to the client was lost during the report interval	sessions_abandoned
Sessions Fatal	Number of database sessions to this database that were	sessions_fatal

Column	Description	Field/Calculation
	terminated by fatal errors during the report interval	
Sessions Killed	Number of database sessions to this database that were terminated by operator intervention during the report interval	sessions_killed

In Postgres Pro databases of versions that include [pgpro\\_stats](#) version starting with 1.4, workload statistics of vacuum processes are available. The "Database vacuum statistics" table of the report provides per-database aggregated total vacuum statistics based on the `pgpro_stats_vacuum_tables` view. [Table F.23](#) lists columns of this report table. Times are provided in seconds.

**Table F.23. Database vacuum statistics**

Column	Description	Field/Calculation
Database	Database name	
Blocks fetched	Total number of database blocks fetched by vacuum operations	<code>total_blks_read + total_blks_hit</code>
%Total	Total number of database blocks fetched (read+hit) by vacuum operations as the percentage of all blocks fetched in the cluster	<code>Blocks fetched * 100 / Cluster fetched</code>
Blocks read	Total number of database blocks read by vacuum operations	<code>total_blks_read</code>
%Total	Total number of database blocks read by vacuum operations as the percentage of all blocks read in the cluster	<code>Blocks read * 100 / Cluster read</code>
VM Frozen	Total number of blocks marked all-frozen in the visibility map	<code>pages_frozen</code>
VM Visible	Total number of blocks marked all-visible in the visibility map	<code>pages_all_visible</code>
Tuples deleted	Total number of dead tuples vacuum operations deleted from tables of this database	<code>tuples_deleted</code>
Tuples left	Total number of dead tuples vacuum operations left in tables of this database due to their visibility in transactions	<code>dead_tuples</code>
%Eff	Vacuum efficiency in terms of deleted tuples. This is the percentage of tuples deleted from tables of this database in all dead tuples to be deleted from tables of this database.	<code>tuples_deleted * 100 / ( tuples_deleted + dead_tuples )</code>
WAL size	Total amount of WAL bytes generated by vacuum operations performed on tables of this database	<code>wal_bytes</code>
Read I/O time	Time spent reading database blocks by vacuum operations	<code>blk_read_time</code>

Column	Description	Field/Calculation
	performed on tables of this database	
Write I/O time	Time spent writing database blocks by vacuum operations performed on tables of this database	blk_write_time
%Total	Vacuum I/O time spent as the percentage of whole cluster I/O time	
Total vacuum time	Total time of vacuuming tables of this database	total_time
Delay vacuum time	Time spent sleeping in a vacuum delay point by vacuum operations performed on tables of this database	delay_time
User CPU time	User CPU time of vacuuming tables of this database	user_time
System CPU time	System CPU time of vacuuming tables of this database	system_time
Interrupts	Number of times vacuum operations performed on tables of this database were interrupted on any errors	interrupts

If the [pgpro\\_stats](#) extension supporting invalidation statistics was available during the report interval, the "Invalidation messages by database" table of the report provides per-database aggregated total invalidation message statistics. [Table F.24](#) lists columns of this report table. Times are provided in seconds.

**Table F.24. Invalidation messages by database**

Column	Description	Field/Calculation
Database	Database name	
Invalidation messages sent	Total number of invalidation messages sent by backends in this database. Statistics are provided for corresponding message types of <code>pgpro_stats_inval_msgs</code>	Fields of <code>pgpro_stats_totals.inval_msgs</code>
Cache resets	Total number of shared cache resets	<code>pgpro_stats_totals.cache_resets</code>

If the [pgpro\\_stats](#) extension was available during the report interval, the "Statement statistics by database" table of the report provides per-database aggregated total statistics for the `pgpro_stats_statements` view data. [Table F.25](#) lists columns of this report table. Times are provided in seconds.

**Table F.25. Statement statistics by database**

Column	Description	Field/Calculation
Database	Database name	
Calls	Number of times all statements in the database were executed	calls

Column	Description	Field/Calculation
Plan Time	Time spent planning all statements in the database	Sum of <code>total_plan_time</code>
Exec Time	Time spent executing all statements in the database	Sum of <code>total_exec_time</code>
Read Time	Time spent reading blocks by all statements in the database	Sum of <code>blk_read_time</code>
Write Time	Time spent writing blocks by all statements in the database	Sum of <code>blk_write_time</code>
Trg Time	Time spent executing trigger functions by all statements in the database	
Shared Fetched	Total number of shared blocks fetched by all statements in the database	Sum of ( <code>shared_blks_read</code> + <code>shared_blks_hit</code> )
Local Fetched	Total number of local blocks fetched by all statements in the database	Sum of ( <code>local_blks_read</code> + <code>local_blks_hit</code> )
Shared Dirtied	Total number of shared blocks dirtied by all statements in the database	Sum of <code>shared_blks_dirtied</code>
Local Dirtied	Total number of local blocks dirtied by all statements in the database	Sum of <code>local_blks_dirtied</code>
Read Temp	Total number of temp blocks read by all statements in the database	Sum of <code>temp_blks_read</code>
Write Temp	Total number of temp blocks written by all statements in the database	Sum of <code>temp_blks_written</code>
Read Local	Total number of local blocks read by all statements in the database	Sum of <code>local_blks_read</code>
Write Local	Total number of local blocks written by all statements in the database	Sum of <code>local_blks_written</code>
Statements	Total number of captured statements	
WAL Size	Total amount of WAL generated by all statements in the database	Sum of <code>wal_bytes</code>

The report table “Cluster statistics” provides data from the `pg_stat_bgwriter` view. Table F.26 lists rows of this report table. Times are provided in seconds.

**Table F.26. Cluster statistics**

Row	Description	Field/Calculation
Scheduled checkpoints	Number of scheduled checkpoints that have been performed	<code>checkpoints_timed</code>
Requested checkpoints	Number of requested checkpoints that have been performed	<code>checkpoints_req</code>

Row	Description	Field/Calculation
Checkpoint write time (s)	Total amount of time that has been spent in the portion of checkpoint processing where files are written to disk	checkpoint_write_time
Checkpoint sync time (s)	Total amount of time that has been spent in the portion of checkpoint processing where files are synchronized to disk	checkpoint_sync_time
Checkpoint buffers written	Number of buffers written during checkpoints	buffers_checkpoint
Background buffers written	Number of buffers written by the background writer	buffers_clean
Backend buffers written	Number of buffers written directly by a backend	buffers_backend
Backend fsync count	Number of times a backend had to execute its own fsync call (normally the background writer handles those even when the backend does its own write)	buffers_backend_fsync
Bgwriter interrupts (too many buffers)	Number of times the background writer stopped a cleaning scan because it had written too many buffers	maxwritten_clean
Number of buffers allocated	Total number of buffers allocated	buffers_alloc
WAL generated	Total amount of WAL generated	pg_current_wal_lsn() value increment
WAL segments archived	Total number of archived WAL segments	Based on <code>pg_stat_archiver.archived_count</code>
WAL segments archive failed	Total number of WAL segment archiver failures	Based on <code>pg_stat_archiver.failed_count</code>

Table “WAL statistics” is available in the report for Postgres Pro databases starting with version 14. This table is based on the `pg_stat_wal` view of the [Statistics Collector](#). [Table F.27](#) lists columns of this report table. Times are provided in seconds.

**Table F.27. WAL statistics**

Row	Description	Field/Calculation
WAL generated	Total amount of WAL generated during the report interval	wal_bytes
WAL per second	Average amount of WAL generated per second during the report interval	wal_bytes / report_duration
WAL records	Total number of WAL records generated during the report interval	wal_records
WAL FPI	Total number of WAL full page images generated during the report interval	wal_fpi
WAL buffers full	Number of times WAL data was written to disk because WAL	wal_buffers_full

Row	Description	Field/Calculation
	buffers became full during the report interval	
WAL writes	Number of times WAL buffers were written out to disk via <code>XLogWrite</code> request during the report interval	<code>wal_write</code>
WAL writes per second	Average number of times WAL buffers were written out to disk via <code>XLogWrite</code> request per second during the report interval	<code>wal_write / report_duration</code>
WAL sync	Number of times WAL files were synced to disk via <code>issue_xlog_fsync</code> request during the report interval (if <code>fsync</code> is on and <code>wal_sync_method</code> is either <code>fdatasync</code> , <code>fsync</code> or <code>fsync_writethrough</code> , otherwise zero). See <a href="#">Section 28.4</a> for more information about the internal WAL function <code>issue_xlog_fsync</code> .	<code>wal_sync</code>
WAL syncs per second	Average number of times WAL files were synced to disk via <code>issue_xlog_fsync</code> request per second during the report interval	<code>wal_sync / report_duration</code>
WAL write time	Total amount of time spent writing WAL buffers to disk via <code>XLogWrite</code> request during the report interval (if <code>track_wal_io_timing</code> is enabled, otherwise zero; for more details, see <a href="#">Section 18.9</a> ). This includes the sync time when <code>wal_sync_method</code> is either <code>open_datasync</code> or <code>open_sync</code> .	<code>wal_write_time</code>
WAL write duty	WAL write time as the percentage of the report interval duration	<code>wal_write_time * 100 / report_duration</code>
WAL sync time	Total amount of time spent syncing WAL files to disk via <code>issue_xlog_fsync</code> request during the report interval (if <code>track_wal_io_timing</code> is enabled, <code>fsync</code> is on, and <code>wal_sync_method</code> is either <code>fdatasync</code> , <code>fsync</code> or <code>fsync_writethrough</code> , otherwise zero).	<code>wal_sync_time</code>
WAL sync duty	WAL sync time as the percentage of the report interval duration	<code>wal_sync_time * 100 / report_duration</code>

The report table “Tablespace statistics” provides information on the sizes and growth of tablespaces. [Table F.28](#) lists columns of this report table.

**Table F.28. Tablespace statistics**

Column	Description	Field/Calculation
Tablespace	Tablespace name	<code>pg_tablespace .spcname</code>
Path	Tablespace path	<code>pg_tablespace_location()</code>
Size	Tablespace size at the time of the last sample in the report interval	<code>pg_tablespace_size()</code>
Growth	Tablespace growth during the report interval	<code>pg_tablespace_size()</code> increment between interval bounds

If the `pgpro_stats` extension was available during the report interval, the report table “Wait statistics by database” shows the total wait time by wait event type and database. [Table F.29](#) lists columns of this report table.

**Table F.29. Wait statistics by database**

Column	Description
Database	Database name
Wait event type	Type of event for which the backends were waiting. Asterisk means aggregation of all wait event types in the database.
Waited (s)	Time spent waiting in events of <code>Wait event type</code> , in seconds
%Total	Percentage of wait time spent in the database events of <code>Wait event type</code> in all wait time for the cluster

If the `pgpro_stats` extension was available during the report interval, the report table “Top wait events” shows top wait events in the cluster by wait time. [Table F.30](#) lists columns of this report table.

**Table F.30. Top wait events**

Column	Description
Database	Database name
Wait event type	The type of event for which the backends were waiting
Wait event	Wait event name for which the backends were waiting
Waited	Total wait time spent in <code>Wait event</code> of the database, in seconds
%Total	Percentage of wait time spent in <code>Wait event</code> of the database in all wait time in the cluster

### F.35.10.2. Load distribution

This section of a `pgpro_pwr` report is based on the `pgpro_stats_totals` view of the `pgpro_stats` extension if it was available during the report interval. Each table in this section provides data for the report interval on load distribution for a certain kind of objects for which aggregated statistics are collected, such as databases, applications, hosts, or users. Each table contains one row for each resource (for example, total time or shared blocks written), where load distribution is shown in graphics, as a stacked bar chart for top objects by load of this resource. If the bar chart area that corresponds to an object is too narrow to include captions, point that area to get a hint with the caption, value and percentage. The report tables “Load distribution among heavily loaded databases”, “Load

distribution among heavily loaded applications”, “Load distribution among heavily loaded hosts” and “Load distribution among heavily loaded users” show load distribution for respective objects. [Table F.31](#) lists rows of these report tables.

**Table F.31. Load distribution**

Row	Description	Calculation
Total time (sec.)	Total time spent in the planning and execution of statements	<code>total_plan_time + total_exec_time</code>
Executed count	Number of queries executed	<code>queries_executed</code>
I/O time (sec.)	Total time the statements spent reading or writing blocks ( if <a href="#">track_io_timing</a> is enabled, otherwise zero)	<code>blk_read_time + blk_write_time</code>
Blocks fetched	Total number of shared block cache hits and shared blocks read by the statements	<code>shared_blks_hit + shared_blks_read</code>
Shared blocks read	Total number of shared blocks read by the statements	<code>shared_blks_read</code>
Shared blocks dirtied	Total number of shared blocks dirtied by the statements	<code>shared_blks_dirtied</code>
Shared blocks written	Total number of shared blocks written by the statements	<code>shared_blks_written</code>
WAL generated	Total amount of WAL generated by the statements	<code>wal_bytes</code>
Temp and Local blocks written	Total number of temporary and local blocks written by the statements	<code>temp_blks_written + local_blks_written</code>
Temp and Local blocks read	Total number of temp and local blocks read by the statements	<code>temp_blks_read + local_blks_read</code>
Invalidation messages sent	Total number of all invalidation messages sent by backends in this database	<code>(pgpro_stats_totals .invalid_msgs ).all</code>
Cache resets	Total number of shared cache resets	<code>pgpro_stats_totals .cache_resets</code>

### F.35.10.3. SQL query statistics

This section of a `pgpro_pwr` report provides data for the report interval on top statements by several important statistics. The data is mainly captured from views of the one of [pgpro\\_stats](#) and [pg\\_stat\\_statements](#) extensions that was available during the report interval, with the precedence of `pgpro_stats`. Tables of this section of the report are described below.

The report table “Top SQL by elapsed time” shows top statements by the sum of `total_plan_time` and `total_exec_time` fields of the `pgpro_stats_statements` or `pg_stat_statements` view. [Table F.32](#) lists columns of this report table. Times are provided in seconds.

**Table F.32. Top SQL by elapsed time**

Column	Description	Field/Calculation
Query ID	Query identifier, as a hash of database ID, user ID and query text. Hex representation of <code>queryid</code> is in square brackets.	

Column	Description	Field/Calculation
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
%Total	Percentage of elapsed time of this statement plan in the total elapsed time of all statements in the cluster	
Elapsed Time (s)	Total time spent in planning and execution of the statement plan	total_plan_time + total_exec_time
Plan Time (s)	Total time spent in planning of the statement	total_plan_time
Exec Time (s)	Total time spent in execution of the statement plan	total_exec_time
Read I/O time (s)	Total time the statement spent reading blocks	blk_read_time
Write I/O time (s)	Total time the statement spent writing blocks	blk_write_time
Usr CPU time (s)	Time spent on CPU in the user space, in seconds	rusage.user_time
Sys CPU time (s)	Time spent on CPU in the system space, in seconds	rusage.system_time
Plans	Number of times the statement was planned	plans
Executions	Number of executions of the statement plan	calls

The report table “Top SQL by planning time” shows top statements by the value of the `total_plan_time` field of the `pgpro_stats_statements` or `pg_stat_statements` view. [Table F.33](#) lists columns of this report table.

**Table F.33. Top SQL by planning time**

Column	Description	Field/Calculation
Query ID	Query identifier, as a hash of database ID, user ID and query text. Hex representation of queryid is in square brackets.	
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
Plan elapsed(s)	Total time spent in planning of the statement, in seconds	total_plan_time
%Elapsed	Percentage of total_plan_time in the sum of total_plan_time and total_exec_time of this statement plan	
Mean plan time	Mean time spent planning the statement, in milliseconds	mean_plan_time

Column	Description	Field/Calculation
Min plan time	Minimum time spent planning the statement, in milliseconds	min_plan_time
Max plan time	Maximum time spent planning the statement, in milliseconds	max_plan_time
StdErr plan time	Population standard deviation of time spent planning the statement, in milliseconds	stddev_plan_time
Plans	Number of times the statement was planned	plans
Executions	Number of executions of the statement plan	calls

The report table “Top SQL by execution time” shows top statements by the value of the `total_time` field of the `pgpro_stats_statements` or `pg_stat_statements` view. [Table F.34](#) lists columns of this report table.

**Table F.34. Top SQL by execution time**

Column	Description	Field/Calculation
Query ID	Query identifier, as a hash of database ID, user ID and query text. Hex representation of <code>queryid</code> is in square brackets.	
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from <code>dbid</code>
Exec (s)	Total time spent executing the statement plan, in seconds	total_exec_time
%Elapsed	Percentage of <code>total_exec_time</code> of this statement plan in this statement elapsed time	
%Total	Percentage of <code>total_exec_time</code> of this statement plan in the total elapsed time of all statements in the cluster	
Read I/O time (s)	Total time spent in reading pages while executing the statement plan, in seconds	blk_read_time
Write I/O time (s)	Total time spent in writing pages while executing the statement plan, in seconds	blk_write_time
Usr CPU time (s)	Time spent on CPU in the user space, in seconds	rusage.user_time
Sys CPU time (s)	Time spent on CPU in the system space, in seconds	rusage.system_time
Rows	Number of rows retrieved or affected by execution of the statement plan	rows
Mean execution time	Mean time spent executing the statement plan, in milliseconds	mean_exec_time

Column	Description	Field/Calculation
Min execution time	Minimum time spent executing the statement plan, in milliseconds	min_exec_time
Max execution time	Maximum time spent executing the statement plan, in milliseconds	max_exec_time
StdErr execution time	Population standard deviation of time spent executing the statement plan, in milliseconds	stddev_exec_time
Executions	Number of executions of this statement plan	calls

The report table “Top SQL by executions” shows top statements by the value of the `calls` field of the `pgpro_stats_statements` or `pg_stat_statements` view. [Table F.35](#) lists columns of this report table.

**Table F.35. Top SQL by executions**

Column	Description	Field/Calculation
Query ID	Query identifier, as a hash of database ID, user ID and query text. Hex representation of <code>queryid</code> is in square brackets.	
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from <code>dbid</code>
Executions	Number of executions of the statement plan	calls
%Total	Percentage of <code>calls</code> of this statement plan in the total <code>calls</code> of all statements in the cluster	
Rows	Number of rows retrieved or affected by execution of the statement plan	rows
Mean (ms)	Mean time spent executing the statement plan, in milliseconds	mean_exec_time
Min (ms)	Minimum time spent executing the statement plan, in milliseconds	min_exec_time
Max (ms)	Maximum time spent executing the statement plan, in milliseconds	max_exec_time
StdErr (ms)	Population standard deviation of time spent executing the statement plan, in milliseconds	stddev_time
Elapsed(s)	Total time spent executing the statement plan, in seconds	total_exec_time

The report table “Top SQL by I/O wait time” shows top statements by read and write time, i.e., sum of values of `blk_read_time` and `blk_write_time` fields of the `pgpro_stats_statements` or `pg_stat_statements` view. [Table F.36](#) lists columns of this report table. Times are provided in seconds.

**Table F.36. Top SQL by I/O wait time**

Column	Description	Field/Calculation
Query ID	Query identifier, as a hash of database ID, user ID and query text. Hex representation of <code>queryid</code> is in square brackets.	
Plan ID	Internal hash code, computed from the tree of the statement plan	<code>planid</code>
Database	Database name for the statement	Derived from <code>dbid</code>
IO(s)	Total time spent in reading and writing while executing this statement plan, i.e., I/O time	<code>blk_read_time + blk_write_time</code>
R(s)	Total time spent in reading while executing this statement plan	<code>blk_read_time</code>
W(s)	Total time spent in writing while executing this statement plan	<code>blk_write_time</code>
%Total	Percentage of I/O time of this statement plan in the total I/O time of all statements in the cluster	
Shr Reads	Total number of shared blocks read while executing the statement plan	<code>shared_blks_read</code>
Loc Reads	Total number of local blocks read while executing the statement plan	<code>local_blks_read</code>
Tmp Reads	Total number of temp blocks read while executing the statement plan	<code>temp_blks_read</code>
Shr Writes	Total number of shared blocks written while executing the statement plan	<code>shared_blks_written</code>
Loc Writes	Total number of local blocks written while executing the statement plan	<code>local_blks_written</code>
Tmp Writes	Total number of temp blocks written while executing the statement plan	<code>temp_blks_written</code>
Elapsed(s)	Total time spent in execution of the statement plan	<code>total_plan_time + total_exec_time</code>
Executions	Number of executions of the statement plan	<code>calls</code>

The report table “Top SQL by shared blocks fetched” shows top statements by the number of read and hit blocks, which helps to detect the most data-intensive statements. [Table F.37](#) lists columns of this report table.

**Table F.37. Top SQL by shared blocks fetched**

Column	Description	Field/Calculation
Query ID	Query identifier, as a hash of database ID, user ID and query text. Hex representation of queryid is in square brackets.	
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
Blks fetched	Number of blocks retrieved while executing the statement plan	shared_blks_hit + shared_blks_read
%Total	Percentage of blocks fetched while executing the statement plan in all blocks fetched for all statements in the cluster	
Hits(%)	Percentage of blocks got from buffers in all blocks got	
Elapsed(s)	Total time spent in execution of the statement plan, in seconds	total_plan_time + total_exec_time
Rows	Number of rows retrieved or affected by execution of the statement plan	rows
Executions	Number of executions of the statement plan	calls

The report table “Top SQL by shared blocks read” shows top statements by the number of shared reads, which helps to detect the most read-intensive statements. [Table F.38](#) lists columns of this report table.

**Table F.38. Top SQL by shared blocks read**

Column	Description	Field/Calculation
Query ID	Query identifier, as a hash of database ID, user ID and query text. Hex representation of queryid is in square brackets.	
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
Reads	Number of shared blocks read while executing this statement plan	shared_blks_read
%Total	Percentage of shared reads for this statement plan in all shared reads of all statements in the cluster	
Hits(%)	Percentage of blocks got from buffers in all blocks got while executing this statement plan	

Column	Description	Field/Calculation
Elapsed (s)	Total time spent in execution of the statement plan, in seconds	total_plan_time + total_exec_time
Rows	Number of rows retrieved or affected by execution of the statement plan	rows
Executions	Number of executions of the statement plan	calls

The report table “Top SQL by shared blocks dirtied” shows top statements by the number of shared dirtied buffers, which helps to detect statements that do most data changes in the cluster. [Table F.39](#) lists columns of this report table.

**Table F.39. Top SQL by shared blocks dirtied**

Column	Description	Field/Calculation
Query ID	Query identifier, as a hash of database ID, user ID and query text. Hex representation of queryid is in square brackets.	
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
Dirtied	Number of shared buffers dirtied while executing this statement plan	shared_blks_dirtied
%Total	Percentage of dirtied shared buffers for this statement plan in all dirtied shared buffers of all statements in the cluster	
Hits (%)	Percentage of blocks got from buffers in all blocks got while executing this statement plan	
WAL	Total amount of WAL bytes generated by the statement plan	wal_bytes
%Total	Percentage of WAL bytes generated by the statement plan in total WAL generated in the cluster	
Elapsed (s)	Total time spent in execution of the statement plan, in seconds	total_plan_time + total_exec_time
Rows	Number of rows retrieved or affected by execution of the statement plan	rows
Executions	Number of executions of the statement plan	calls

The report table “Top SQL by shared blocks written” shows top statements by the number of blocks written. [Table F.40](#) lists columns of this report table.

**Table F.40. Top SQL by shared blocks written**

Column	Description	Field/Calculation
Query ID	Query identifier, as a hash of database ID, user ID and query text. Hex representation of queryid is in square brackets.	
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
Written	Number of blocks written while executing this statement plan	shared_blks_written
%Total	Percentage of blocks written by this statement plan in all written blocks in the cluster	Percentage of shared_blks_written in (pg_stat_bgwriter .buffers_checkpoint + pg_stat_bgwriter .buffers_clean + pg_stat_bgwriter .buffers_backend )
%BackendW	Percentage of blocks written by this statement plan in all blocks in the cluster written by backends	Percentage of shared_blks_written in pg_stat_bgwriter .buffers_backend
Hits (%)	Percentage of blocks got from buffers in all blocks got while executing this statement plan	
Elapsed(s)	Total time spent in execution of the statement plan, in seconds	total_plan_time + total_exec_time
Rows	Number of rows retrieved or affected by execution of the statement plan	rows
Executions	Number of executions of the statement plan	calls

The report table “Top SQL by WAL size” shows top statements by the amount of WAL generated. [Table F.41](#) lists columns of this report table.

**Table F.41. Top SQL by WAL size**

Column	Description	Field/Calculation
Query ID	Query identifier, as a hash of database ID, user ID and query text. Hex representation of queryid is in square brackets.	
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
WAL	Total amount of WAL bytes generated by the statement plan	wal_bytes
%Total	Percentage of WAL bytes generated by the statement plan	

Column	Description	Field/Calculation
	in total WAL generated in the cluster	
Dirtied	Number of shared buffers dirtied while executing this statement plan	shared_blks_dirtied
WAL FPI	Total number of WAL full page images generated by the statement plan	wal_fpi
WAL records	Total number of WAL records generated by the statement plan	wal_records

The report table “Top SQL by temp usage” shows top statements by temporary I/O, which is calculated as the sum of `temp_blks_read`, `temp_blks_written`, `local_blks_read` and `local_blks_written` fields. [Table F.42](#) lists columns of this report table.

**Table F.42. Top SQL by temp usage**

Column	Description	Field/Calculation
Query ID	Query identifier, as a hash of database ID, user ID and query text. Hex representation of queryid is in square brackets.	
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
Local fetched	Number of local blocks retrieved	<code>local_blks_hit + local_blks_read</code>
Hits(%)	Percentage of local blocks got from buffers in all local blocks got	
Write Local (blk)	Number of blocks written by this statement plan that are used in temporary tables	local_blks_written
Write Local %Total	Percentage of <code>local_blks_written</code> of this statement plan in the total of <code>local_blks_written</code> for all statements in the cluster	
Read Local (blk)	Number of blocks read by this statement plan that are used in temporary tables	local_blks_read
Read Local %Total	Percentage of <code>local_blks_read</code> of this statement plan in the total of <code>local_blks_read</code> for all statements in the cluster	
Write Temp (blk)	Number of temp blocks written by this statement plan	temp_blks_written
Write Temp %Total	Percentage of <code>temp_blks_written</code> of this statement plan in the total of <code>temp_blks_</code>	

Column	Description	Field/Calculation
	written for all statements in the cluster	
Read Temp (blk)	Number of temp blocks read by this statement plan	temp_blks_read
Read Temp %Total	Percentage of temp_blks_read of this statement plan in the total of temp_blks_read for all statements in the cluster	
Elapsed(s)	Total time spent in execution of the statement plan, in seconds	total_plan_time + total_exec_time
Rows	Number of rows retrieved or affected by execution of the statement plan	rows
Executions	Number of executions of the statement plan	calls

The report table “Top SQL by invalidation messages sent” shows top statements by the number of invalidation messages sent. [Table F.43](#) lists columns of this report table.

**Table F.43. Top SQL by invalidation messages sent**

Column	Description	Field/Calculation
Query ID	Query identifier, as a hash of database ID, user ID and query text. Hex representation of queryid is in square brackets.	queryid
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
Invalidation messages sent	Total number of invalidation messages sent by backends executing this statement. Statistics are provided for corresponding message types of pgpro_stats_inval_msgs	fields of pgpro_stats_statements .inval_msgs

### F.35.10.3.1. rusage statistics

This section is included in the report only if the [pgpro\\_stats](#) or [pg\\_stat\\_kcache](#) extension was available during the report interval.

The report table “Top SQL by system and user time” shows top statements by the sum of `user_time` and `system_time` fields of [pg\\_stat\\_kcache](#) or of the [pgpro\\_stats\\_totals](#) view. [Table F.44](#) lists columns of this report table.

**Table F.44. Top SQL by system and user time**

Column	Description	Field/Calculation
Query ID	Query identifier, as a hash of database ID, user ID and query text. Hex representation of queryid is in square brackets.	

Column	Description	Field/Calculation
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
Plan User (s)	User CPU time elapsed during planning, in seconds	plan_user_time
Exec User (s)	User CPU time elapsed during execution, in seconds	exec_user_time
User %Total	Percentage of <code>plan_user_time</code> + <code>exec_user_time</code> in the total user CPU time for all statements	
Plan System (s)	System CPU time elapsed during planning, in seconds	plan_system_time
Exec System (s)	System CPU time elapsed during execution, in seconds	exec_system_time
System %Total	Percentage of <code>plan_system_time</code> + <code>exec_system_time</code> in the total system CPU time for all statements	

The report table “Top SQL by reads/writes done by filesystem layer” shows top statements by the sum of reads and writes fields of `pg_stat_kcache`. [Table F.45](#) lists columns of this report table.

**Table F.45. Top SQL by reads/writes done by filesystem layer**

Column	Description	Field/Calculation
Query ID	Query identifier, as a hash of database ID, user ID and query text. Hex representation of <code>queryid</code> is in square brackets.	
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
Plan Read Bytes	Bytes read during planning	plan_reads
Exec Read Bytes	Bytes read during execution	exec_reads
Read Bytes %Total	Percentage of <code>plan_reads</code> + <code>exec_reads</code> in the total number of bytes read by the filesystem layer for all statements	
Plan Writes	Bytes written during planning	plan_writes
Exec Writes	Bytes written during execution	exec_writes
Write %Total	Percentage of <code>plan_writes</code> + <code>exec_writes</code> in the total number of bytes written by the filesystem layer for all statements	

### F.35.10.4. SQL query wait statistics

If the `pgpro_stats` extension was available during the report interval, this section of the report will contain a table that is split into sections, each showing top statements by overall wait time or by wait time for a certain [wait event type](#). Table sections related to specific wait events follow in the descending order of the total wait time in wait events of this type. [Table F.46](#) lists columns of this report table. Times are provided in seconds.

**Table F.46. SQL query wait statistics**

Column	Description	Field/Calculation
Query ID	Query identifier, as a hash of database ID, user ID and query text. Hex representation of queryid is in square brackets.	
Plan ID	Hash of the statement plan	planid
Database	Database name for the statement	Derived from dbid
Waited	Total wait time for all wait events of this statement plan	
%Total	Percentage of the total wait time of this statement plan in all the wait time in the cluster	
Details	Waits of this statement plan by wait types	

### F.35.10.5. Complete list of SQL texts

The "Complete list of SQL texts" section of the report contains a table that provides query and plan texts for all statements mentioned in the report. Use an appropriate `Query ID/Plan ID` link in any statistics table to see the corresponding query/plan text. [Table F.47](#) lists columns of this report table.

**Table F.47. Complete list of SQL texts**

Column	Description
ID	Query or plan identifier
Query/Plan Text	Text of the query or statement plan

### F.35.10.6. Schema object statistics

Tables in this section of the report show top database objects by statistics from the Postgres Pro's [Statistics Collector](#) views.

The report table "Top tables by estimated sequentially scanned volume" shows top tables by estimated volume read by sequential scans. This can help you find database tables that possibly lack some index. When there are no relation sizes collected with `pg_relation_size()`, relation-size estimates are based on the `pg_class.relpages` field. Since such values are less accurate, they are shown in square brackets. The data is based on the `pg_stat_all_tables` view. [Table F.48](#) lists columns of this report table.

**Table F.48. Top tables by estimated sequentially scanned volume**

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	

Column	Description	Field/Calculation
Table	Table name	
~SeqBytes	Estimated volume read by sequential scans	Sum of (pg_relation_size() * seq_scan )
SeqScan	Number of sequential scans performed on the table	seq_scan
IxScan	Number of index scans initiated on the table	idx_scan
IxFet	Number of live rows fetched by index scans	idx_tup_fetch
Ins	Number of rows inserted	n_tup_ins
Upd	Number of rows updated	n_tup_upd
Del	Number of rows deleted	n_tup_del
Upd (HOT)	Number of rows HOT updated	n_tup_hot_upd

In the report table “Top tables by blocks fetched”, blocks fetched include blocks being processed from disk (read) and from shared buffers (hit). This report table shows top database tables by the sum of blocks fetched for the table's heap, indexes, TOAST table (if any) and TOAST table index (if any). This can help you focus on tables with excessive processing of blocks. The data is based on the [pg\\_statio\\_all\\_tables](#) view. [Table F.49](#) lists columns of this report table.

**Table F.49. Top tables by blocks fetched**

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Heap Blks	Number of blocks fetched for the table's heap	heap_blks_read + heap_blks_hit
Heap Blks %Total	Percentage of blocks fetched for the table's heap in all blocks fetched in the cluster	
Ix Blks	Number of blocks fetched for table's indexes	idx_blks_read + idx_blks_hit
Ix Blks %Total	Percentage of blocks fetched for table's indexes in all blocks fetched in the cluster	
TOAST Blks	Number of blocks fetched for the table's TOAST table	toast_blks_read + toast_blks_hit
TOAST Blks %Total	Percentage of blocks fetched for the table's TOAST table in all blocks fetched in the cluster	
TOAST-Ix Blks	Number of blocks fetched for the table's TOAST index	tidx_blks_read + tidx_blks_hit
TOAST-Ix Blks %Total	Percentage of blocks fetched for the table's TOAST index in all blocks fetched in the cluster	

The report table “Top tables by blocks read” shows top database tables by the number of blocks read for the table's heap, indexes, TOAST table (if any) and TOAST table index (if any). This can help you focus on tables with excessive block readings. The data is based on the [pg\\_statio\\_all\\_tables](#) view. [Table F.50](#) lists columns of this report table.

**Table F.50. Top tables by blocks read**

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Heap Blks	Number of blocks read for the table's heap	heap_blks_read
Heap Blks %Total	Percentage of blocks read from the table's heap in all blocks read in the cluster	
Ix Blks	Number of blocks read from table's indexes	idx_blks_read
Ix Blks %Total	Percentage of blocks read from table's indexes in all blocks read in the cluster	
TOAST Blks	Number of blocks read from the table's TOAST table	toast_blks_read
TOAST Blks %Total	Percentage of blocks read from the table's TOAST table in all blocks read in the cluster	
TOAST-Ix Blks	Number of blocks read from the table's TOAST index	tidx_blks_read
TOAST-Ix Blks %Total	Percentage of blocks read from the table's TOAST index in all blocks read in the cluster	
Hit (%)	Percentage of table, index, TOAST and TOAST index blocks got from buffers for this table in all blocks got for this table from either file system or buffers	

The report table “Top DML tables” shows top tables by the number of DML-affected rows, i.e., by the sum of `n_tup_ins`, `n_tup_upd` and `n_tup_del` (including TOAST tables). The data is based on the [pg\\_stat\\_all\\_tables](#) view. [Table F.51](#) lists columns of this report table.

**Table F.51. Top DML tables**

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Ins	Number of rows inserted	n_tup_ins

Column	Description	Field/Calculation
Upd	Number of rows updated, including HOT	n_tup_upd
Del	Number of rows deleted	n_tup_del
Upd (HOT)	Number of rows HOT updated	n_tup_hot_upd
SeqScan	Number of sequential scans performed on the table	seq_scan
SeqFet	Number of live rows fetched by sequential scans	seq_tup_read
IxScan	Number of index scans initiated on this table	idx_scan
IxFet	Number of live rows fetched by index scans	idx_tup_fetch

The report table “Top tables by updated/deleted tuples” shows top tables by tuples modified by UPDATE/DELETE operations, i.e., by the sum of `n_tup_upd` and `n_tup_del` (including TOAST tables). The data is based on the `pg_stat_all_tables` view. Table F.52 lists columns of this report table.

**Table F.52. Top tables by updated/deleted tuples**

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Upd	Number of rows updated, including HOT	n_tup_upd
Upd (HOT)	Number of rows HOT updated	n_tup_hot_upd
Del	Number of rows deleted	n_tup_del
Vacuum	Number of times this table has been manually vacuumed (not counting VACUUM FULL)	vacuum_count
AutoVacuum	Number of times this table has been vacuumed by the autovacuum daemon	autovacuum_count
Analyze	Number of times this table was manually analyzed	analyze_count
AutoAnalyze	Number of times this table was analyzed by the autovacuum daemon	autoanalyze_count

The report table “Top growing tables” shows top tables by growth. The data is based on the `pg_stat_all_tables` view. When there are no relation sizes collected with `pg_relation_size()`, relation-size estimates are based on the `pg_class.relpages` field. Since such values are less accurate, they are shown in square brackets. Table F.53 lists columns of this report table.

**Table F.53. Top growing tables**

Column	Description	Field/Calculation
DB	Database name for the table	

Column	Description	Field/Calculation
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Size	Table size at the time of the last sample in the report interval	<code>pg_table_size()</code> - <code>pg_relation_size(toast)</code>
Growth	Table growth	
Ins	Number of rows inserted	<code>n_tup_ins</code>
Upd	Number of rows updated, including HOT	<code>n_tup_upd</code>
Del	Number of rows deleted	<code>n_tup_del</code>
Upd (HOT)	Number of rows HOT updated	<code>n_tup_hot_upd</code>

In the report table “Top indexes by blocks fetched”, blocks fetched include index blocks processed from disk (read) and from shared buffers (hit). The data is based on the `pg_statio_all_indexes` view. Table F.54 lists columns of this report table.

**Table F.54. Top indexes by blocks fetched**

Column	Description	Field/Calculation
DB	Database name for the index	
Tablespace	Name of the tablespace where the index is located	
Schema	Schema name for the underlying table	
Table	Underlying table name	
Index	Index name	
Scans	Number of index scans initiated on this index	<code>idx_scan</code>
Blks	Number of blocks fetched for this index	<code>idx_blks_read</code> + <code>idx_blks_hit</code>
%Total	Percentage of blocks fetched for this index in all blocks fetched in the cluster	

The report table “Top indexes by blocks read” is also based on the `pg_statio_all_indexes` and `pg_stat_all_indexes` views. Table F.55 lists columns of this report table.

**Table F.55. Top indexes by blocks read**

Column	Description	Field/Calculation
DB	Database name for the index	
Tablespace	Name of the tablespace where the index is located	
Schema	Schema name for the underlying table	
Table	Underlying table name	
Index	Index name	

Column	Description	Field/Calculation
Scans	Number of index scans initiated on this index	idx_scan
Blk Reads	Number of disk blocks read from this index	idx_blks_read
%Total	Percentage of disk blocks read from this index in all disk blocks read in the cluster	
Hits(%)	Percentage of index blocks got from buffers in all index blocks got for this index	

The report table “Top growing indexes” shows top indexes by growth. The table uses data from the `pg_stat_all_tables` and `pg_stat_all_indexes` views. When there are no relation sizes collected with `pg_relation_size()`, relation-size estimates are based on the `pg_class.relpages` field. Since such values are less accurate, they are shown in square brackets. Table F.56 lists columns of this report table.

**Table F.56. Top growing indexes**

Column	Description	Field/Calculation
DB	Database name for the index	
Tablespace	Name of the tablespace where the index is located	
Schema	Schema name for the underlying table	
Table	Underlying table name	
Index	Index name	
Index Size	Index size at the time of the last sample in the report interval	<code>pg_relation_size()</code>
Index Growth	Index growth during the report interval	
Table Ins	Number of rows inserted into the underlying table	<code>n_tup_ins</code>
Table Upd	Number of rows updated in the underlying table, without HOT	<code>n_tup_upd - n_tup_hot_upd</code>
Table Del	Number of rows deleted from the underlying table	<code>n_tup_del</code>

The report table “Unused indexes” shows top non-scanned indexes (during the report interval) by DML operations on underlying tables that caused index support. Constraint indexes are not counted. The table uses data from the `pg_stat_all_tables` view. Table F.57 lists columns of this report table.

**Table F.57. Unused indexes**

Column	Description	Field/Calculation
DB	Database name for the index	
Tablespace	Name of the tablespace where the index is located	
Schema	Schema name for the underlying table	
Table	Underlying table name	
Index	Index name	

Column	Description	Field/Calculation
Index Size	Index size at the time of the last sample in the report interval	pg_relation_size()
Index Growth	Index growth during the report interval	
Table Ins	Number of rows inserted into the underlying table	n_tup_ins
Table Upd	Number of rows updated in the underlying table, without HOT	n_tup_upd - n_tup_hot_upd
Table Del	Number of rows deleted from the underlying table	n_tup_del

### F.35.10.7. User function statistics

Tables in this section of the report show top functions in the cluster by statistics from the `pg_stat_user_functions` view. Times in the tables are provided in seconds.

The report table “Top functions by total time” shows top functions by the total time elapsed. The report table “Top functions by executions” shows top functions by the number of executions. The report table “Top trigger functions by total time” shows top trigger functions by the total time elapsed. [Table F.58](#) lists columns of these report tables.

**Table F.58. User function statistics**

Column	Description	Field/Calculation
DB	Database name for the function	
Schema	Schema name for the function	
Function	Function name	
Executions	Number of times this function has been called	calls
Total Time (s)	Total time spent in this function and all other functions called by it	total_time
Self Time (s)	Total time spent in this function itself, not including other functions called by it	self_time
Mean Time (s)	Mean time of a single function execution	total_time /calls
Mean self Time (s)	Mean self time of a single function execution	self_time /calls

### F.35.10.8. Vacuum-related statistics

The report table “Top tables by vacuum time spent” is available if `pgpro_stats` can provide extended vacuum statistics. This table shows top tables by total time spent vacuuming them. The data is based on the `pgpro_stats_vacuum_tables` view. [Table F.59](#) lists columns of this report table.

**Table F.59. Top tables by vacuum time spent**

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	

Column	Description	Field/Calculation
Table	Table name	
Total vacuum time	Total time of vacuuming this table	total_time
Delay vacuum time	Time spent sleeping in a vacuum delay point by vacuum operations performed on this table	delay_time
Read I/O time	Time spent reading database blocks by vacuum operations performed on this table	blk_read_time
Write I/O time	Time spent writing database blocks by vacuum operations performed on this table	blk_write_time
User CPU time	User CPU time of vacuuming tables of this database	user_time
System CPU time	System CPU time of vacuuming tables of this database	system_time
Vacuum count	Number of times this table has been manually vacuumed (not counting VACUUM FULL)	vacuum_count
Autovacuum count	Number of times this table has been vacuumed by the autovacuum daemon	autovacuum_count
Total fetched	Total number of database blocks fetched by vacuum operations performed on this table	total_blks_read + total_blks_hit
Heap fetched	Total number of blocks fetched from this table by vacuum operations performed on it	rel_blks_read + rel_blks_hit
Scanned	Number of pages examined by vacuum operations performed on this table	pages_scanned

The report table “Top tables by blocks vacuum fetched” is available if [pgpro\\_stats](#) can provide extended vacuum statistics. This table shows top tables by blocks fetched vacuuming these tables. The data is based on the `pgpro_stats_vacuum_tables` view. [Table F.60](#) lists columns of this report table.

**Table F.60. Top tables by blocks vacuum fetched**

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
DB fetched	Total number of database blocks fetched by vacuum operations performed on this table	total_blks_read + total_blks_hit
%Total	Total number of database blocks fetched by vacuum operations	

Column	Description	Field/Calculation
	performed on this table as the percentage of all blocks fetched in the cluster	
DB read	Total number of database blocks read by vacuum operations performed on this table	total_blks_read
%Total	Total number of database blocks read by vacuum operations performed on this table as the percentage of all blocks read in the cluster	
Heap fetched	Total number of blocks fetched from this table by vacuum operations performed on it	rel_blks_read + rel_blks_hit
%Rel	Total number of table blocks fetched by vacuum operations performed on this table as the percentage of all blocks fetched from this table	
Heap read	Total number of blocks read from this table by vacuum operations performed on it	rel_blks_read
%Rel	Total number of table blocks read by vacuum operations performed on this table as the percentage of all blocks read from this table	
Scanned	Number of pages examined by vacuum operations performed on this table	pages_scanned

The report table “Top indexes by blocks vacuum fetched” is available if `pgpro_stats` can provide extended vacuum statistics. This table shows top indexes by blocks fetched vacuuming underlying tables. The data is based on the `pgpro_stats_vacuum_indexes` view. [Table F.61](#) lists columns of this report table.

**Table F.61. Top indexes by blocks vacuum fetched**

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Index	Index name	
DB fetched	Total number of database blocks fetched by vacuum operations performed on this index	total_blks_read + total_blks_hit
%Total	Total number of database blocks fetched by vacuum operations performed on this index as the percentage of all blocks fetched in the cluster	

Column	Description	Field/Calculation
DB read	Total number of database blocks read by vacuum operations performed on this index	total_blks_read
%Total	Total number of database blocks read by vacuum operations performed on this index as the percentage of all blocks read in the cluster	
Idx fetched	Total number of blocks fetched from this index by vacuum operations on it	rel_blks_read + rel_blks_hit
%Idx	Total number of index blocks fetched by vacuum operations performed on this index as the percentage of all blocks fetched from this index	
Idx read	Total number of blocks read from this index by vacuum operations performed on it	rel_blks_read
%Idx	Total number of index blocks read by vacuum operations performed on this index as the percentage of all blocks read from this index	

The report table “Top tables by blocks vacuum read” is available if [pgpro\\_stats](#) can provide extended vacuum statistics. This table shows top tables by blocks read vacuuming these tables. The data is based on the `pgpro_stats_vacuum_indexes` view. [Table F.62](#) lists columns of this report table.

**Table F.62. Top tables by blocks vacuum read**

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
DB read	Total number of database blocks read by vacuum operations performed on this table	total_blks_read
%Total	Total number of database blocks read by vacuum operations performed on this table as the percentage of all blocks read in the cluster	
%Hit	Total number of database blocks found in shared buffers by vacuum operations performed on this table as the percentage of all blocks fetched by vacuum operations performed on this table	

Column	Description	Field/Calculation
Heap read	Total number of database blocks vacuum operations read from this table	rel_blks_read
%Rel	Total number of table blocks read by vacuum operations performed on this table as the percentage of all blocks read from this table	
%Hit	Total number of table blocks found in shared buffers by vacuum operations performed on this table as the percentage of table blocks fetched by vacuum operations performed on this table	
Scanned	Number of pages examined by vacuum operations performed on this table	pages_scanned

The report table “Top indexes by blocks vacuum read” is available if [pgpro\\_stats](#) can provide extended vacuum statistics. This table shows top indexes by blocks read vacuuming underlying tables. The data is based on the `pgpro_stats_vacuum_indexes` view. [Table F.63](#) lists columns of this report table.

**Table F.63. Top indexes by blocks vacuum read**

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Index	Index name	
DB read	Total number of database blocks read by vacuum operations performed on this index	total_blks_read
%Total	Total number of database blocks read by vacuum operations performed on this index as the percentage of all blocks read in the cluster	
%Hit	Total number of database blocks found in shared buffers by vacuum operations performed on this index as the percentage of all database blocks fetched by vacuum operations performed on this index	
Idx read	Total number of blocks read from this index by vacuum operations performed on it	rel_blks_read
%Idx	Total number of index blocks read by vacuum operations	

Column	Description	Field/Calculation
	performed on this index as the percentage of all blocks read from this index	
%Hit	Total number of index blocks found in shared buffers by vacuum operations performed on this index as the percentage of index blocks fetched by vacuum operations performed on this index	

The report table “Top tables by dead tuples vacuum left” is available if `pgpro_stats` can provide extended vacuum statistics. This table shows top tables by the number of dead tuples left by vacuum due to their visibility in transactions. The data is based on the `pgpro_stats_vacuum_tables` view. [Table F.64](#) lists columns of this report table.

**Table F.64. Top tables by dead tuples vacuum left**

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Dead tuples left	Total number of dead tuples vacuum operations left in this table due to their visibility in transactions	<code>dead_tuples</code>
Dead tuples deleted	Total number of dead tuples vacuum operations deleted from this table	<code>tuples_deleted</code>
%Eff	Vacuum efficiency in terms of deleted tuples. This is the percentage of dead tuples deleted from this table in all dead tuples to be deleted from this table.	$\text{tuples\_deleted} * 100 / (\text{tuples\_deleted} + \text{dead\_tuples})$
Tuples del	Number of rows deleted	<code>pg_stat_all_tables .n_tup_del</code>
Tuples upd	Number of rows updated ( includes HOT updated rows)	<code>pg_stat_all_tables .n_tup_upd</code>
Vacuum	Number of times this table has been manually vacuumed (not counting <code>VACUUM FULL</code> )	<code>vacuum_count</code>
Autovacuum	Number of times this table has been vacuumed by the autovacuum daemon	<code>autovacuum_count</code>

The report table “Top tables by WAL size generated by vacuum” is available if `pgpro_stats` can provide extended vacuum statistics. This table shows top tables by the amount of WAL generated by vacuum operations performed on them. The data is based on the `pgpro_stats_vacuum_tables` view. [Table F.65](#) lists columns of this report table.

**Table F.65. Top tables by WAL size generated by vacuum**

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
WAL size	Total amount of WAL bytes generated by vacuum operations performed on this table	wal_bytes
%Total	Total amount of WAL bytes generated by vacuum operations performed on this table as the percentage of all WAL generated in the cluster	
WAL FPI	Total number of WAL full page images generated by vacuum operations performed on this table	wal_fpi
Scanned blocks	Number of pages examined by vacuum operations performed on this table	pages_scanned
Dirtied blocks	Number of database blocks dirtied by vacuum operations performed on this table	total_blks_dirtied
Removed blocks	Number of pages removed by vacuum operations performed on this table	pages_removed
Vacuum	Number of times this table has been manually vacuumed (not counting VACUUM FULL)	vacuum_count
Autovacuum	Number of times this table has been vacuumed by the autovacuum daemon	autovacuum_count

The report table “Top tables by vacuum operations” shows top tables by the number of vacuum operations performed (`vacuum_count + autovacuum_count`). The data is based on the `pg_stat_all_tables` view. [Table F.66](#) lists columns of this report table.

**Table F.66. Top tables by vacuum operations**

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Vacuum count	Number of times this table has been manually vacuumed (not counting VACUUM FULL)	vacuum_count

Column	Description	Field/Calculation
Autovacuum count	Number of times this table has been vacuumed by the autovacuum daemon	autovacuum_count
Ins	Number of rows inserted	n_tup_ins
Upd	Number of rows updated (includes HOT updated rows)	n_tup_upd
Del	Number of rows deleted	n_tup_del
Upd (HOT)	Number of rows HOT updated	n_tup_hot_upd

The report table “Top tables by analyze operations” shows top tables by the number of analyze operations performed (`analyze_count + autoanalyze_count`). The data is based on the `pg_stat_all_tables` view. [Table F.67](#) lists columns of this report table.

**Table F.67. Top tables by analyze operations**

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Analyze count	Number of times this table has been manually analyzed	analyze_count
Autoanalyze count	Number of times this table has been analyzed by the autovacuum daemon	autoanalyze_count
Ins	Number of rows inserted	n_tup_ins
Upd	Number of rows updated, including HOT	n_tup_upd
Del	Number of rows deleted	n_tup_del
Upd (HOT)	Number of rows HOT updated	n_tup_hot_upd

The report table “Top indexes by estimated vacuum load” shows top indexes by estimated implicit vacuum load. This load is calculated as the number of vacuum operations performed on the underlying table multiplied by the index size. The data is based on the `pg_stat_all_indexes` view. When there are no relation sizes collected with `pg_relation_size()`, relation-size estimates are based on the `pg_class.relpages` field. Since such values are less accurate, they are shown in square brackets. [Table F.68](#) lists columns of this report table.

**Table F.68. Top indexes by estimated vacuum load**

Column	Description	Field/Calculation
DB	Database name for the index	
Tablespace	Name of the tablespace where the index is located	
Schema	Schema name for the underlying table	
Table	Underlying table name	
Index	Index name	

Column	Description	Field/Calculation
~Vacuum bytes	Vacuum load estimation	$(\text{vacuum\_count} + \text{autovacuum\_count}) * \text{index\_size}$
Vacuum count	Number of times this table has been manually vacuumed (not counting VACUUM FULL)	vacuum_count
Autovacuum count	Number of times this table has been vacuumed by the autovacuum daemon	autovacuum_count
IX size	Average index size during the report interval	
Relsize	Average relation size during the report interval	

The report table “Top tables by dead tuples ratio” shows top tables larger than 5 MB by the ratio of dead tuples. Statistics are valid for the last sample in the report interval. The data is based on the `pg_stat_all_tables` view. When there are no relation sizes collected with `pg_relation_size()`, relation-size estimates are based on the `pg_class.relpages` field. Since such values are less accurate, they are shown in square brackets. [Table F.69](#) lists columns of this report table.

**Table F.69. Top tables by dead tuples ratio**

Column	Description	Field/Calculation
DB	Database name for the table	
Schema	Schema name for the table	
Table	Table name	
Live	Estimated number of live rows	n_live_tup
Dead	Estimated number of dead rows	n_dead_tup
%Dead	Percentage of dead rows in all table rows	
Last AV	Last time at which this table was vacuumed by the autovacuum daemon	last_autovacuum
Size	Table size	$\text{pg\_table\_size}() - \text{pg\_relation\_size}(\text{toast})$

The report table “Top tables by modified tuples ratio” shows top tables larger than 5 MB by the ratio of modified tuples. Statistics are valid for the last sample in the report interval. The data is based on the `pg_stat_all_tables` view. When there are no relation sizes collected with `pg_relation_size()`, relation-size estimates are based on the `pg_class.relpages` field. Since such values are less accurate, they are shown in square brackets. [Table F.70](#) lists columns of this report table.

**Table F.70. Top tables by modified tuples ratio**

Column	Description	Field/Calculation
DB	Database name for the table	
Schema	Schema name for the table	
Table	Table name	
Live	Estimated number of live rows	n_live_tup
Dead	Estimated number of dead rows	n_dead_tup

Column	Description	Field/Calculation
Mod	Estimated number of rows modified since this table was last analyzed	n_mod_since_analyze
%Mod	Percentage of modified rows in all table rows	
Last AA	Last time at which this table was analyzed by the autovacuum daemon	last_autoanalyze
Size	Table size	pg_table_size() - pg_relation_size(toast)

### F.35.10.9. Cluster settings during the report interval

This section of the report contains a table with Postgres Pro GUC parameters, values of functions `version()`, `pg_postmaster_start_time()`, `pg_conf_load_time()` and the `system_identifier` field of the `pg_control_system()` function during the report interval. The data in the table is grouped under `Defined settings` and `Default settings`. [Table F.71](#) lists columns of this report table.

**Table F.71. Cluster settings during the report interval**

Column	Description
Setting	Name of the parameter
reset_val	reset_val field of the <code>pg_settings</code> view. Settings changed during the report interval are shown in bold font.
Unit	Unit of the setting
Source	Configuration file where this setting is defined, semicolon, line number
Notes	Timestamp of the sample where this value was first observed

### F.35.11. pgpro\_pwr Diagnostic Tools

`pgpro_pwr` provides self-diagnostic tools.

#### F.35.11.1. Collecting Detailed Timing Statistics for Sampling Procedures

`pgpro_pwr` collects detailed timing statistics of taking samples when the `pgpro_pwr.track_sample_timings` parameter is on. You can get the results from the `v_sample_timings` view. [Table F.72](#) lists columns of this view.

**Table F.72. v\_sample\_timings View**

Column	Description
server_name	Name of the server
sample_id	Sample identifier
sample_time	Time when the sample was taken
sampling_event	Sampling stage. See <a href="#">Table F.73</a> for descriptions of sampling stages.
time_spent	Time spent in the event

**Table F.73. sampling\_event Description**

Event	Description
total	Taking the sample (all stages)

Event	Description
connect	Making dblink connection to the server
get server environment	Getting server GUC parameters, available extensions, etc.
collect database stats	Querying the <code>pg_stat_database</code> view for statistics on databases
calculate database stats	Calculating differential statistics on databases since the previous sample
collect tablespace stats	Querying the <code>pg_tablespace</code> view for statistics on tablespaces
collect statement stats	Collecting statistics on statements using the <code>pgpro_stats</code> and <code>pg_stat_kcache</code> extensions
query pg_stat_bgwriter	Collecting cluster statistics using the <code>pg_stat_bgwriter</code> view
query pg_stat_archiver	Collecting cluster statistics using the <code>pg_stat_archiver</code> view
collect object stats	Collecting statistics on database objects. Includes events from <a href="#">Table F.74</a> .
maintain repository	Executing support routines
calculate tablespace stats	Calculating differential statistics on tablespaces
calculate object stats	Calculating differential statistics on database objects. Includes events from <a href="#">Table F.75</a> .
calculate cluster stats	Calculating cluster differential statistics
calculate archiver stats	Calculating archiver differential statistics
delete obsolete samples	Deleting obsolete baselines and samples

**Table F.74. Events of Collecting Statistics on Database Objects**

Event	Description
<code>db:dbname collect tables stats</code>	Collecting statistics on tables for the <code>dbname</code> database
<code>db:dbname collect indexes stats</code>	Collecting statistics on indexes for the <code>dbname</code> database
<code>db:dbname collect functions stats</code>	Collecting statistics on functions for the <code>dbname</code> database

**Table F.75. Events of Calculating Differences of Statistics on Database Objects**

Event	Description
<code>calculate tables stats</code>	Calculating differential statistics on tables of all databases
<code>calculate indexes stats</code>	Calculating differential statistics on indexes of all databases
<code>calculate functions stats</code>	Calculating differential statistics on functions of all databases

## F.35.12. Important Notes

When using the `pgpro_pwr` extension, be aware of the following:

- Postgres Pro collects execution statistics *after* the execution is complete. If a single execution of a statement lasts for several samples, it will only affect statistics of the last sample (in which

the execution completed). Besides, statistics on statements that are still running are unavailable. Maintenance processes, such as vacuum and checkpointer, will update the statistics only on completion.

- Resetting any Postgres Pro statistics may affect the accuracy of the next sample.
- Exclusive locks on relations conflict with calculation of the relation size. If the `take_sample()` function is unable to acquire a lock for a short period of time (3 seconds), it will fail and no sample will be generated.

## F.36. pg\_prewarm

The `pg_prewarm` module provides a convenient way to load relation data into either the operating system buffer cache or the Postgres Pro buffer cache. Prewarming can be performed manually using the `pg_prewarm` function, or can be performed automatically by including `pg_prewarm` in [shared\\_preload\\_libraries](#). In the latter case, the system will run a background worker which periodically records the contents of shared buffers in a file called `autoprewarm.blocks` and will, using 2 background workers, reload those same blocks after a restart.

### F.36.1. Functions

```
pg_prewarm(regclass, mode text default 'buffer', fork text default 'main',
           first_block int8 default null,
           last_block int8 default null) RETURNS int8
```

The first argument is the relation to be prewarmed. The second argument is the prewarming method to be used, as further discussed below; the third is the relation fork to be prewarmed, usually `main`. The fourth argument is the first block number to prewarm (`NULL` is accepted as a synonym for zero). The fifth argument is the last block number to prewarm (`NULL` means prewarm through the last block in the relation). The return value is the number of blocks prewarmed.

There are three available prewarming methods. `prefetch` issues asynchronous prefetch requests to the operating system, if this is supported, or throws an error otherwise. `read` reads the requested range of blocks; unlike `prefetch`, this is synchronous and supported on all platforms and builds, but may be slower. `buffer` reads the requested range of blocks into the database buffer cache.

Note that with any of these methods, attempting to prewarm more blocks than can be cached — by the OS when using `prefetch` or `read`, or by Postgres Pro when using `buffer` — will likely result in lower-numbered blocks being evicted as higher numbered blocks are read in. Prewarmed data also enjoys no special protection from cache evictions, so it is possible that other system activity may evict the newly prewarmed blocks shortly after they are read; conversely, prewarming may also evict other data from cache. For these reasons, prewarming is typically most useful at startup, when caches are largely empty.

```
autoprewarm_start_worker() RETURNS void
```

Launch the main autoprewarm worker. This will normally happen automatically, but is useful if automatic prewarm was not configured at server startup time and you wish to start up the worker at a later time.

```
autoprewarm_dump_now() RETURNS int8
```

Update `autoprewarm.blocks` immediately. This may be useful if the autoprewarm worker is not running but you anticipate running it after the next restart. The return value is the number of records written to `autoprewarm.blocks`.

### F.36.2. Configuration Parameters

```
pg_prewarm.autoprewarm (boolean)
```

Controls whether the server should run the autoprewarm worker. This is on by default. This parameter can only be set at server start.

```
pg_prewarm.autoprewarm_interval (int)
```

This is the interval between updates to `autoprewarm.blocks`. The default is 300 seconds. If set to 0, the file will not be dumped at regular intervals, but only when the server is shut down.

### F.36.3. Author

Robert Haas <rhoas@postgresql.org>

## F.37. pgpro\_stats

The `pgpro_stats` extension provides a means for tracking planning and execution statistics of all SQL statements executed by a server. It is based on the [pg\\_stat\\_statements](#) module and provides the following additional functionality:

- Storing query plans in addition to query statements.
- Configuring sample rate for statistics collection to reduce overhead.
- Calculating wait event statistics for executed queries.
- Calculating resource usage statistics of statement planning and execution.
- Calculating cache invalidation statistics.
- Calculating statistics about vacuuming tables and indexes.

### F.37.1. Limitations

- `pgpro_stats` can sometimes fail to match identical parameters in the query statement and the corresponding query plan.
- Some SPI queries are not included into statistics.
- `pgpro_stats` is incompatible with [pg\\_stat\\_statements](#), as well as other extensions that use parser, planner, or executor hooks to modify parse and plan trees and execution of the queries. Note also that in order to dump the final versions of the queries and plans, `pgpro_stats` should be the last on the list of `shared_preload_libraries`, but some existing extensions, such as `pg_pathman`, will not work at all unless they are the last on this list.
- `pgpro_stats` may not work correctly with third-party extensions that produce `CustomScan` and `ForeignScan` nodes.

### F.37.2. Installation and Setup

The `pgpro_stats` extension is included into Postgres Pro Standard, but has to be installed separately. Once you have `pgpro_stats` installed, complete the following steps to enable `pgpro_stats`:

1. Add `pgpro_stats` to the [shared\\_preload\\_libraries](#) parameter in the `postgresql.conf` file:

```
shared_preload_libraries = 'pgpro_stats'
```

2. Restart the Postgres Pro Standard instance for the changes to take effect.

Once the server is reloaded, `pgpro_stats` starts tracking statistics across all databases of the cluster. If required, you can change the scope of statistics collection or disable it altogether using `pgpro_stats` [configuration parameters](#).

3. To access the collected statistics, you have to create `pgpro_stats` extension:

```
CREATE EXTENSION pgpro_stats;
```

### F.37.3. Usage

- [Collecting Statistics on Query Statements and Plans](#)
- [Monitoring Custom Metrics](#)

#### F.37.3.1. Collecting Statistics on Query Statements and Plans

Once installed, the `pgpro_stats` extension starts collecting statistics on the executed statements. The collected data is similar to the one provided by [pg\\_stat\\_statements](#), but also includes information on query plans and wait events for each query type. The statistics is saved into an in-memory ring buffer and is accessible through the [pgpro\\_stats\\_statements](#) view.

By default, `pgpro_stats` collects statistics on all the executed statements that satisfy the `pgpro_stats.track` and `pgpro_stats.track_utility` settings. If performance is a concern, you can set a sample rate for queries using the `pgpro_stats.query_sample_rate` parameter, and `pgpro_stats` will randomly select queries for statistics calculation at the specified rate.

To collect statistics on wait events, `pgpro_stats` uses time-based sampling. Wait events are sampled at the time interval specified by the `pgpro_stats.profile_period` parameter, which is set to 10ms by default. If the sampling shows that the process is waiting, the `pgpro_stats.profile_period` value is added to the wait event duration. Thus, time estimation for each wait event remains valid even if the `pgpro_stats.profile_period` parameter value has changed. If you are not interested in wait event statistics, you can disable wait event sampling by setting the `pgpro_stats.enable_profile` parameter to `false`.

`pgpro_stats_statements.plans` and `pgpro_stats_statements.calls` aren't always expected to match because planning and execution statistics are updated at their respective end phase, and only for successful operations. For example, if a statement is successfully planned but fails during the execution phase, only its planning statistics will be updated. If planning is skipped because a cached plan is used, only its execution statistics will be updated.

As an example, let's create a table with some random data and build an index on this table:

```
CREATE TABLE test AS (SELECT i, random() x FROM generate_series(1,1000000) i);
CREATE INDEX test_x_idx ON test (x);
```

Now run the following query several times using different values for `:x_min` and `:x_max`:

```
select * from test where x >= :x_min and x <= :x_max;
```

The collected statistics should appear in the `pgpro_stats_statements` view:

```
SELECT queryid, query, planid, plan, wait_stats FROM pgpro_stats_statements WHERE query
LIKE 'select * from test where%';
```

```
-[ RECORD
 1 ]-----
queryid      | 1109491335754870054
query        | select * from test where x >= $1 and x <= $2

wait_stats   | NULL

```

### F.37.3.2. Monitoring Custom Metrics

With `pgpro_stats`, you can define custom metrics to be monitored. The collected data will be saved into an in-memory ring buffer and then sent to a monitoring system. Unlike direct polling of a database by a monitoring system that can lose some data if the connection is interrupted, this approach allows to get all the collected data regardless of connection issues, as long as this data is still available in the ring buffer.

To set up a custom metric to collect, do the following:

1. For each metric, define all configuration parameters listed in [Section F.37.7.2](#). You must specify a unique numeric identifier of each metric in the parameter names.

For example, to monitor index bloating each 60 seconds, you can define a new metric by setting metrics-related parameters as follows:

```

pgpro_stats.metric_1_name = index_bloat
pgpro_stats.metric_1_query = 'select iname, ibloat, ipages from bloat'
pgpro_stats.metric_1_db = 'postgres'
pgpro_stats.metric_1_user = postgres
pgpro_stats.metric_1_period = '60s'

```

2. Restart the server.

`pgpro_stats` starts collecting statistics on executed statements and saves it into the ring buffer, and the collected data appears in the `pgpro_stats_metrics` view:

```
SELECT * FROM pgpro_stats_metrics;
```

Once the new metric is added, its parameters can be changed without a server restart by simply reloading the `postgresql.conf` configuration file.

3. If required, set up data export to a monitoring system of your choice.

## F.37.4. Views

### F.37.4.1. The `pgpro_stats_statements` View

The statistics gathered by the module are made available via a view named `pgpro_stats_statements`. This view contains one row for each distinct database ID, user ID and query ID (up to the maximum number of distinct statements that the module can track). The columns of the view are shown in [Table F.76](#).

**Table F.76. pgpro\_stats\_statements Columns**

<b>Name</b>	<b>Type</b>	<b>References</b>	<b>Description</b>
userid	oid	<a href="#">pg_authid</a> .oid	OID of user who executed the statement
dbid	oid	<a href="#">pg_database</a> .oid	OID of database in which the statement was executed
queryid	bigint		Internal hash code, computed from the statement's parse tree
planid	bigint		Internal hash code, computed from the statement's plan tree
query	text		Text of a representative statement
plan	text		The text of the query plan, in the format defined by the <a href="#">pgpro_stats.plan_format</a> configuration parameter
plans	int8		Number of times the statement was planned (if <code>pgpro_stats.track_planning</code> is enabled, otherwise zero)
total_plan_time	float8		Total time spent planning the statement, in milliseconds (if <code>pgpro_stats.track_planning</code> is enabled, otherwise zero).
min_plan_time	float8		Minimum time spent planning the statement, in milliseconds (if <code>pgpro_stats.track_planning</code> is enabled, otherwise zero)
max_plan_time	float8		Maximum time spent planning the statement, in milliseconds (if <code>pgpro_stats.track_planning</code> is enabled, otherwise zero)
mean_plan_time	float8		Mean time spent planning the statement, in milliseconds (if <code>pgpro_stats.track_planning</code> is enabled, otherwise zero)
stddev_plan_time	float8		Population standard deviation of time spent planning the statement,

Name	Type	References	Description
			in milliseconds (if <code>pgpro_stats.track_planning</code> is enabled, otherwise zero)
<code>plan_rusage</code>	<a href="#">pgpro_stats_rusage</a>		Resource usage statistics of the statement planning.
<code>calls</code>	<code>int8</code>		Number of times the statement was executed
<code>total_exec_time</code>	<code>float8</code>		Total time spent executing the statement, in milliseconds
<code>min_exec_time</code>	<code>float8</code>		Minimum time spent executing the statement, in milliseconds
<code>max_exec_time</code>	<code>float8</code>		Maximum time spent executing the statement, in milliseconds
<code>mean_exec_time</code>	<code>float8</code>		Mean time spent executing the statement, in milliseconds
<code>stddev_exec_time</code>	<code>float8</code>		Population standard deviation of time spent executing the statement, in milliseconds
<code>exec_rusage</code>	<a href="#">pgpro_stats_rusage</a>		Resource usage statistics of the statement execution.
<code>rows</code>	<code>int8</code>		Total number of rows retrieved or affected by the statement
<code>shared_blks_hit</code>	<code>int8</code>		Total number of shared block cache hits by the statement
<code>shared_blks_read</code>	<code>int8</code>		Total number of shared blocks read by the statement
<code>shared_blks_dirtied</code>	<code>int8</code>		Total number of shared blocks dirtied by the statement
<code>shared_blks_written</code>	<code>int8</code>		Total number of shared blocks written by the statement
<code>local_blks_hit</code>	<code>int8</code>		Total number of local block cache hits by the statement
<code>local_blks_read</code>	<code>int8</code>		Total number of local blocks read by the statement

Name	Type	References	Description
local_blks_dirtied	int8		Total number of local blocks dirtied by the statement
local_blks_written	int8		Total number of local blocks written by the statement
temp_blks_read	int8		Total number of temp blocks read by the statement
temp_blks_written	int8		Total number of temp blocks written by the statement
blk_read_time	float8		Total time the statement spent reading blocks, in milliseconds (if <a href="#">track_io_timing</a> is enabled, otherwise zero)
blk_write_time	float8		Total time the statement spent writing blocks, in milliseconds (if <a href="#">track_io_timing</a> is enabled, otherwise zero)
wal_records	int8		Total number of WAL records generated by the statement
wal_fpi	int8		Total number of WAL full page images generated by the statement
wal_bytes	numeric		Total amount of WAL bytes generated by the statement
wait_stats	jsonb		A <code>jsonb</code> object containing statistics on wait events, for each execution of the query that uses the corresponding plan
inval_msgs	<a href="#">pgpro_stats_inval_msgs</a>		Number of cache invalidation messages by type generated by the statement (if this is supported by the server, otherwise zero)

#### F.37.4.2. The `pgpro_stats_totals` View

The aggregate statistics gathered by the module are made available via a view named `pgpro_stats_totals`. This view contains one row for each distinct object (up to the maximum number of distinct objects that the module can track). The columns of the view are shown in [Table F.77](#).

**Table F.77. pgpro\_stats\_totals Columns**

Name	Type	Description
object_type	text	Type of the object for which aggregated statistics are collected: "cluster", "database", "user", "client_addr", "application", "backend", "session"
object_id	bigint	ID of the object: oid for databases and users, pid for backends, sid for sessions, NULL for others
object_name	text	Textual name of the object or NULL
queries_planned	int8	Number of queries planned
total_plan_time	float8	Total time spent in the planning of statements, in milliseconds
total_plan_rusage	<a href="#">pgpro_stats_rusage</a>	Aggregate resource usage statistics of the statement planning
queries_executed	int8	Number of queries executed
total_exec_time	float8	Total time spent in the execution of statements, in milliseconds
total_exec_rusage	<a href="#">pgpro_stats_rusage</a>	Aggregate resource usage statistics of the statement execution
rows	int8	Total number of rows retrieved or affected by the statements
shared_blks_hit	int8	Total number of shared block cache hits by the statements
shared_blks_read	int8	Total number of shared blocks read by the statements
shared_blks_dirtied	int8	Total number of shared blocks dirtied by the statements
shared_blks_written	int8	Total number of shared blocks written by the statements
local_blks_hit	int8	Total number of local block cache hits by the statements
local_blks_read	int8	Total number of local blocks read by the statements
local_blks_dirtied	int8	Total number of local blocks dirtied by the statements
local_blks_written	int8	Total number of local blocks written by the statements
temp_blks_read	int8	Total number of temp blocks read by the statements
temp_blks_written	int8	Total number of temp blocks written by the statements

Name	Type	Description
blk_read_time	float8	Total time the statements spent reading blocks, in milliseconds (if <a href="#">track_io_timing</a> is enabled, otherwise zero)
blk_write_time	float8	Total time the statements spent writing blocks, in milliseconds (if <a href="#">track_io_timing</a> is enabled, otherwise zero)
wal_records	int8	Total number of WAL records generated by the statements
wal_fpi	int8	Total number of WAL full page images generated by the statements
wal_bytes	numeric	Total amount of WAL bytes generated by the statements
wait_stats	jsonb	A jsonb object containing statistics on wait events for each execution of the queries
inval_msgs	<a href="#">pgpro_stats_inval_msgs</a>	Number of cache invalidation messages by type generated by the statements (if this is supported by the server, otherwise zero)
cache_resets	int4	Number of shared cache resets (only for cluster, databases and backends)

### F.37.4.3. The `pgpro_stats_inval_status` View

The `pgpro_stats_inval_status` view shows one row with the current status of the global cache invalidation queue. The columns of the view are shown in [Table F.78](#).

**Table F.78.** `pgpro_stats_inval_status` Columns

Name	Type	Description
num_inval_messages	int8	Number of invalidation messages in the queue
num_inval_queue_cleanups	int8	Number of invalidation queue cleanups done to prevent its overflow
num_inval_queue_resets	int4	Number of cache resets for backends that delay the queue cleanup

In a working system, `num_inval_messages` usually approximately equals 4000, which means that the queue is pretty full. Growing `num_inval_queue_cleanups` indicates an active generation of messages. Growth of `num_inval_queue_resets` is normally zero, and a non-zero growth indicates either a too fast generation of messages or delays in processing messages by backends. You can see reset counters for each backend in the `cache_resets` column of the [pgpro\\_stats\\_totals](#) view.

### F.37.4.4. The `pgpro_stats_metrics` View

The metrics gathered by `pgpro_stats` are displayed in the `pgpro_stats_metrics` view. The table below describes the columns of the view.

**Table F.79. pgpro\_stats\_metrics Columns**

Name	Type	Description
metric_number	int4	A unique ID of the collected metric assigned by user. This ID is included into parameter names that define the metric.
metric_name	text	The name of the metric defined by the <code>pgpro_stats.metric_N_name</code> parameter.
db_name	text	The name of the database for which a particular metric was collected.
ts	timestampz	The time when the metric value got calculated.
value	jsonb	The result of the query used for metric measurement. It is serialized in <code>jsonb</code> as an array of objects received via <code>to_jsonb( resulting_row )</code> . If an error occurs, a single object is returned that contains <code>code</code> , <code>message</code> , <code>detail</code> , and <code>hint</code> fields.

**F.37.4.5. The pgpro\_stats\_vacuum\_tables View**

The `pgpro_stats_vacuum_tables` view will contain one row for each table in the current database (including TOAST tables), showing statistics about vacuuming that specific table. The table below describes the columns of the view.

**Table F.80. pgpro\_stats\_vacuum\_tables View**

Column	Type	Description
relid	oid	OID of a table
schema	name	Name of the schema this table is in
relname	name	Name of this table
total_blks_read	int8	Number of database blocks read by vacuum operations performed on this table
total_blks_hit	int8	Number of database block buffer cache hits by vacuum operations performed on this table
total_blks_dirtied	int8	Number of database blocks dirtied by vacuum operations performed on this table
total_blks_written	int8	Number of database blocks written by vacuum operations performed on this table
rel_blks_read	int8	Number of blocks vacuum operations read from this table
rel_blks_hit	int8	Number of times blocks of this table were already found in

Column	Type	Description
		the buffer cache by vacuum operations, so that a read was not necessary (this only includes hits in the Postgres Pro buffer cache, not the operating system's file system cache)
pages_scanned	int8	Number of pages examined by vacuum operations performed on this table
pages_removed	int8	Number of pages removed from the physical storage by vacuum operations performed on this table
pages_frozen	int8	Number of pages of this table that vacuum operations marked as all-frozen in the visibility map
pages_all_visible	int8	Number of pages of this table that vacuum operations marked as all-visible in the visibility map
tuples_deleted	int8	Number of dead tuples vacuum operations deleted from this table
tuples_frozen	int8	Number of tuples of this table that vacuum operations marked as frozen
dead_tuples	int8	Number of dead tuples vacuum operations left in this table due to their visibility in transactions
wal_records	int8	Total number of WAL records generated by vacuum operations performed on this table
wal_fpi	int8	Total number of WAL full page images generated by vacuum operations performed on this table
wal_bytes	numeric	Total amount of WAL bytes generated by vacuum operations performed on this table
blk_read_time	float8	Time spent reading database blocks by vacuum operations performed on this table, in milliseconds (if <a href="#">track_io_timing</a> is enabled, otherwise zero)
blk_write_time	float8	Time spent writing database blocks by vacuum operations performed on this table, in milliseconds (if <a href="#">track_io_timing</a> is enabled, otherwise zero)
delay_time	float8	Time spent sleeping in a vacuum delay point by vacuum operations performed on this

Column	Type	Description
		table, in milliseconds (see <a href="#">Section 18.4.4</a> for details)
system_time	float8	System CPU time of vacuuming this table, in milliseconds
user_time	float8	User CPU time of vacuuming this table, in milliseconds
total_time	float8	Total time of vacuuming this table, in milliseconds
interrupts	int4	Number of times vacuum operations performed on this table were interrupted on any errors

Columns `total_*`, `wal_*` and `blk_*` include data on vacuuming indexes on this table, while columns `system_time` and `user_time` only include data on vacuuming the heap.

### F.37.4.6. The `pgpro_stats_vacuum_indexes` View

The `pgpro_stats_vacuum_indexes` view will contain one row for each index in the current database (including TOAST table indexes), showing statistics about vacuuming that specific index. The table below describes the columns of the view.

**Table F.81.** `pgpro_stats_vacuum_indexes` View

Column	Type	Description
relid	oid	OID of an index
schema	name	Name of the schema this index is in
relname	name	Name of this index
total_blks_read	int8	Number of database blocks read by vacuum operations performed on this index
total_blks_hit	int8	Number of database block buffer cache hits by vacuum operations performed on this index
total_blks_dirtied	int8	Number of database blocks dirtied by vacuum operations performed on this index
total_blks_written	int8	Number of database blocks written by vacuum operations performed on this index
rel_blks_read	int8	Number of blocks vacuum operations read from this index
rel_blks_hit	int8	Number of times blocks of this index were already found in the buffer cache by vacuum operations, so that a read was not necessary (this only includes hits in the Postgres Pro buffer cache, not the operating system's file system cache)

Column	Type	Description
pages_deleted	int8	Number of pages deleted by vacuum operations performed on this index
tuples_deleted	int8	Number of dead tuples vacuum operations deleted from this index
wal_records	int8	Total number of WAL records generated by vacuum operations performed on this index
wal_fpi	int8	Total number of WAL full page images generated by vacuum operations performed on this index
wal_bytes	numeric	Total amount of WAL bytes generated by vacuum operations performed on this index
blk_read_time	float8	Time spent reading database blocks by vacuum operations performed on this index, in milliseconds (if <a href="#">track_io_timing</a> is enabled, otherwise zero)
blk_write_time	float8	Time spent writing database blocks by vacuum operations performed on this index, in milliseconds (if <a href="#">track_io_timing</a> is enabled, otherwise zero)
delay_time	float8	Time spent sleeping in a vacuum delay point by vacuum operations performed on this index, in milliseconds (see <a href="#">Section 18.4.4</a> for details)
system_time	float8	System CPU time of vacuuming this index, in milliseconds
user_time	float8	User CPU time of vacuuming this index, in milliseconds
total_time	float8	Total time of vacuuming this index, in milliseconds
interrupts	int4	Number of times vacuum operations performed on this index were interrupted on any errors

## F.37.5. Data Types

### F.37.5.1. The `pgpro_stats_rusage` Type

`pgpro_stats_rusage` is a record type that contains resource usage statistics of statement planning/execution. The fields of this type are shown in [Table F.82](#).

**Table F.82. pgpro\_stats\_rusage Fields**

Name	Type	Description
reads	bigint	Number of bytes read by the filesystem layer
writes	bigint	Number of bytes written by the filesystem layer
user_time	double precision	User CPU time used
system_time	double precision	System CPU time used
minflts	bigint	Number of page reclaims (soft page faults)
majflts	bigint	Number of page faults (hard page faults)
nswaps	bigint	Number of swaps
msgsnds	bigint	Number of IPC messages sent
msgrcvd	bigint	Number of IPC messages received
nsignals	bigint	Number of signals received
nvcsws	bigint	Number of voluntary context switches
nivcsws	bigint	Number of involuntary context switches

**F.37.5.2. The pgpro\_stats\_inval\_msgs Type**

pgpro\_stats\_inval\_msgs is a record type containing counters for cache invalidation messages. The fields of the type are shown in [Table F.83](#).

**Table F.83. pgpro\_stats\_inval\_msgs Fields**

Name	Type	Description
total	bigint	Total number of invalidation messages
catcache	bigint	Number of catcache invalidation messages
catalog	bigint	Number of catalog invalidation messages
relcache	bigint	Number of selective relcache invalidation messages
relcache_all	bigint	Number of whole relcache invalidation messages
smgr	bigint	Number of storage manager invalidation messages
relmap	bigint	Number of relation map invalidation messages
snapshot	bigint	Number of snapshot invalidation messages

## F.37.6. Functions

`pgpro_stats_statements_reset`(`userid` `Oid`, `dbid` `Oid`, `queryid` `bigint`, `planid` `bigint`) returns `void`

`pgpro_stats_statements_reset` discards statistics gathered so far by `pgpro_stats` corresponding to the specified `userid`, `dbid`, `queryid`, and `planid`. If any of the parameters are not specified, the default value 0(`invalid`) is used for each of them and the statistics that match with other parameters will be reset. If no parameter is specified or all the specified parameters are 0(`invalid`), it will discard all statistics. By default, this function can only be executed by superusers. Access may be granted to others using `GRANT`.

`pgpro_stats_statements`(`showtext` `boolean`) returns `setof record`

The `pgpro_stats_statements` view is defined in terms of a function also named `pgpro_stats_statements`. Users can also call the `pgpro_stats_statements` function directly, and by specifying `showtext := false` make query text be omitted (that is, the `OUT` argument that corresponds to the view's `query` column will return nulls). This feature is intended to support external tools that might wish to avoid the overhead of repeatedly retrieving query texts of indeterminate length. Such tools can instead cache the first query text observed for each entry themselves, since that is all `pgpro_stats` itself does, and then retrieve query texts only as needed. Since the server stores query texts in a file, this approach may reduce physical I/O for repeated examination of the `pgpro_stats_statements` data.

`pgpro_stats_totals_reset`(`type` `text`, `id` `bigint`) returns `void`

`pgpro_stats_totals_reset` discards statistics gathered so far by `pgpro_stats` corresponding to the specified object `type` and `id`. If no parameter is specified or the `type` parameter is set to 0, all statistics will be discarded. If `type` is set to a valid object type, then if `id` is specified, then statistics will be discarded only for the specified object, else, statistics will be discarded for all objects of the specified type. Otherwise, no statistics will be discarded. By default, this function can only be executed by superusers. Access may be granted to others using `GRANT`.

`pgpro_stats_totals`() returns `setof record`

The `pgpro_stats_totals` view is defined in terms of a function also named `pgpro_stats_totals`. Users can also call the `pgpro_stats_totals` function directly.

`pgpro_stats_metrics`(`showtext` `boolean`) returns `setof record`

Defines the `pgpro_stats_metrics` view, which is described in detail in [Table F.79](#).

`pgpro_stats_wal_sender_crc_errors`() returns `bigint`

Returns zero in Postgres Pro and is fully functional in Postgres Pro Enterprise.

`pgpro_stats_vacuum_tables`(`dboid` `oid`, `relid` `oid`) returns `setof record`

Defines the row of the `pgpro_stats_vacuum_tables` view, which is described in detail in [Table F.80](#), for the database specified by `dboid` and table specified by `relid`. If `relid = 0`, the statistics for each table in the specified database are returned.

`pgpro_stats_vacuum_indexes`(`dboid` `oid`, `relid` `oid`) returns `setof record`

Defines the row of the `pgpro_stats_vacuum_indexes` view, which is described in detail in [Table F.81](#), for the database specified by `dboid` and index specified by `relid`. If `relid = 0`, the statistics for each index in the specified database are returned.

## F.37.7. Configuration Parameters

### F.37.7.1. General Settings

`pgpro_stats.max` (`integer`)

`pgpro_stats.max` is the maximum number of statements tracked by the module (i.e., the maximum number of rows in the `pgpro_stats_statements` view). If more distinct statements than that are

observed, information about the least-executed statements is discarded. The default value is 5000. This parameter can only be set at server start.

`pgpro_stats.max_totals` (integer)

`pgpro_stats.max_totals` is the maximum number of objects tracked by the module (i.e., the maximum number of rows in the `pgpro_stats_totals` view). If more distinct objects than that are observed, information about least-used objects is discarded. The default value is 1000. This parameter can only be set at server start.

`pgpro_stats.track` (enum)

`pgpro_stats.track` controls which statements are counted by the module. Specify `top` to track top-level statements (those issued directly by clients), `all` to also track nested statements (such as statements invoked within functions), or `none` to disable statement statistics collection. The default value is `top`. Only superusers can change this setting.

`pgpro_stats.track_utility` (boolean)

`pgpro_stats.track_utility` controls whether utility commands are tracked by the module. Utility commands are all those other than `SELECT`, `INSERT`, `UPDATE` and `DELETE`. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_planning` (boolean)

`pgpro_stats.track_planning` controls whether planning operations and duration are tracked by the module. Enabling this parameter may incur a noticeable performance penalty, especially when statements with identical query structure are executed by many concurrent connections which compete to update a small number of `pg_stat_statements` entries. The default value is `off`. Only superusers can change this setting.

`pgpro_stats.track_totals` (boolean)

`pgpro_stats.track_totals` controls whether aggregate statistics for objects (cluster, users, databases etc.) are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_cluster` (boolean)

`pgpro_stats.track_cluster` controls whether aggregate statistics for the cluster are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_databases` (boolean)

`pgpro_stats.track_databases` controls whether aggregate statistics for the databases are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_users` (boolean)

`pgpro_stats.track_users` controls whether aggregate statistics for the users are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_applications` (boolean)

`pgpro_stats.track_applications` controls whether aggregate statistics for the applications (whose names are set by [application\\_name](#)) are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_client_addr` (boolean)

`pgpro_stats.track_client_addr` controls whether aggregate statistics for the client IP addresses are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_backends` (boolean)

`pgpro_stats.track_backends` controls whether aggregate statistics for the backends are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_sessions` (boolean)

`pgpro_stats.track_sessions` controls whether aggregate statistics for the sessions are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.save` (boolean)

`pgpro_stats.save` specifies whether to save statement statistics across server shutdowns. If it is `off` then statistics are neither saved at shutdown nor reloaded at server start. The default value is `on`. This parameter can only be set in the `postgresql.conf` file or on the server command line.

`pgpro_stats.plan_format` (text)

`pgpro_stats.plan_format` selects the `EXPLAIN` format for the query plan. Possible values are `text`, `xml`, `json`, and `yaml`. The default value is `text`. Changing this parameter requires a server restart.

`pgpro_stats.enable_profile` (boolean)

`pgpro_stats.enable_profile` enables sampling of wait events for separate statements. The default value is `true`. Changing this parameter requires a server restart.

`pgpro_stats.query_sample_rate` (float)

`pgpro_stats.query_sample_rate` specifies the fraction of queries that are randomly selected for statistics calculation. Possible values lie between `0.0` (no queries) and `1.0` (all queries). The default value is `1.0`. Changing this parameter requires a server restart.

`pgpro_stats.profile_period` (integer)

`pgpro_stats.profile_period` specifies the period, in milliseconds, during which to sample wait events. The default value is `10`. Only superusers can change this setting.

`pgpro_stats.metrics_buffer_size` (integer)

`pgpro_stats.metrics_buffer_size` specifies the size of the ring buffer used for collecting statistical metrics. The default value is `16kB`. Changing this parameter requires a server restart.

`pgpro_stats.metrics_workers` (integer)

`pgpro_stats.metrics_workers` specifies the number of workers used to collect statistical metrics. If this parameter is set to `2` or higher, one of the workers serves as the master worker distributing queries to other workers. If only one worker is available, it gets reloaded to connect to different databases. Setting this parameter to `0` disables metrics collection. The default value is `2`. Changing this parameter requires a server restart.

### F.37.7.2. Metrics Settings

The following parameters can be used to define a custom metric to collect. The `N` placeholder in the parameter name serves as a unique identifier of the metric to which this setting should apply; it must be set to a non-negative integer for each metric.

When you add these parameters for a new metric, you have to restart the server for the changes to take effect. Once the new metric is added, its parameters can be changed without a server restart by simply reloading the `postgresql.conf` configuration file.

`pgpro_stats.metric_N_name` (text)

The name of metric `N`. This name will be displayed in the `metric_name` column of the `pgpro_stats_metrics` view.

`pgpro_stats.metric_N_query` (text)

The query statement that defines the metric to collect.

`pgpro_stats.metric_N_period` (integer)

The time interval at which to collect metric *N*, in milliseconds. Default: 60000 ms

`pgpro_stats.metric_N_db` (text)

The list of databases for which to collect metric *N*. Database names must be separated by commas. You can specify the `*` character to select all databases in the cluster except the template databases. If you need to analyze the template databases as well, you have to specify them explicitly.

`pgpro_stats.metric_N_user` (text)

The name of the user on behalf of which to collect metric *N*. This user must have access to the database for which the metric is collected.

## F.37.8. Authors

Postgres Professional, Moscow, Russia

## F.38. `pg_query_state`

The `pg_query_state` module provides facility to know the current state of query execution on working backend.

### F.38.1. Overview

Each non-utility query statement (SELECT/INSERT/UPDATE/DELETE) after optimization/planning stage is translated into plan tree, which is kind of imperative representation of declarative SQL query. EXPLAIN ANALYZE request allows to demonstrate execution statistics gathered from each node of plan tree (full time of execution, number of rows emitted to upper nodes, etc). But this statistics is collected after execution of query. This module allows to show actual statistics of query running on external backend. At that, format of resulting output is almost identical to ordinal EXPLAIN ANALYZE. Thus users are able to track of query execution in progress. In fact, this module is able to explore external backend and determine its actual state. Particularly it's helpful when backend executes a heavy query or gets stuck.

### F.38.2. Use cases

Using this module there can help in the following things:

- detect a long query (along with other monitoring tools);
- supervise query execution.

### F.38.3. Installation

To install `pg_query_state` run in `psql`:

```
CREATE EXTENSION pg_query_state;
```

Then modify `shared_preload_libraries` parameter in `postgres.conf` as following:

```
shared_preload_libraries = 'pg_query_state'
```

It will require to restart the Postgres Pro instance.

### F.38.4. Function `pg_query_state`

```
pg_query_state(integer pid,  
               verbose boolean DEFAULT FALSE,  
               costs   boolean DEFAULT FALSE,
```

```

        timing    boolean DEFAULT FALSE,
        buffers   boolean DEFAULT FALSE,
        triggers  boolean DEFAULT FALSE,
        format    text     DEFAULT 'text')
returns TABLE (pid integer,
                frame_number integer,
                query_text text,
                plan text,
                leader_pid integer)

```

Extract current query state from backend with specified `pid`. Since parallel query can spawn multiple workers and function call causes nested subqueries so that state of execution may be viewed as stack of running queries, return value of `pg_query_state` has type `TABLE (pid integer, frame_number integer, query_text text, plan text, leader_pid integer)`. It represents tree structure consisting of leader process and its spawned workers identified by `pid`. Each worker refers to leader through `leader_pid` column. For leader process the value of this column is `null`. The state of each process is represented as stack of function calls. Each frame of that stack is specified as correspondence between `frame_number` starting from zero, `query_text` and `plan` with online statistics columns.

Thus, user can see the states of main query and queries generated from function calls for leader process and all workers spawned from it.

In process of execution some nodes of plan tree can take loops of full execution. Therefore statistics for each node consists of two parts: average statistics for previous loops just like in `EXPLAIN ANALYZE` output and statistics for current loop if node have not finished.

Optional arguments:

- `verbose` - use `EXPLAIN VERBOSE` for plan printing;
- `costs` - costs for each node;
- `timing` - print timing data for each node, if collecting of timing statistics is turned off on called side resulting output will contain `WARNING` message `timing statistics disabled`;
- `buffers` - print buffers usage, if collecting of buffers statistics is turned off on called side resulting output will contain `WARNING` message `buffers statistics disabled`;
- `triggers` - include triggers statistics in result plan trees;
- `format` - `EXPLAIN` format to be used for plans printing, possible values: `text`, `xml`, `json`, `yaml`.

If callable backend is not executing any query the function prints `INFO` message about backend's state taken from `pg_stat_activity` view if it exists there.

Calling role have to be superuser or member of the role whose backend is being called. Otherwise function prints `ERROR` message `permission denied`.

### F.38.5. Configuration settings

There are several user-accessible GUC variables designed to toggle the whole module and the collecting of specific statistic parameters while query is running:

- `pg_query_state.enable` - disable (or enable) `pg_query_state` completely, default value is `true`
- `pg_query_state.enable_timing` - collect timing data for each node, default value is `false`
- `pg_query_state.enable_buffers` - collect buffers usage, default value is `false`

These parameters are set on called side before running any queries whose states are attempted to extract. `WARNING`: if `pg_query_state.enable_timing` is turned off the calling side cannot get time statistics, similarly for `pg_query_state.enable_buffers` parameter.

### F.38.6. Examples

Set maximum number of parallel workers on `gather` node equals 2:

```
postgres=# set max_parallel_workers_per_gather = 2;
```

Assume one backend with pid = 49265 performs a simple query:

```
postgres=# select pg_backend_pid();
pg_backend_pid
-----
    49265
(1 row)
postgres=# select count(*) from foo join bar on foo.c1=bar.c1;
```

Other backend can extract intermediate state of execution that query:

```
postgres=# \x
postgres=# select * from pg_query_state(49265);
-[ RECORD
  1 ]+-----
pid          | 49265
frame_number | 0
query_text   | select count(*) from foo join bar on foo.c1=bar.c1;
plan         | Finalize Aggregate (Current loop: actual rows=0, loop number=1)
              |
              |   -> Gather (Current loop: actual rows=0, loop number=1)
              |
              |     Workers Planned: 2
              |
              |     Workers Launched: 2
              |
              |   -> Partial Aggregate (Current loop: actual rows=0, loop
number=1)
              |
              |     -> Nested Loop (Current loop: actual rows=12, loop
number=1)
              |
              |       Join Filter: (foo.c1 = bar.c1)
              |
              |       Rows Removed by Join Filter: 5673232
              |
              |     -> Parallel Seq Scan on foo (Current loop: actual
rows=12, loop number=1)
              |
              |       -> Seq Scan on bar (actual rows=500000 loops=11)
              |       (Current loop: actual rows=173244, loop number=12)
leader_pid   | (null)
-[ RECORD
  2 ]+-----
pid          | 49324
frame_number | 0
query_text   | <parallel query>

              |
              |     Rows Removed by Join Filter: 4896779
              |
              |   -> Parallel Seq Scan on foo (Current loop: actual rows=10, loop
number=1)
              |
              |     -> Seq Scan on bar (actual rows=500000 loops=9) (Current loop:
actual rows=396789, loop number=10)
leader_pid   | 49265
```

```

-[ RECORD
 3 ]+-----
pid          | 49323
frame_number | 0
query_text   | <parallel query>
plan         | Partial Aggregate (Current loop: actual rows=0, loop number=1)
              |
              |   -> Nested Loop (Current loop: actual rows=11, loop number=1)
              |   |
              |   |   Join Filter: (foo.c1 = bar.c1)
              |   |   |
              |   |   |   Rows Removed by Join Filter: 5268783
              |   |   |   |
              |   |   |   |   -> Parallel Seq Scan on foo (Current loop: actual rows=11, loop
              |   |   |   |   |   number=1)
              |   |   |   |   |
              |   |   |   |   |   -> Seq Scan on bar (actual rows=500000 loops=10) (Current loop:
              |   |   |   |   |   |   actual rows=268794, loop number=11)
leader_pid   | 49265

```

In example above working backend spawns two parallel workers with pids 49324 and 49323. Their leader\_pid column's values clarify that these workers belong to the main backend. Seq Scan node has statistics on passed loops (average number of rows delivered to Nested Loop and number of passed loops are shown) and statistics on current loop. Other nodes has statistics only for current loop as this loop is first (loop number = 1).

Assume first backend executes some function:

```
postgres=# select n_join_foo_bar();
```

Other backend can get the follow output:

```

postgres=# select * from pg_query_state(49265);
-[ RECORD
 1 ]+-----
pid          | 49265
frame_number | 0
query_text   | select n_join_foo_bar();
plan         | Result (Current loop: actual rows=0, loop number=1)
leader_pid   | (null)
-[ RECORD
 2 ]+-----
pid          | 49265
frame_number | 1
query_text   | SELECT (select count(*) from foo join bar on foo.c1=bar.c1)
plan         | Result (Current loop: actual rows=0, loop number=1)
              |
              |   InitPlan 1 (returns $0)
              |   |
              |   |   -> Aggregate (Current loop: actual rows=0, loop number=1)
              |   |   |
              |   |   |   -> Nested Loop (Current loop: actual rows=51, loop number=1)
              |   |   |   |
              |   |   |   |   Join Filter: (foo.c1 = bar.c1)
              |   |   |   |   |
              |   |   |   |   |   Rows Removed by Join Filter: 51636304
              |   |   |   |   |   |
              |   |   |   |   |   |   -> Seq Scan on bar (Current loop: actual rows=52, loop
              |   |   |   |   |   |   |   number=1)

```

## Additional Supplied Modules

---

```
          |          -> Materialize (actual rows=1000000 loops=51) (Current
loop: actual rows=636355, loop number=52)+
          |          -> Seq Scan on foo (Current loop: actual
rows=1000000, loop number=1)
leader_pid | (null)
```

First row corresponds to function call, second - to query which is in the body of that function.

We can get result plans in different format (e.g. json):

```
postgres=# select * from pg_query_state(pid := 49265, format := 'json');
-[ RECORD 1 ]+-----+
pid          | 49265
frame_number | 0
query_text   | select * from n_join_foo_bar();
plan         | {
              |   "Plan": {
              |     "Node Type": "Function Scan",
              |     "Parallel Aware": false,
              |     "Function Name": "n_join_foo_bar",
              |     "Alias": "n_join_foo_bar",
              |     "Current loop": {
              |       "Actual Loop Number": 1,
              |       "Actual Rows": 0
              |     }
              |   }
              | }
leader_pid   | (null)
-[ RECORD 2 ]+-----+
pid          | 49265
frame_number | 1
query_text   | SELECT (select count(*) from foo join bar on foo.c1=bar.c1)
plan         | {
              |   "Plan": {
              |     "Node Type": "Result",
              |     "Parallel Aware": false,
              |     "Current loop": {
              |       "Actual Loop Number": 1,
              |       "Actual Rows": 0
              |     },
              |   "Plans": [
              |     {
              |       "Node Type": "Aggregate",
              |       "Strategy": "Plain",
              |       "Partial Mode": "Simple",
              |       "Parent Relationship": "InitPlan",
              |       "Subplan Name": "InitPlan 1 (returns $0)",
              |       "Parallel Aware": false,
              |       "Current loop": {
              |         "Actual Loop Number": 1,
              |         "Actual Rows": 0
              |       },
              |     },
              |     {
              |       "Node Type": "Nested Loop",
              |       "Parent Relationship": "Outer",
              |       "Parallel Aware": false,
              |       "Join Type": "Inner",
```

## F.39.1. Overview

`pgrowlocks(text)` returns setof record

The parameter is the name of a table. The result is a set of records, with one row for each locked row within the table. The output columns are shown in [Table F.84](#).

**Table F.84. pgrowlocks Output Columns**

Name	Type	Description
<code>locked_row</code>	<code>tid</code>	Tuple ID (TID) of locked row
<code>locker</code>	<code>xid</code>	Transaction ID of locker, or multixact ID if multitransaction
<code>multi</code>	<code>boolean</code>	True if locker is a multitransaction
<code>xids</code>	<code>xid[]</code>	Transaction IDs of lockers (more than one if multitransaction)
<code>modes</code>	<code>text[]</code>	Lock mode of lockers (more than one if multitransaction), an array of Key Share, Share, For No Key Update, No Key Update, For Update, Update.
<code>pids</code>	<code>integer[]</code>	Process IDs of locking backends (more than one if multitransaction)

`pgrowlocks` takes `AccessShareLock` for the target table and reads each row one by one to collect the row locking information. This is not very speedy for a large table. Note that:

1. If an `ACCESS EXCLUSIVE` lock is taken on the table, `pgrowlocks` will be blocked.
2. `pgrowlocks` is not guaranteed to produce a self-consistent snapshot. It is possible that a new row lock is taken, or an old lock is freed, during its execution.

`pgrowlocks` does not show the contents of locked rows. If you want to take a look at the row contents at the same time, you could do something like this:

```
SELECT * FROM accounts AS a, pgrowlocks('accounts') AS p
WHERE p.locked_row = a.ctid;
```

Be aware however that such a query will be very inefficient.

## F.39.2. Sample Output

```
=# SELECT * FROM pgrowlocks('t1');
locked_row | locker | multi | xids | modes | pids
-----+-----+-----+-----+-----+-----
(0,1)      | 609   | f     | {609} | {"For Share"} | {3161}
(0,2)      | 609   | f     | {609} | {"For Share"} | {3161}
(0,3)      | 607   | f     | {607} | {"For Update"} | {3107}
(0,4)      | 607   | f     | {607} | {"For Update"} | {3107}
(4 rows)
```

## F.40. pg\_stat\_statements

The `pg_stat_statements` module provides a means for tracking planning and execution statistics of all SQL statements executed by a server.

The module must be loaded by adding `pg_stat_statements` to `shared_preload_libraries` in `postgresql.conf`, because it requires additional shared memory. This means that a server restart is needed to add or remove the module.

When `pg_stat_statements` is loaded, it tracks statistics across all databases of the server. To access and manipulate these statistics, the module provides a view, `pg_stat_statements`, and the utility functions `pg_stat_statements_reset` and `pg_stat_statements`. These are not available globally but can be enabled for a specific database with `CREATE EXTENSION pg_stat_statements`.

### F.40.1. The `pg_stat_statements` View

The statistics gathered by the module are made available via a view named `pg_stat_statements`. This view contains one row for each distinct database ID, user ID and query ID (up to the maximum number of distinct statements that the module can track). The columns of the view are shown in [Table F.85](#).

**Table F.85. `pg_stat_statements` Columns**

Column Type	Description
<code>userid oid</code> (references <code>pg_authid .oid</code> )	OID of user who executed the statement
<code>dbid oid</code> (references <code>pg_database .oid</code> )	OID of database in which the statement was executed
<code>queryid bigint</code>	Internal hash code, computed from the statement's parse tree
<code>query text</code>	Text of a representative statement
<code>plans bigint</code>	Number of times the statement was planned (if <code>pg_stat_statements.track_planning</code> is enabled, otherwise zero)
<code>total_plan_time double precision</code>	Total time spent planning the statement, in milliseconds (if <code>pg_stat_statements.track_planning</code> is enabled, otherwise zero)
<code>min_plan_time double precision</code>	Minimum time spent planning the statement, in milliseconds (if <code>pg_stat_statements.track_planning</code> is enabled, otherwise zero)
<code>max_plan_time double precision</code>	Maximum time spent planning the statement, in milliseconds (if <code>pg_stat_statements.track_planning</code> is enabled, otherwise zero)
<code>mean_plan_time double precision</code>	Mean time spent planning the statement, in milliseconds (if <code>pg_stat_statements.track_planning</code> is enabled, otherwise zero)
<code>stddev_plan_time double precision</code>	Population standard deviation of time spent planning the statement, in milliseconds (if <code>pg_stat_statements.track_planning</code> is enabled, otherwise zero)
<code>calls bigint</code>	Number of times the statement was executed
<code>total_exec_time double precision</code>	Total time spent executing the statement, in milliseconds
<code>min_exec_time double precision</code>	

<b>Column Type</b>	<b>Description</b>
	Minimum time spent executing the statement, in milliseconds
max_exec_time double precision	Maximum time spent executing the statement, in milliseconds
mean_exec_time double precision	Mean time spent executing the statement, in milliseconds
stddev_exec_time double precision	Population standard deviation of time spent executing the statement, in milliseconds
rows bigint	Total number of rows retrieved or affected by the statement
shared_blks_hit bigint	Total number of shared block cache hits by the statement
shared_blks_read bigint	Total number of shared blocks read by the statement
shared_blks_dirtied bigint	Total number of shared blocks dirtied by the statement
shared_blks_written bigint	Total number of shared blocks written by the statement
local_blks_hit bigint	Total number of local block cache hits by the statement
local_blks_read bigint	Total number of local blocks read by the statement
local_blks_dirtied bigint	Total number of local blocks dirtied by the statement
local_blks_written bigint	Total number of local blocks written by the statement
temp_blks_read bigint	Total number of temp blocks read by the statement
temp_blks_written bigint	Total number of temp blocks written by the statement
blk_read_time double precision	Total time the statement spent reading blocks, in milliseconds (if <a href="#">track_io_timing</a> is enabled, otherwise zero)
blk_write_time double precision	Total time the statement spent writing blocks, in milliseconds (if <a href="#">track_io_timing</a> is enabled, otherwise zero)
wal_records bigint	Total number of WAL records generated by the statement
wal_fpi bigint	Total number of WAL full page images generated by the statement
wal_bytes numeric	Total amount of WAL generated by the statement in bytes

For security reasons, only superusers and members of the `pg_read_all_stats` role are allowed to see the SQL text and `queryid` of queries executed by other users. Other users can see the statistics, however, if the view has been installed in their database.

Plannable queries (that is, `SELECT`, `INSERT`, `UPDATE`, and `DELETE`) are combined into a single `pg_stat_statements` entry whenever they have identical query structures according to an internal hash

calculation. Typically, two queries will be considered the same for this purpose if they are semantically equivalent except for the values of literal constants appearing in the query. Utility commands (that is, all other commands) are compared strictly on the basis of their textual query strings, however.

When a constant's value has been ignored for purposes of matching the query to other queries, the constant is replaced by a parameter symbol, such as `$1`, in the `pg_stat_statements` display. The rest of the query text is that of the first query that had the particular `queryid` hash value associated with the `pg_stat_statements` entry.

In some cases, queries with visibly different texts might get merged into a single `pg_stat_statements` entry. Normally this will happen only for semantically equivalent queries, but there is a small chance of hash collisions causing unrelated queries to be merged into one entry. (This cannot happen for queries belonging to different users or databases, however.)

Since the `queryid` hash value is computed on the post-parse-analysis representation of the queries, the opposite is also possible: queries with identical texts might appear as separate entries, if they have different meanings as a result of factors such as different `search_path` settings.

Consumers of `pg_stat_statements` may wish to use `queryid` (perhaps in combination with `dbid` and `userid`) as a more stable and reliable identifier for each entry than its query text. However, it is important to understand that there are only limited guarantees around the stability of the `queryid` hash value. Since the identifier is derived from the post-parse-analysis tree, its value is a function of, among other things, the internal object identifiers appearing in this representation. This has some counterintuitive implications. For example, `pg_stat_statements` will consider two apparently-identical queries to be distinct, if they reference a table that was dropped and recreated between the executions of the two queries. The hashing process is also sensitive to differences in machine architecture and other facets of the platform. Furthermore, it is not safe to assume that `queryid` will be stable across major versions of Postgres Pro.

As a rule of thumb, `queryid` values can be assumed to be stable and comparable only so long as the underlying server version and catalog metadata details stay exactly the same. Two servers participating in replication based on physical WAL replay can be expected to have identical `queryid` values for the same query. However, logical replication schemes do not promise to keep replicas identical in all relevant details, so `queryid` will not be a useful identifier for accumulating costs across a set of logical replicas. If in doubt, direct testing is recommended.

The parameter symbols used to replace constants in representative query texts start from the next number after the highest `$n` parameter in the original query text, or `$1` if there was none. It's worth noting that in some cases there may be hidden parameter symbols that affect this numbering. For example, PL/pgSQL uses hidden parameter symbols to insert values of function local variables into queries, so that a PL/pgSQL statement like `SELECT i + 1 INTO j` would have representative text like `SELECT i + $2`.

The representative query texts are kept in an external disk file, and do not consume shared memory. Therefore, even very lengthy query texts can be stored successfully. However, if many long query texts are accumulated, the external file might grow unmanageably large. As a recovery method if that happens, `pg_stat_statements` may choose to discard the query texts, whereupon all existing entries in the `pg_stat_statements` view will show null `query` fields, though the statistics associated with each `queryid` are preserved. If this happens, consider reducing `pg_stat_statements.max` to prevent recurrences.

`plans` and `calls` aren't always expected to match because planning and execution statistics are updated at their respective end phase, and only for successful operations. For example, if a statement is successfully planned but fails during the execution phase, only its planning statistics will be updated. If planning is skipped because a cached plan is used, only its execution statistics will be updated.

## F.40.2. Functions

`pg_stat_statements_reset`(`userid` Oid, `dbid` Oid, `queryid` bigint) returns void

`pg_stat_statements_reset` discards statistics gathered so far by `pg_stat_statements` corresponding to the specified `userid`, `dbid` and `queryid`. If any of the parameters are not specified,

the default value 0 (invalid) is used for each of them and the statistics that match with other parameters will be reset. If no parameter is specified or all the specified parameters are 0 (invalid), it will discard all statistics. By default, this function can only be executed by superusers. Access may be granted to others using `GRANT`.

`pg_stat_statements(showtext boolean)` returns setof record

The `pg_stat_statements` view is defined in terms of a function also named `pg_stat_statements`. It is possible for clients to call the `pg_stat_statements` function directly, and by specifying `showtext := false` have query text be omitted (that is, the `OUT` argument that corresponds to the view's query column will return nulls). This feature is intended to support external tools that might wish to avoid the overhead of repeatedly retrieving query texts of indeterminate length. Such tools can instead cache the first query text observed for each entry themselves, since that is all `pg_stat_statements` itself does, and then retrieve query texts only as needed. Since the server stores query texts in a file, this approach may reduce physical I/O for repeated examination of the `pg_stat_statements` data.

### F.40.3. Configuration Parameters

`pg_stat_statements.max (integer)`

`pg_stat_statements.max` is the maximum number of statements tracked by the module (i.e., the maximum number of rows in the `pg_stat_statements` view). If more distinct statements than that are observed, information about the least-executed statements is discarded. The default value is 5000. This parameter can only be set at server start.

`pg_stat_statements.track (enum)`

`pg_stat_statements.track` controls which statements are counted by the module. Specify `top` to track top-level statements (those issued directly by clients), `all` to also track nested statements (such as statements invoked within functions), or `none` to disable statement statistics collection. The default value is `top`. Only superusers can change this setting.

`pg_stat_statements.track_utility (boolean)`

`pg_stat_statements.track_utility` controls whether utility commands are tracked by the module. Utility commands are all those other than `SELECT`, `INSERT`, `UPDATE` and `DELETE`. The default value is `on`. Only superusers can change this setting.

`pg_stat_statements.track_planning (boolean)`

`pg_stat_statements.track_planning` controls whether planning operations and duration are tracked by the module. Enabling this parameter may incur a noticeable performance penalty, especially when statements with identical query structure are executed by many concurrent connections which compete to update a small number of `pg_stat_statements` entries. The default value is `off`. Only superusers can change this setting.

`pg_stat_statements.save (boolean)`

`pg_stat_statements.save` specifies whether to save statement statistics across server shutdowns. If it is `off` then statistics are not saved at shutdown nor reloaded at server start. The default value is `on`. This parameter can only be set in the `postgresql.conf` file or on the server command line.

The module requires additional shared memory proportional to `pg_stat_statements.max`. Note that this memory is consumed whenever the module is loaded, even if `pg_stat_statements.track` is set to `none`.

These parameters must be set in `postgresql.conf`. Typical usage might be:

```
# postgresql.conf
shared_preload_libraries = 'pg_stat_statements'

pg_stat_statements.max = 10000
```

```
pg_stat_statements.track = all
```

## F.40.4. Sample Output

```
bench=# SELECT pg_stat_statements_reset();

## F.40.5. Authors

Takahiro Itagaki <itagaki.takahiro@oss.ntt.co.jp>. Query normalization added by Peter Geoghegan <peter@2ndquadrant.com>.

## F.41. pgstattuple

The `pgstattuple` module provides various functions to obtain tuple-level statistics.

Because these functions return detailed page-level information, access is restricted by default. By default, only the role `pg_stat_scan_tables` has `EXECUTE` privilege. Superusers of course bypass this restriction. After the extension has been installed, users may issue `GRANT` commands to change the privileges on the functions to allow others to execute them. However, it might be preferable to add those users to the `pg_stat_scan_tables` role instead.

### F.41.1. Functions

`pgstattuple(regclass)` returns record

`pgstattuple` returns a relation's physical length, percentage of “dead” tuples, and other info. This may help users to determine whether vacuum is necessary or not. The argument is the target relation's name (optionally schema-qualified) or OID. For example:

```
test=> SELECT * FROM pgstattuple('pg_catalog.pg_proc');
-[ RECORD 1 ]-----+-----
table_len      | 458752
tuple_count    | 1470
tuple_len      | 438896
tuple_percent  | 95.67
dead_tuple_count | 11
dead_tuple_len | 3157
dead_tuple_percent | 0.69
free_space     | 8932
free_percent   | 1.95
```

The output columns are described in [Table F.86](#).

**Table F.86.** `pgstattuple` Output Columns

Column	Type	Description
<code>table_len</code>	<code>bigint</code>	Physical relation length in bytes
<code>tuple_count</code>	<code>bigint</code>	Number of live tuples
<code>tuple_len</code>	<code>bigint</code>	Total length of live tuples in bytes
<code>tuple_percent</code>	<code>float8</code>	Percentage of live tuples
<code>dead_tuple_count</code>	<code>bigint</code>	Number of dead tuples
<code>dead_tuple_len</code>	<code>bigint</code>	Total length of dead tuples in bytes
<code>dead_tuple_percent</code>	<code>float8</code>	Percentage of dead tuples
<code>free_space</code>	<code>bigint</code>	Total free space in bytes
<code>free_percent</code>	<code>float8</code>	Percentage of free space

#### Note

The `table_len` will always be greater than the sum of the `tuple_len`, `dead_tuple_len` and `free_space`. The difference is accounted for by fixed page overhead, the per-page table of pointers to tuples, and padding to ensure that tuples are correctly aligned.

`pgstattuple` acquires only a read lock on the relation. So the results do not reflect an instantaneous snapshot; concurrent updates will affect them.

`pgstattuple` judges a tuple is “dead” if `HeapTupleSatisfiesDirty` returns false.

`pgstattuple(text)` returns record

This is the same as `pgstattuple(regclass)`, except that the target relation is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

`pgstatindex(regclass)` returns record

`pgstatindex` returns a record showing information about a B-tree index. For example:

```
test=> SELECT * FROM pgstatindex('pg_cast_oid_index');
-[ RECORD 1 ]-----+-----
version          | 2
tree_level       | 0
index_size       | 16384
root_block_no    | 1
internal_pages   | 0
leaf_pages       | 1
empty_pages      | 0
deleted_pages    | 0
avg_leaf_density | 54.27
leaf_fragmentation | 0
```

The output columns are:

Column	Type	Description
version	integer	B-tree version number
tree_level	integer	Tree level of the root page
index_size	bigint	Total index size in bytes
root_block_no	bigint	Location of root page (zero if none)
internal_pages	bigint	Number of “internal” (upper-level) pages
leaf_pages	bigint	Number of leaf pages
empty_pages	bigint	Number of empty pages
deleted_pages	bigint	Number of deleted pages
avg_leaf_density	float8	Average density of leaf pages
leaf_fragmentation	float8	Leaf page fragmentation

The reported `index_size` will normally correspond to one more page than is accounted for by `internal_pages + leaf_pages + empty_pages + deleted_pages`, because it also includes the index's metapage.

As with `pgstattuple`, the results are accumulated page-by-page, and should not be expected to represent an instantaneous snapshot of the whole index.

`pgstatindex(text)` returns record

This is the same as `pgstatindex(regclass)`, except that the target index is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

`pgstatginindex(regclass)` returns record

`pgstatginindex` returns a record showing information about a GIN index. For example:

```
test=> SELECT * FROM pgstatginindex('test_gin_index');
-[ RECORD 1 ]--+-
version          | 1
```

```
pending_pages | 0
pending_tuples | 0
```

The output columns are:

Column	Type	Description
version	integer	GIN version number
pending_pages	integer	Number of pages in the pending list
pending_tuples	bigint	Number of tuples in the pending list

`pgstathashindex(regclass)` returns record

`pgstathashindex` returns a record showing information about a HASH index. For example:

```
test=> select * from pgstathashindex('con_hash_index');
-[ RECORD 1 ]--+-+-----
version          | 4
bucket_pages    | 33081
overflow_pages  | 0
bitmap_pages    | 1
unused_pages    | 32455
live_items      | 10204006
dead_items      | 0
free_percent    | 61.8005949100872
```

The output columns are:

Column	Type	Description
version	integer	HASH version number
bucket_pages	bigint	Number of bucket pages
overflow_pages	bigint	Number of overflow pages
bitmap_pages	bigint	Number of bitmap pages
unused_pages	bigint	Number of unused pages
live_items	bigint	Number of live tuples
dead_tuples	bigint	Number of dead tuples
free_percent	float	Percentage of free space

`pg_relpages(regclass)` returns bigint

`pg_relpages` returns the number of pages in the relation.

`pg_relpages(text)` returns bigint

This is the same as `pg_relpages(regclass)`, except that the target relation is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

`pgstattuple_approx(regclass)` returns record

`pgstattuple_approx` is a faster alternative to `pgstattuple` that returns approximate results. The argument is the target relation's name or OID. For example:

```
test=> SELECT * FROM pgstattuple_approx('pg_catalog.pg_proc'::regclass);
-[ RECORD 1 ]-----+-----
table_len          | 573440
scanned_percent    | 2
```

```

approx_tuple_count | 2740
approx_tuple_len   | 561210
approx_tuple_percent | 97.87
dead_tuple_count   | 0
dead_tuple_len     | 0
dead_tuple_percent | 0
approx_free_space  | 11996
approx_free_percent | 2.09

```

The output columns are described in [Table F.87](#).

Whereas `pgstattuple` always performs a full-table scan and returns an exact count of live and dead tuples (and their sizes) and free space, `pgstattuple_approx` tries to avoid the full-table scan and returns exact dead tuple statistics along with an approximation of the number and size of live tuples and free space.

It does this by skipping pages that have only visible tuples according to the visibility map (if a page has the corresponding VM bit set, then it is assumed to contain no dead tuples). For such pages, it derives the free space value from the free space map, and assumes that the rest of the space on the page is taken up by live tuples.

For pages that cannot be skipped, it scans each tuple, recording its presence and size in the appropriate counters, and adding up the free space on the page. At the end, it estimates the total number of live tuples based on the number of pages and tuples scanned (in the same way that `VACUUM` estimates `pg_class.reltuples`).

**Table F.87. `pgstattuple_approx` Output Columns**

Column	Type	Description
<code>table_len</code>	<code>bigint</code>	Physical relation length in bytes (exact)
<code>scanned_percent</code>	<code>float8</code>	Percentage of table scanned
<code>approx_tuple_count</code>	<code>bigint</code>	Number of live tuples (estimated)
<code>approx_tuple_len</code>	<code>bigint</code>	Total length of live tuples in bytes (estimated)
<code>approx_tuple_percent</code>	<code>float8</code>	Percentage of live tuples
<code>dead_tuple_count</code>	<code>bigint</code>	Number of dead tuples (exact)
<code>dead_tuple_len</code>	<code>bigint</code>	Total length of dead tuples in bytes (exact)
<code>dead_tuple_percent</code>	<code>float8</code>	Percentage of dead tuples
<code>approx_free_space</code>	<code>bigint</code>	Total free space in bytes (estimated)
<code>approx_free_percent</code>	<code>float8</code>	Percentage of free space

In the above output, the free space figures may not match the `pgstattuple` output exactly, because the free space map gives us an exact figure, but is not guaranteed to be accurate to the byte.

## F.41.2. Authors

Tatsuo Ishii, Satoshi Nagayasu and Abhijit Menon-Sen

## F.42. `pg_trgm`

The `pg_trgm` module provides functions and operators for determining the similarity of alphanumeric text based on trigram matching, as well as index operator classes that support fast searching for similar strings.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.42.1. Trigram (or Trigraph) Concepts

A trigram is a group of three consecutive characters taken from a string. We can measure the similarity of two strings by counting the number of trigrams they share. This simple idea turns out to be very effective for measuring the similarity of words in many natural languages.

#### Note

`pg_trgm` ignores non-word characters (non-alphanumerics) when extracting trigrams from a string. Each word is considered to have two spaces prefixed and one space suffixed when determining the set of trigrams contained in the string. For example, the set of trigrams in the string “cat” is “ c”, “ ca”, “cat”, and “at ”. The set of trigrams in the string “foo|bar” is “ f”, “ fo”, “foo”, “oo ”, “ b”, “ ba”, “bar”, and “ar ”.

### F.42.2. Functions and Operators

The functions provided by the `pg_trgm` module are shown in [Table F.88](#), the operators in [Table F.89](#).

**Table F.88.** `pg_trgm` Functions

Function	Description
<code>similarity ( text, text ) → real</code>	Returns a number that indicates how similar the two arguments are. The range of the result is zero (indicating that the two strings are completely dissimilar) to one (indicating that the two strings are identical).
<code>show_trgm ( text ) → text []</code>	Returns an array of all the trigrams in the given string. (In practice this is seldom useful except for debugging.)
<code>word_similarity ( text, text ) → real</code>	Returns a number that indicates the greatest similarity between the set of trigrams in the first string and any continuous extent of an ordered set of trigrams in the second string. For details, see the explanation below.
<code>strict_word_similarity ( text, text ) → real</code>	Same as <code>word_similarity</code> , but forces extent boundaries to match word boundaries. Since we don't have cross-word trigrams, this function actually returns greatest similarity between first string and any continuous extent of words of the second string.
<code>show_limit () → real</code>	Returns the current similarity threshold used by the <code>%</code> operator. This sets the minimum similarity between two words for them to be considered similar enough to be misspellings of each other, for example. ( <i>Deprecated</i> ; instead use <code>SHOW pg_trgm.similarity_threshold</code> .)
<code>set_limit ( real ) → real</code>	Sets the current similarity threshold that is used by the <code>%</code> operator. The threshold must be between 0 and 1 (default is 0.3). Returns the same value passed in. ( <i>Deprecated</i> ; instead use <code>SET pg_trgm.similarity_threshold</code> .)

Consider the following example:

```
# SELECT word_similarity('word', 'two words');
word_similarity
-----
```

0.8

(1 row)

In the first string, the set of trigrams is {" w", " wo", "wor", "ord", "rd "}. In the second string, the ordered set of trigrams is {" t", " tw", "two", "wo ", " w", " wo", "wor", "ord", "rds", "ds "}. The most similar extent of an ordered set of trigrams in the second string is {" w", " wo", "wor", "ord"}, and the similarity is 0.8.

This function returns a value that can be approximately understood as the greatest similarity between the first string and any substring of the second string. However, this function does not add padding to the boundaries of the extent. Thus, the number of additional characters present in the second string is not considered, except for the mismatched word boundaries.

At the same time, `strict_word_similarity` selects an extent of words in the second string. In the example above, `strict_word_similarity` would select the extent of a single word 'words', whose set of trigrams is {" w", " wo", "wor", "ord", "rds", "ds "}.

```
# SELECT strict_word_similarity('word', 'two words'), similarity('word', 'words');
strict_word_similarity | similarity
-----+-----
0.571429 | 0.571429
```

(1 row)

Thus, the `strict_word_similarity` function is useful for finding the similarity to whole words, while `word_similarity` is more suitable for finding the similarity for parts of words.

**Table F.89. pg\_trgm Operators**

Operator	Description
<code>text % text</code>	<code>→ boolean</code> Returns <code>true</code> if its arguments have a similarity that is greater than the current similarity threshold set by <code>pg_trgm.similarity_threshold</code> .
<code>text &lt;% text</code>	<code>→ boolean</code> Returns <code>true</code> if the similarity between the trigram set in the first argument and a continuous extent of an ordered trigram set in the second argument is greater than the current word similarity threshold set by <code>pg_trgm.word_similarity_threshold</code> parameter.
<code>text %&gt; text</code>	<code>→ boolean</code> Commutator of the <code>&lt;%</code> operator.
<code>text &lt;&lt;% text</code>	<code>→ boolean</code> Returns <code>true</code> if its second argument has a continuous extent of an ordered trigram set that matches word boundaries, and its similarity to the trigram set of the first argument is greater than the current strict word similarity threshold set by the <code>pg_trgm.strict_word_similarity_threshold</code> parameter.
<code>text %&gt;&gt; text</code>	<code>→ boolean</code> Commutator of the <code>&lt;&lt;%</code> operator.
<code>text &lt;-&gt; text</code>	<code>→ real</code> Returns the “distance” between the arguments, that is one minus the <code>similarity()</code> value.
<code>text &lt;&lt;-&gt; text</code>	<code>→ real</code> Returns the “distance” between the arguments, that is one minus the <code>word_similarity()</code> value.
<code>text &lt;-&gt;&gt; text</code>	<code>→ real</code> Commutator of the <code>&lt;&lt;-&gt;</code> operator.
<code>text &lt;&lt;&lt;-&gt; text</code>	<code>→ real</code>

Operator	Description
	Returns the “distance” between the arguments, that is one minus the <code>strict_word_similarity()</code> value.
<code>text &lt;-&gt;&gt;&gt; text → real</code>	Commutator of the <<<-> operator.

### F.42.3. GUC Parameters

`pg_trgm.similarity_threshold` (real)

Sets the current similarity threshold that is used by the `%` operator. The threshold must be between 0 and 1 (default is 0.3).

`pg_trgm.word_similarity_threshold` (real)

Sets the current word similarity threshold that is used by the `<%` and `%>` operators. The threshold must be between 0 and 1 (default is 0.6).

`pg_trgm.strict_word_similarity_threshold` (real)

Sets the current strict word similarity threshold that is used by the `<<%` and `%>>` operators. The threshold must be between 0 and 1 (default is 0.5).

### F.42.4. Index Support

The `pg_trgm` module provides GiST and GIN index operator classes that allow you to create an index over a text column for the purpose of very fast similarity searches. These index types support the above-described similarity operators, and additionally support trigram-based index searches for `LIKE`, `ILIKE`, `~` and `~*` queries. (These indexes do not support equality nor simple comparison operators, so you may need a regular B-tree index too.)

Example:

```
CREATE TABLE test_trgm (t text);
CREATE INDEX trgm_idx ON test_trgm USING GIST (t gist_trgm_ops);
```

or

```
CREATE INDEX trgm_idx ON test_trgm USING GIN (t gin_trgm_ops);
```

`gist_trgm_ops` GiST opclass approximates a set of trigrams as a bitmap signature. Its optional integer parameter `siglen` determines the signature length in bytes. The default length is 12 bytes. Valid values of signature length are between 1 and 2024 bytes. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

Example of creating such an index with a signature length of 32 bytes:

```
CREATE INDEX trgm_idx ON test_trgm USING GIST (t gist_trgm_ops(siglen=32));
```

At this point, you will have an index on the `t` column that you can use for similarity searching. A typical query is

```
SELECT t, similarity(t, 'word') AS sml
FROM test_trgm
WHERE t % 'word'
ORDER BY sml DESC, t;
```

This will return all values in the text column that are sufficiently similar to `word`, sorted from best match to worst. The index will be used to make this a fast operation even over very large data sets.

A variant of the above query is

```
SELECT t, t <-> 'word' AS dist
```

```
FROM test_trgm
ORDER BY dist LIMIT 10;
```

This can be implemented quite efficiently by GiST indexes, but not by GIN indexes. It will usually beat the first formulation when only a small number of the closest matches is wanted.

Also you can use an index on the `t` column for word similarity or strict word similarity. Typical queries are:

```
SELECT t, word_similarity('word', t) AS sml
FROM test_trgm
WHERE 'word' <% t
ORDER BY sml DESC, t;
```

and

```
SELECT t, strict_word_similarity('word', t) AS sml
FROM test_trgm
WHERE 'word' <<% t
ORDER BY sml DESC, t;
```

This will return all values in the text column for which there is a continuous extent in the corresponding ordered trigram set that is sufficiently similar to the trigram set of `word`, sorted from best match to worst. The index will be used to make this a fast operation even over very large data sets.

Possible variants of the above queries are:

```
SELECT t, 'word' <<-> t AS dist
FROM test_trgm
ORDER BY dist LIMIT 10;
```

and

```
SELECT t, 'word' <<<-> t AS dist
FROM test_trgm
ORDER BY dist LIMIT 10;
```

This can be implemented quite efficiently by GiST indexes, but not by GIN indexes.

Beginning in PostgreSQL 9.1, these index types also support index searches for `LIKE` and `ILIKE`, for example

```
SELECT * FROM test_trgm WHERE t LIKE '%foo%bar';
```

The index search works by extracting trigrams from the search string and then looking these up in the index. The more trigrams in the search string, the more effective the index search is. Unlike B-tree based searches, the search string need not be left-anchored.

Beginning in PostgreSQL 9.3, these index types also support index searches for regular-expression matches (`~` and `~*` operators), for example

```
SELECT * FROM test_trgm WHERE t ~ '(foo|bar)';
```

The index search works by extracting trigrams from the regular expression and then looking these up in the index. The more trigrams that can be extracted from the regular expression, the more effective the index search is. Unlike B-tree based searches, the search string need not be left-anchored.

For both `LIKE` and regular-expression searches, keep in mind that a pattern with no extractable trigrams will degenerate to a full-index scan.

The choice between GiST and GIN indexing depends on the relative performance characteristics of GiST and GIN, which are discussed elsewhere.

## F.42.5. Text Search Integration

Trigram matching is a very useful tool when used in conjunction with a full text index. In particular it can help to recognize misspelled input words that will not be matched directly by the full text search mechanism.

The first step is to generate an auxiliary table containing all the unique words in the documents:

```
CREATE TABLE words AS SELECT word FROM
    ts_stat('SELECT to_tsvector(''simple'', bodytext) FROM documents');
```

where `documents` is a table that has a text field `bodytext` that we wish to search. The reason for using the `simple` configuration with the `to_tsvector` function, instead of using a language-specific configuration, is that we want a list of the original (unstemmed) words.

Next, create a trigram index on the word column:

```
CREATE INDEX words_idx ON words USING GIN (word gin_trgm_ops);
```

Now, a `SELECT` query similar to the previous example can be used to suggest spellings for misspelled words in user search terms. A useful extra test is to require that the selected words are also of similar length to the misspelled word.

### Note

Since the `words` table has been generated as a separate, static table, it will need to be periodically regenerated so that it remains reasonably up-to-date with the document collection. Keeping it exactly current is usually unnecessary.

## F.43. pg\_tsparser

`pg_tsparser` is a Postgres Pro extension for text search. This extension modifies the default text parsing strategy for words that include:

- underscores
- numbers and letters separated by the hyphen character

In addition to separate word parts returned by default, `pg_tsparser` also returns the whole word.

### F.43.1. Installation and Setup

`pg_tsparser` is included into the Postgres Pro distribution. To enable `pg_tsparser`, once Postgres Pro is installed, create the `pg_tsparser` extension for each database you are planning to use:

```
CREATE EXTENSION pg_tsparser;
```

Once `pg_tsparser` is enabled, you can create your own text search configuration. In addition to `pg_tsparser`, you can use any available dictionary.

For example, you can create `english_ts` configuration for the English language, as follows:

```
CREATE TEXT SEARCH CONFIGURATION english_ts (
    PARSER = tsparser
);

COMMENT ON TEXT SEARCH CONFIGURATION english_ts IS 'text search configuration for
english language';

ALTER TEXT SEARCH CONFIGURATION english_ts
    ADD MAPPING FOR email, file, float, host, hword_numpart, int,
    numhword, numword, sfloat, uint, url, url_path, version
    WITH simple;

ALTER TEXT SEARCH CONFIGURATION english_ts
    ADD MAPPING FOR asciiword, asciihword, hword_asciipart,
    word, hword, hword_part
    WITH english_stem;
```

## F.43.2. Examples

The following examples illustrate the difference in search results returned by `pg_tsparser` and the default parser:

```
SELECT to_tsvector('english', 'pg_trgm') as def_parser,
       to_tsvector('english_ts', 'pg_trgm') as new_parser;
 def_parser |          new_parser
-----+-----
 'pg':1 'trgm':2 | 'pg':2 'pg_trgm':1 'trgm':3
(1 row)
```

```
SELECT to_tsvector('english', '123-abc') as def_parser,
       to_tsvector('english_ts', '123-abc') as new_parser;
 def_parser |          new_parser
-----+-----
 '123':1 'abc':2 | '123':2 '123-abc':1 'abc':3
(1 row)
```

```
SELECT to_tsvector('english', 'rel-3.2-A') as def_parser,
       to_tsvector('english_ts', 'rel-3.2-A') as new_parser;
 def_parser |          new_parser
-----+-----
 '-3.2':2 'rel':1 | '3.2':3 'rel':2 'rel-3.2-a':1
(1 row)
```

## F.43.3. Authors

Postgres Professional, Moscow, Russia

## F.44. `pg_variables`

The `pg_variables` module provides functions for working with variables of various types. The created variables are only available in the current user session.

## F.44.1. Installation

The `pg_variables` extension is included into Postgres Pro. Once you have Postgres Pro installed, you must execute the `CREATE EXTENSION` command to enable `pg_variables`, as follows:

```
CREATE EXTENSION pg_variables;
```

## F.44.2. Usage

The `pg_variables` module provides several functions for creating, reading, and managing variables of scalar, record, and array types. See the following sections for function descriptions and syntax:

- [Section F.44.3.1](#) describes functions for scalar variables.
- [Section F.44.3.2](#) describes functions for record variables.
- [Section F.44.3.3](#) describes functions for array variables.
- [Section F.44.3.4](#) lists functions you can use to manage all variables in your current session.

For detailed usage examples, see [Section F.44.4](#).

### F.44.2.1. Using Transactional Variables

By default, the created variables are non-transactional. Once successfully set, a variable exists for the whole session, regardless of rollbacks, if any. For example:

```
SELECT pgv_set('vars', 'int1', 101);
BEGIN;
SELECT pgv_set('vars', 'int2', 102);
ROLLBACK;

SELECT * FROM pgv_list() order by package, name;
 package | name | is_transactional
-----+-----+-----
 vars    | int1 | f
 vars    | int2 | f
```

If you would like to use variables that support transactions and savepoints, pass the optional `is_transactional` flag as the last parameter when creating this variable:

```
BEGIN;
SELECT pgv_set('vars', 'trans_int', 101, true);
SAVEPOINT sp1;
SELECT pgv_set('vars', 'trans_int', 102, true);
ROLLBACK TO sp1;
COMMIT;
SELECT pgv_get('vars', 'trans_int', NULL::int);
 pgv_get
-----
      101
```

You must use the `is_transactional` flag every time you change the value of a transactional variable using `pgv_set()` or `pgv_insert()` functions. Otherwise, an error occurs. Other functions do not require this flag.

```
SELECT pgv_insert('pack', 'var_record', row(123::int, 'text'::text), true);

SELECT pgv_insert('pack', 'var_record', row(456::int, 'another text'::text));
ERROR:  variable "var_record" already created as TRANSACTIONAL

SELECT pgv_delete('pack', 'var_record', 123::int);
```

If the `pgv_free()` or `pgv_remove()` function calls are rolled back, the affected transactional variables will be restored, unlike non-transactional variables, which are removed permanently. For example:

```
SELECT pgv_set('pack', 'var_reg', 123);
SELECT pgv_set('pack', 'var_trans', 456, true);
BEGIN;
SELECT pgv_free();
ROLLBACK;
SELECT * FROM pgv_list();
package | name | is_transactional
-----+-----+-----
pack | var_trans | t
```

## F.44.3. Functions

### F.44.3.1. Scalar Variables

The following functions support scalar variables:

Function	Returns
<code>pgv_set(package text, name text, value anynonarray, is_transactional bool default false)</code>	void
<code>pgv_get(package text, name text, var_type anynonarray, strict bool default true)</code>	anynonarray

To use the `pgv_get()` function, you must first create a package and a variable using the `pgv_set()` function. If the specified package or variable does not exist, an error occurs:

```
SELECT pgv_get('vars', 'int1', NULL::int);
ERROR: unrecognized package "vars"

SELECT pgv_get('vars', 'int1', NULL::int);
ERROR: unrecognized variable "int1"
```

`pgv_get()` function checks the variable type. If the specified type does not match the type of the variable, an error is raised:

```
SELECT pgv_get('vars', 'int1', NULL::text);
ERROR: variable "int1" requires "integer" value
```

### F.44.3.2. Records

The following functions support collections of record variables:

Function	Returns	Description
<code>pgv_insert(package text, name text, r record, is_transactional bool default false)</code>	void	Inserts a record into a variable collection for the specified package. If the package or variable does not exist, it is created automatically. The first column of <code>r</code> is the primary key. If a record with the same primary key already exists or this variable collection has another structure, an error is raised.
<code>pgv_update(package text, name text, r record)</code>	boolean	Updates a record with the corresponding primary key

Function	Returns	Description
		(the first column of <code>r</code> is the primary key). Returns <code>true</code> if the record was found. If this variable collection has another structure, an error is raised.
<code>pgv_delete(package text, name text, value anynonarray)</code>	boolean	Deletes a record with the corresponding primary key (the first column of <code>r</code> is the primary key). Returns <code>true</code> if the record was found.
<code>pgv_select(package text, name text)</code>	set of records	Returns the variable collection records.
<code>pgv_select(package text, name text, value anynonarray)</code>	record	Returns the record with the corresponding primary key (the first column of <code>r</code> is a primary key).
<code>pgv_select(package text, name text, value anyarray)</code>	set of records	Returns the variable collection records with the corresponding primary keys (the first column of <code>r</code> is a primary key).

To use `pgv_update()`, `pgv_delete()` and `pgv_select()` functions, you must first create a package and a variable using the `pgv_insert()` function. The variable type and the record type must be the same; otherwise, an error occurs.

### F.44.3.3. Arrays

The following functions support array variables:

Function	Returns
<code>pgv_set(package text, name text, value anyarray, is_transactional bool default false)</code>	void
<code>pgv_get(package text, name text, var_type anyarray, strict bool default true)</code>	anyarray

Usage instructions for these functions are the same as those provided in [Section F.44.3.1](#) for scalar variables.

### F.44.3.4. Miscellaneous Functions

Function	Returns	Description
<code>pgv_exists(package text, name text)</code>	bool	Returns <code>true</code> if the specified package and variable exist.
<code>pgv_exists(package text)</code>	bool	Returns <code>true</code> if the specified package exists.
<code>pgv_remove(package text, name text)</code>	void	Removes the variable with the specified name. The specified package and variable must exist; otherwise, an error is raised.
<code>pgv_remove(package text)</code>	void	Removes the specified package and all the corresponding

Function	Returns	Description
		variables. The specified package must exist; otherwise, an error is raised.
<code>pgv_free()</code>	void	Removes all packages and variables.
<code>pgv_list()</code>	table(package text, name text, is_transactional bool)	Displays all the available variables and the corresponding packages, as well as whether each variable is transactional.
<code>pgv_stats()</code>	table(package text, allocated_memory bigint)	Returns the list of assigned packages and the amount of memory used by variables, in bytes. If you are using transactional variables, this list also includes all deleted packages that still may be restored by a <code>ROLLBACK</code> . This function only supports Postgres Pro 9.6 or higher.

### F.44.3.5. Deprecated Functions

#### F.44.3.5.1. Integer Variables

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

Function	Returns
<code>pgv_set_int(package text, name text, value int, is_transactional bool default false)</code>	void
<code>pgv_get_int(package text, name text, strict bool default true)</code>	int

#### F.44.3.5.2. Text Variables

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

Function	Returns
<code>pgv_set_text(package text, name text, value text, is_transactional bool default false)</code>	void
<code>pgv_get_text(package text, name text, strict bool default true)</code>	text

#### F.44.3.5.3. Numeric Variables

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

Function	Returns
<code>pgv_set_numeric(package text, name text, value numeric, is_transactional bool default false)</code>	void
<code>pgv_get_numeric(package text, name text, strict bool default true)</code>	numeric

**F.44.3.5.4. Timestamp Variables**

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

Function	Returns
<code>pgv_set_timestamp(package text, name text, value timestamp, is_transactional bool default false)</code>	void
<code>pgv_get_timestamp(package text, name text, strict bool default true)</code>	timestamp

**F.44.3.5.5. Timestamp with timezone Variables**

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

Function	Returns
<code>pgv_set_timestamptz(package text, name text, value timestamptz, is_transactional bool default false)</code>	void
<code>pgv_get_timestamptz(package text, name text, strict bool default true)</code>	timestamptz

**F.44.3.5.6. Date Variables**

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

Function	Returns
<code>pgv_set_date(package text, name text, value date, is_transactional bool default false)</code>	void
<code>pgv_get_date(package text, name text, strict bool default true)</code>	date

**F.44.3.5.7. Jsonb Variables**

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

Function	Returns
<code>pgv_set_jsonb(package text, name text, value jsonb, is_transactional bool default false)</code>	void
<code>pgv_get_jsonb(package text, name text, strict bool default true)</code>	jsonb

**F.44.4. Examples**

Define scalar variables using the `pgv_set()` function, and then return their values using the `pgv_get()` function:

```
SELECT pgv_set('vars', 'int1', 101);
SELECT pgv_set('vars', 'int2', 102);
SELECT pgv_set('vars', 'text1', 'text variable'::text);
```

```
SELECT pgv_get('vars', 'int1', NULL::int);
pgv_get
```

```
-----
101
```

```
SELECT pgv_get('vars', 'int2', NULL::int);
pgv_get
-----
      102
```

```
SELECT pgv_get('vars', 'text1', NULL::text);
pgv_get
-----
text variable
```

Let's assume we have the `tab` table and examine several examples of using record variables:

```
CREATE TABLE tab (id int, t varchar);
INSERT INTO tab VALUES (0, 'str00'), (1, 'str11');
```

You can use the following functions to work with record variables:

```
SELECT pgv_insert('vars', 'r1', tab) FROM tab;
```

```
SELECT pgv_select('vars', 'r1');
pgv_select
-----
(1, str11)
(0, str00)
```

```
SELECT pgv_select('vars', 'r1', 1);
pgv_select
-----
(1, str11)
```

```
SELECT pgv_select('vars', 'r1', 0);
pgv_select
-----
(0, str00)
```

```
SELECT pgv_select('vars', 'r1', ARRAY[1, 0]);
pgv_select
-----
(1, str11)
(0, str00)
```

```
SELECT pgv_delete('vars', 'r1', 1);
```

```
SELECT pgv_select('vars', 'r1');
pgv_select
-----
(0, str00)
```

Consider the behavior of a transactional variable `var_text` when changed before and after savepoints:

```
SELECT pgv_set('pack', 'var_text', 'before transaction block'::text, true);
BEGIN;
SELECT pgv_set('pack', 'var_text', 'before savepoint'::text, true);
SAVEPOINT sp1;
SELECT pgv_set('pack', 'var_text', 'savepoint sp1'::text, true);
SAVEPOINT sp2;
SELECT pgv_set('pack', 'var_text', 'savepoint sp2'::text, true);
RELEASE sp2;
SELECT pgv_get('pack', 'var_text', NULL::text);
```

```

pgv_get
-----
savepoint sp2

ROLLBACK TO sp1;
SELECT pgv_get('pack', 'var_text', NULL::text);
      pgv_get
-----
before savepoint

ROLLBACK;
SELECT pgv_get('pack', 'var_text', NULL::text);
      pgv_get
-----
before transaction block

```

If you create a variable after BEGIN or SAVEPOINT statements and then rollback to the previous state, the transactional variable is removed:

```

BEGIN;
SAVEPOINT sp1;
SAVEPOINT sp2;
SELECT pgv_set('pack', 'var_int', 122, true);
RELEASE SAVEPOINT sp2;
SELECT pgv_get('pack', 'var_int', NULL::int);
pgv_get
-----
      122

ROLLBACK TO sp1;
SELECT pgv_get('pack', 'var_int', NULL::int);
ERROR: unrecognized variable "var_int"
COMMIT;

```

List the available packages and variables:

```

SELECT * FROM pgv_list() ORDER BY package, name;
 package | name | is_transactional
-----+-----+-----
 pack    | var_text | t
 vars    | int1     | f
 vars    | int2     | f
 vars    | r1       | f
 vars    | text1    | f

```

Get the amount of memory used by variables, in bytes:

```

SELECT * FROM pgv_stats() ORDER BY package;
 package | allocated_memory
-----+-----
 pack    |          16384
 vars    |          32768

```

Delete the specified variables or packages:

```

SELECT pgv_remove('vars', 'int1');
SELECT pgv_remove('vars');

```

Delete all packages and variables:

```

SELECT pgv_free();

```

## F.44.5. Authors

Postgres Professional, Moscow, Russia

## F.45. `pg_visibility`

The `pg_visibility` module provides a means for examining the visibility map (VM) and page-level visibility information of a table. It also provides functions to check the integrity of a visibility map and to force it to be rebuilt.

Three different bits are used to store information about page-level visibility. The all-visible bit in the visibility map indicates that every tuple in the corresponding page of the relation is visible to every current and future transaction. The all-frozen bit in the visibility map indicates that every tuple in the page is frozen; that is, no future vacuum will need to modify the page until such time as a tuple is inserted, updated, deleted, or locked on that page. The page header's `PD_ALL_VISIBLE` bit has the same meaning as the all-visible bit in the visibility map, but is stored within the data page itself rather than in a separate data structure. These two bits will normally agree, but the page's all-visible bit can sometimes be set while the visibility map bit is clear after a crash recovery. The reported values can also disagree because of a change that occurs after `pg_visibility` examines the visibility map and before it examines the data page. Any event that causes data corruption can also cause these bits to disagree.

Functions that display information about `PD_ALL_VISIBLE` bits are much more costly than those that only consult the visibility map, because they must read the relation's data blocks rather than only the (much smaller) visibility map. Functions that check the relation's data blocks are similarly expensive.

### F.45.1. Functions

`pg_visibility_map`(relation regclass, blkno bigint, all\_visible OUT boolean, all\_frozen OUT boolean) returns record

Returns the all-visible and all-frozen bits in the visibility map for the given block of the given relation.

`pg_visibility`(relation regclass, blkno bigint, all\_visible OUT boolean, all\_frozen OUT boolean, pd\_all\_visible OUT boolean) returns record

Returns the all-visible and all-frozen bits in the visibility map for the given block of the given relation, plus the `PD_ALL_VISIBLE` bit of that block.

`pg_visibility_map`(relation regclass, blkno OUT bigint, all\_visible OUT boolean, all\_frozen OUT boolean) returns setof record

Returns the all-visible and all-frozen bits in the visibility map for each block of the given relation.

`pg_visibility`(relation regclass, blkno OUT bigint, all\_visible OUT boolean, all\_frozen OUT boolean, pd\_all\_visible OUT boolean) returns setof record

Returns the all-visible and all-frozen bits in the visibility map for each block of the given relation, plus the `PD_ALL_VISIBLE` bit of each block.

`pg_visibility_map_summary`(relation regclass, all\_visible OUT bigint, all\_frozen OUT bigint) returns record

Returns the number of all-visible pages and the number of all-frozen pages in the relation according to the visibility map.

`pg_check_frozen`(relation regclass, t\_ctid OUT tid) returns setof tid

Returns the TIDs of non-frozen tuples stored in pages marked all-frozen in the visibility map. If this function returns a non-empty set of TIDs, the visibility map is corrupt.

`pg_check_visible`(relation regclass, t\_ctid OUT tid) returns setof tid

Returns the TIDs of non-all-visible tuples stored in pages marked all-visible in the visibility map. If this function returns a non-empty set of TIDs, the visibility map is corrupt.

`pg_truncate_visibility_map(relation regclass)` returns void

Truncates the visibility map for the given relation. This function is useful if you believe that the visibility map for the relation is corrupt and wish to force rebuilding it. The first `VACUUM` executed on the given relation after this function is executed will scan every page in the relation and rebuild the visibility map. (Until that is done, queries will treat the visibility map as containing all zeroes.)

By default, these functions are executable only by superusers and members of the `pg_stat_scan_tables` role, with the exception of `pg_truncate_visibility_map(relation regclass)` which can only be executed by superusers.

Robert Haas <rhaas@postgresql.org>

## F.46. plantuner

The `plantuner` module provides hints for the planner that can disable or enable indexes for query execution.

### F.46.1. Motivation

In some cases, it may be required to control the planner by providing hints that make the optimizer ignore some parts of its algorithm. There are many situations when a developer may want to temporarily disable specific index(es), without dropping them, or to instruct the planner to use a specific index.

This version of `plantuner` provides a possibility to hide the specified indexes from Postgres Pro planner, so it will not use them. For some workloads, Postgres Pro could be too pessimistic about newly created tables and assume that there are much more rows in a table than it actually has. If the `plantuner.fix_empty_table` GUC variable is set to `true`, `plantuner` sets to zero the number of pages/tuples of the table that has no blocks in a file.

### F.46.2. GUC Variables

`plantuner.disable_index` — list of indexes invisible to planner.

`plantuner.enable_index` — list of indexes visible to planner even if they are hidden by `plantuner.disable_index`.

### F.46.3. Example

To enable the module, you can either load `plantuner` shared library in a `psql` session or specify `shared_preload_libraries` option in `postgresql.conf`.

```
=# LOAD 'plantuner';
=# create table test(id int);
=# create index id_idx on test(id);
=# create index id_idx2 on test(id);
=# \d test
      Table "public.test"
  Column | Type      | Modifiers
-----+-----+-----
   id    | integer  |
Indexes:
    "id_idx" btree (id)
    "id_idx2" btree (id)
=# explain select id from test where id=1;
              QUERY PLAN
-----
Bitmap Heap Scan on test  (cost=4.34..15.03 rows=12 width=4)
  Recheck Cond: (id = 1)
```

```

-> Bitmap Index Scan on id_idx2  (cost=0.00..4.34 rows=12 width=0)
      Index Cond: (id = 1)
(4 rows)
=# set enable_seqscan=off;
=# set plantuner.disable_index='id_idx2';
=# explain select id from test where id=1;
              QUERY PLAN
-----
Bitmap Heap Scan on test  (cost=4.34..15.03 rows=12 width=4)
  Recheck Cond: (id = 1)
    -> Bitmap Index Scan on id_idx  (cost=0.00..4.34 rows=12 width=0)
        Index Cond: (id = 1)
(4 rows)
=# set plantuner.disable_index='id_idx2,id_idx';
=# explain select id from test where id=1;
              QUERY PLAN
-----
Seq Scan on test  (cost=10000000000.00..10000000040.00 rows=12 width=4)
  Filter: (id = 1)
(2 rows)
=# set plantuner.enable_index='id_idx';
=# explain select id from test where id=1;
              QUERY PLAN
-----
Bitmap Heap Scan on test  (cost=4.34..15.03 rows=12 width=4)
  Recheck Cond: (id = 1)
    -> Bitmap Index Scan on id_idx  (cost=0.00..4.34 rows=12 width=0)
        Index Cond: (id = 1)
(4 rows)

```

## F.46.4. Authors

## F.47. postgres\_fdw

The `postgres_fdw` module provides the foreign-data wrapper `postgres_fdw`, which can be used to access data stored in external Postgres Pro servers.

The functionality provided by this module overlaps substantially with the functionality of the older `dblink` module. But `postgres_fdw` provides more transparent and standards-compliant syntax for accessing remote tables, and can give better performance in many cases.

To prepare for remote access using `postgres_fdw`:

1. Install the `postgres_fdw` extension using [CREATE EXTENSION](#).
2. Create a foreign server object, using [CREATE SERVER](#), to represent each remote database you want to connect to. Specify connection information, except `user` and `password`, as options of the server object.
3. Create a user mapping, using [CREATE USER MAPPING](#), for each database user you want to allow to access each foreign server. Specify the remote user name and password to use as `user` and `password` options of the user mapping.
4. Create a foreign table, using [CREATE FOREIGN TABLE](#) or [IMPORT FOREIGN SCHEMA](#), for each remote table you want to access. The columns of the foreign table must match the referenced remote table. You can, however, use table and/or column names different from the remote table's, if you specify the correct remote names as options of the foreign table object.

Now you need only `SELECT` from a foreign table to access the data stored in its underlying remote table. You can also modify the remote table using `INSERT`, `UPDATE`, `DELETE`, or `COPY`. (Of course, the remote user you have specified in your user mapping must have privileges to do these things.)

Note that `postgres_fdw` currently lacks support for `INSERT` statements with an `ON CONFLICT DO UPDATE` clause. However, the `ON CONFLICT DO NOTHING` clause is supported, provided a unique index inference specification is omitted. Note also that `postgres_fdw` supports row movement invoked by `UPDATE` statements executed on partitioned tables, but it currently does not handle the case where a remote partition chosen to insert a moved row into is also an `UPDATE` target partition that will be updated later.

It is generally recommended that the columns of a foreign table be declared with exactly the same data types, and collations if applicable, as the referenced columns of the remote table. Although `postgres_fdw` is currently rather forgiving about performing data type conversions at need, surprising semantic anomalies may arise when types or collations do not match, due to the remote server interpreting query conditions differently from the local server.

Note that a foreign table can be declared with fewer columns, or with a different column order, than its underlying remote table has. Matching of columns to the remote table is by name, not position.

## F.47.1. FDW Options of `postgres_fdw`

### F.47.1.1. Connection Options

A foreign server using the `postgres_fdw` foreign data wrapper can have the same options that `libpq` accepts in connection strings, as described in [Section 31.1.2](#), except that these options are not allowed or have special handling:

- `user`, `password` and `sslpassword` (specify these in a user mapping, instead, or use a service file)
- `client_encoding` (this is automatically set from the local server encoding)
- `fallback_application_name` (always set to `postgres_fdw`)
- `sslkey` and `sslcert` - these may appear in *either or both* a connection and a user mapping. If both are present, the user mapping setting overrides the connection setting.

Only superusers may create or modify user mappings with the `sslcert` or `sslkey` settings.

Only superusers may connect to foreign servers without password authentication, so always specify the `password` option for user mappings belonging to non-superusers.

A superuser may override this check on a per-user-mapping basis by setting the user mapping option `password_required 'false'`, e.g.,

```
ALTER USER MAPPING FOR some_non_superuser SERVER loopback_nopw
OPTIONS (ADD password_required 'false');
```

To prevent unprivileged users from exploiting the authentication rights of the unix user the postgres server is running as to escalate to superuser rights, only the superuser may set this option on a user mapping.

Care is required to ensure that this does not allow the mapped user the ability to connect as superuser to the mapped database per CVE-2007-3278 and CVE-2007-6601. Don't set `password_required=false` on the `public` role. Keep in mind that the mapped user can potentially use any client certificates, `.pgpass`, `.pg_service.conf` etc in the unix home directory of the system user the postgres server runs as. They can also use any trust relationship granted by authentication modes like `peer` or `ident` authentication.

### F.47.1.2. Object Name Options

These options can be used to control the names used in SQL statements sent to the remote Postgres Pro server. These options are needed when a foreign table is created with names different from the underlying remote table's names.

`schema_name`

This option, which can be specified for a foreign table, gives the schema name to use for the foreign table on the remote server. If this option is omitted, the name of the foreign table's schema is used.

`table_name`

This option, which can be specified for a foreign table, gives the table name to use for the foreign table on the remote server. If this option is omitted, the foreign table's name is used.

`column_name`

This option, which can be specified for a column of a foreign table, gives the column name to use for the column on the remote server. If this option is omitted, the column's name is used.

### F.47.1.3. Cost Estimation Options

`postgres_fdw` retrieves remote data by executing queries against remote servers, so ideally the estimated cost of scanning a foreign table should be whatever it costs to be done on the remote server, plus some overhead for communication. The most reliable way to get such an estimate is to ask the remote server and then add something for overhead — but for simple queries, it may not be worth the cost of an additional remote query to get a cost estimate. So `postgres_fdw` provides the following options to control how cost estimation is done:

`use_remote_estimate`

This option, which can be specified for a foreign table or a foreign server, controls whether `postgres_fdw` issues remote `EXPLAIN` commands to obtain cost estimates. A setting for a foreign table overrides any setting for its server, but only for that table. The default is `false`.

`fdw_startup_cost`

This option, which can be specified for a foreign server, is a numeric value that is added to the estimated startup cost of any foreign-table scan on that server. This represents the additional overhead of establishing a connection, parsing and planning the query on the remote side, etc. The default value is `100`.

`fdw_tuple_cost`

This option, which can be specified for a foreign server, is a numeric value that is used as extra cost per-tuple for foreign-table scans on that server. This represents the additional overhead of data transfer between servers. You might increase or decrease this number to reflect higher or lower network delay to the remote server. The default value is `0.01`.

When `use_remote_estimate` is `true`, `postgres_fdw` obtains row count and cost estimates from the remote server and then adds `fdw_startup_cost` and `fdw_tuple_cost` to the cost estimates. When `use_remote_estimate` is `false`, `postgres_fdw` performs local row count and cost estimation and then adds `fdw_startup_cost` and `fdw_tuple_cost` to the cost estimates. This local estimation is unlikely to be very accurate unless local copies of the remote table's statistics are available. Running [ANALYZE](#) on the foreign table is the way to update the local statistics; this will perform a scan of the remote table and then calculate and store statistics just as though the table were local. Keeping local statistics can be a useful way to reduce per-query planning overhead for a remote table — but if the remote table is frequently updated, the local statistics will soon be obsolete.

### F.47.1.4. Remote Execution Options

By default, only `WHERE` clauses using built-in operators and functions will be considered for execution on the remote server. Clauses involving non-built-in functions are checked locally after rows are fetched. If such functions are available on the remote server and can be relied on to produce the same results as they do locally, performance can be improved by sending such `WHERE` clauses for remote execution. This behavior can be controlled using the following option:

#### extensions

This option is a comma-separated list of names of Postgres Pro extensions that are installed, in compatible versions, on both the local and remote servers. Functions and operators that are immutable and belong to a listed extension will be considered shippable to the remote server. This option can only be specified for foreign servers, not per-table.

When using the `extensions` option, *it is the user's responsibility* that the listed extensions exist and behave identically on both the local and remote servers. Otherwise, remote queries may fail or behave unexpectedly.

#### fetch\_size

This option specifies the number of rows `postgres_fdw` should get in each fetch operation. It can be specified for a foreign table or a foreign server. The option specified on a table overrides an option specified for the server. The default is 100.

### F.47.1.5. Updatability Options

By default all foreign tables using `postgres_fdw` are assumed to be updatable. This may be overridden using the following option:

#### updatable

This option controls whether `postgres_fdw` allows foreign tables to be modified using `INSERT`, `UPDATE` and `DELETE` commands. It can be specified for a foreign table or a foreign server. A table-level option overrides a server-level option. The default is `true`.

Of course, if the remote table is not in fact updatable, an error would occur anyway. Use of this option primarily allows the error to be thrown locally without querying the remote server. Note however that the `information_schema` views will report a `postgres_fdw` foreign table to be updatable (or not) according to the setting of this option, without any check of the remote server.

### F.47.1.6. Importing Options

`postgres_fdw` is able to import foreign table definitions using `IMPORT FOREIGN SCHEMA`. This command creates foreign table definitions on the local server that match tables or views present on the remote server. If the remote tables to be imported have columns of user-defined data types, the local server must have compatible types of the same names.

Importing behavior can be customized with the following options (given in the `IMPORT FOREIGN SCHEMA` command):

#### import\_collate

This option controls whether column `COLLATE` options are included in the definitions of foreign tables imported from a foreign server. The default is `true`. You might need to turn this off if the remote server has a different set of collation names than the local server does, which is likely to be the case if it's running on a different operating system. If you do so, however, there is a very severe risk that the imported table columns' collations will not match the underlying data, resulting in anomalous query behavior.

Even when this parameter is set to `true`, importing columns whose collation is the remote server's default can be risky. They will be imported with `COLLATE "default"`, which will select the local server's default collation, which could be different.

#### import\_default

This option controls whether column `DEFAULT` expressions are included in the definitions of foreign tables imported from a foreign server. The default is `false`. If you enable this option, be wary of defaults that might get computed differently on the local server than they would be on the remote server; `nextval()` is a common source of problems. The `IMPORT` will fail altogether if an imported default expression uses a function or operator that does not exist locally.

`import_generated`

This option controls whether column `GENERATED` expressions are included in the definitions of foreign tables imported from a foreign server. The default is `true`. The `IMPORT` will fail altogether if an imported generated expression uses a function or operator that does not exist locally.

`import_not_null`

This option controls whether column `NOT NULL` constraints are included in the definitions of foreign tables imported from a foreign server. The default is `true`.

Note that constraints other than `NOT NULL` will never be imported from the remote tables. Although Postgres Pro does support `CHECK` constraints on foreign tables, there is no provision for importing them automatically, because of the risk that a constraint expression could evaluate differently on the local and remote servers. Any such inconsistency in the behavior of a `CHECK` constraint could lead to hard-to-detect errors in query optimization. So if you wish to import `CHECK` constraints, you must do so manually, and you should verify the semantics of each one carefully. For more detail about the treatment of `CHECK` constraints on foreign tables, see [CREATE FOREIGN TABLE](#).

Tables or foreign tables which are partitions of some other table are automatically excluded. Partitioned tables are imported, unless they are a partition of some other table. Since all data can be accessed through the partitioned table which is the root of the partitioning hierarchy, this approach should allow access to all the data without creating extra objects.

## F.47.2. Connection Management

`postgres_fdw` establishes a connection to a foreign server during the first query that uses a foreign table associated with the foreign server. This connection is kept and re-used for subsequent queries in the same session. However, if multiple user identities (user mappings) are used to access the foreign server, a connection is established for each user mapping.

## F.47.3. Transaction Management

During a query that references any remote tables on a foreign server, `postgres_fdw` opens a transaction on the remote server if one is not already open corresponding to the current local transaction. The remote transaction is committed or aborted when the local transaction commits or aborts. Savepoints are similarly managed by creating corresponding remote savepoints.

The remote transaction uses `SERIALIZABLE` isolation level when the local transaction has `SERIALIZABLE` isolation level; otherwise it uses `REPEATABLE READ` isolation level. This choice ensures that if a query performs multiple table scans on the remote server, it will get snapshot-consistent results for all the scans. A consequence is that successive queries within a single transaction will see the same data from the remote server, even if concurrent updates are occurring on the remote server due to other activities. That behavior would be expected anyway if the local transaction uses `SERIALIZABLE` or `REPEATABLE READ` isolation level, but it might be surprising for a `READ COMMITTED` local transaction. A future Postgres Pro release might modify these rules.

Note that it is currently not supported by `postgres_fdw` to prepare the remote transaction for two-phase commit.

## F.47.4. Remote Query Optimization

`postgres_fdw` attempts to optimize remote queries to reduce the amount of data transferred from foreign servers. This is done by sending query `WHERE` clauses to the remote server for execution, and by not retrieving table columns that are not needed for the current query. To reduce the risk of misexecution of queries, `WHERE` clauses are not sent to the remote server unless they use only data types, operators, and functions that are built-in or belong to an extension that's listed in the foreign server's `extensions` option. Operators and functions in such clauses must be `IMMUTABLE` as well. For an `UPDATE` or `DELETE` query, `postgres_fdw` attempts to optimize the query execution by sending the whole query to the remote server if there are no query `WHERE` clauses that cannot be sent to the remote server, no local joins for

the query, no row-level local `BEFORE` or `AFTER` triggers or stored generated columns on the target table, and no `CHECK OPTION` constraints from parent views. In `UPDATE`, expressions to assign to target columns must use only built-in data types, `IMMUTABLE` operators, or `IMMUTABLE` functions, to reduce the risk of misexecution of the query.

When `postgres_fdw` encounters a join between foreign tables on the same foreign server, it sends the entire join to the foreign server, unless for some reason it believes that it will be more efficient to fetch rows from each table individually, or unless the table references involved are subject to different user mappings. While sending the `JOIN` clauses, it takes the same precautions as mentioned above for the `WHERE` clauses.

The query that is actually sent to the remote server for execution can be examined using `EXPLAIN VERBOSE`.

## F.47.5. Remote Query Execution Environment

In the remote sessions opened by `postgres_fdw`, the `search_path` parameter is set to just `pg_catalog`, so that only built-in objects are visible without schema qualification. This is not an issue for queries generated by `postgres_fdw` itself, because it always supplies such qualification. However, this can pose a hazard for functions that are executed on the remote server via triggers or rules on remote tables. For example, if a remote table is actually a view, any functions used in that view will be executed with the restricted search path. It is recommended to schema-qualify all names in such functions, or else attach `SET search_path` options (see [CREATE FUNCTION](#)) to such functions to establish their expected search path environment.

`postgres_fdw` likewise establishes remote session settings for various parameters:

- `TimeZone` is set to `UTC`
- `DateStyle` is set to `ISO`
- `IntervalStyle` is set to `postgres`
- `extra_float_digits` is set to 3 for remote servers 9.0 and newer and is set to 2 for older versions

These are less likely to be problematic than `search_path`, but can be handled with function `SET` options if the need arises.

It is *not* recommended that you override this behavior by changing the session-level settings of these parameters; that is likely to cause `postgres_fdw` to malfunction.

## F.47.6. Cross-Version Compatibility

`postgres_fdw` can be used with remote servers dating back to PostgreSQL 8.3. Read-only capability is available back to 8.1. A limitation however is that `postgres_fdw` generally assumes that immutable built-in functions and operators are safe to send to the remote server for execution, if they appear in a `WHERE` clause for a foreign table. Thus, a built-in function that was added since the remote server's release might be sent to it for execution, resulting in “function does not exist” or a similar error. This type of failure can be worked around by rewriting the query, for example by embedding the foreign table reference in a sub-`SELECT` with `OFFSET 0` as an optimization fence, and placing the problematic function or operator outside the sub-`SELECT`.

## F.47.7. Examples

Here is an example of creating a foreign table with `postgres_fdw`. First install the extension:

```
CREATE EXTENSION postgres_fdw;
```

Then create a foreign server using [CREATE SERVER](#). In this example we wish to connect to a Postgres Pro server on host `192.83.123.89` listening on port `5432`. The database to which the connection is made is named `foreign_db` on the remote server:

```
CREATE SERVER foreign_server
    FOREIGN DATA WRAPPER postgres_fdw
    OPTIONS (host '192.83.123.89', port '5432', dbname 'foreign_db');
```

A user mapping, defined with [CREATE USER MAPPING](#), is needed as well to identify the role that will be used on the remote server:

```
CREATE USER MAPPING FOR local_user
    SERVER foreign_server
    OPTIONS (user 'foreign_user', password 'password');
```

Now it is possible to create a foreign table with [CREATE FOREIGN TABLE](#). In this example we wish to access the table named `some_schema.some_table` on the remote server. The local name for it will be `foreign_table`:

```
CREATE FOREIGN TABLE foreign_table (
    id integer NOT NULL,
    data text
)
    SERVER foreign_server
    OPTIONS (schema_name 'some_schema', table_name 'some_table');
```

It's essential that the data types and other properties of the columns declared in `CREATE FOREIGN TABLE` match the actual remote table. Column names must match as well, unless you attach `column_name` options to the individual columns to show how they are named in the remote table. In many cases, use of [IMPORT FOREIGN SCHEMA](#) is preferable to constructing foreign table definitions manually.

Shigeru Hanada <shigeru.hanada@gmail.com>

## F.48. ptrack

PTRACK is a block-level incremental backup engine for Postgres Pro. If PTRACK is enabled, backup tools like [pg\\_probackup](#) can use its API to get information on the changed blocks on the fly when taking incremental backups. Copying only those blocks that have changed since the previous backup can significantly speed up the creation and minimize the size of backups.

PTRACK is designed to allow false positives, but to never allow false negatives: it means that all changes within the data directory except hint bits are guaranteed to be marked in the PTRACK map file, although some unchanged blocks might be included as well.

### F.48.1. Setting up PTRACK

Once you complete Postgres Pro Standard installation, do the following:

1. Add `ptrack` to the [shared\\_preload\\_libraries](#) parameter in the `postgresql.conf` file:

```
shared_preload_libraries = 'ptrack'
```

2. Set [ptrack.map\\_size](#) parameter to a positive integer.

For optimal performance, it is recommended to set `ptrack.map_size` to  $N / 1024$ , where  $N$  is the size of the Postgres Pro cluster, in MB. If you set this parameter to a lower value, PTRACK is more likely to map several blocks together, which leads to false-positive results when tracking changed blocks and increases the incremental backup size as unchanged blocks can also be copied into the incremental backup.

Setting `ptrack.map_size` to a higher value does not affect PTRACK operation, but keep in mind that you need up to `ptrack.map_size * 3` MB of additional disk space since PTRACK uses two additional temporary files to ensure durability. It is not recommended to set this parameter to a value higher than 1024. Even for Postgres Pro clusters with  $N > 1$  TB, it makes sense to use a higher value only if the efficiency and sizes of backups are more critical than the potential overhead of maintaining a large PTRACK map.

3. Check the [wal\\_level](#) setting. When using PTRACK, it is required to set the [wal\\_level](#) parameter to `replica` or higher. Otherwise, you can lose some tracked changes if crash-recovery occurs: some

commands do not write WAL at all if `wal_level` is `minimal`, and PTRACK map files are flushed to disk only at checkpoint time.

- Restart the Postgres Pro Standard instance for the changes to take effect, and then create the PTRACK extension:

```
CREATE EXTENSION ptrack;
```

As a result, several PTRACK functions are created, which are required for accessing PTRACK data.

Once this setup is complete, PTRACK starts tracking all the page changes in the Postgres Pro cluster and creates a `ptrack.map` file that stores the latest LSN values for these pages.

### Note

The `ptrack.map_size` parameter can only be set at server start. If you change this parameter, the previously created PTRACK map file is cleared, and tracking newly changed blocks starts from scratch. To avoid losing recent changes, it is recommended to retake a full backup after modifying this setting.

## F.48.2. PTRACK Configuration Parameters

`ptrack.map_size` (integer)

Specifies the size of a PTRACK map file and the amount of shared memory allocated for this file, in MB. The PTRACK map file stores the latest LSN values for all pages of the Postgres Pro cluster that have changed since PTRACK was enabled. It is not recommended to set this parameter to a value higher than 1GB. The -1 value disables PTRACK, while the 0 value both disables PTRACK and cleans up all the related service files.

The `ptrack.map_size` parameter can only be set at server start. If you change this parameter, the previously created PTRACK map file is cleared, and tracking newly changed blocks starts from scratch. To avoid losing recent changes, it is recommended to retake a full backup after modifying this setting.

Default: -1

## F.48.3. PTRACK Functions

`ptrack_init_lsn()` returns `pg_lsn`

Returns the LSN of the last PTRACK map initialization.

`ptrack_get_pagemapset(start_lsn pg_lsn)` returns `setof record`

Returns a list of data files changed since the specified `start_lsn` with the number and bitmap of changed pages for each file.

For example:

```
postgres=# SELECT * FROM ptrack_get_pagemapset('0/185C8C0');
      path      | pagecount |          pagemap
-----+-----+-----
base/16384/1255 |         3 | \x00100000000050000000000000
base/16384/2674 |         3 | \x0000000900010000000000000000
base/16384/2691 |         1 | \x0000400000000000000000000000
base/16384/2608 |         1 | \x00000000000000004000000000000000
base/16384/2690 |         1 | \x0004000000000000000000000000
```

`ptrack_get_change_stat(start_lsn pg_lsn)` returns `record`

Returns the statistics of changes (number of files, number of changed pages and their total size in MB) since the specified `start_lsn`.

For example:

```
postgres=# SELECT * FROM ptrack_get_change_stat('0/285C8C8');
 files | pages |          size, MB
-----+-----+-----
    20 |    25 | 0.19531250000000000000
```

ptrack\_version() returns text

Returns PTRACK version.

## F.49. seg

This module implements a data type `seg` for representing line segments, or floating point intervals. `seg` can represent uncertainty in the interval endpoints, making it especially useful for representing laboratory measurements.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.49.1. Rationale

The geometry of measurements is usually more complex than that of a point in a numeric continuum. A measurement is usually a segment of that continuum with somewhat fuzzy limits. The measurements come out as intervals because of uncertainty and randomness, as well as because the value being measured may naturally be an interval indicating some condition, such as the temperature range of stability of a protein.

Using just common sense, it appears more convenient to store such data as intervals, rather than pairs of numbers. In practice, it even turns out more efficient in most applications.

Further along the line of common sense, the fuzziness of the limits suggests that the use of traditional numeric data types leads to a certain loss of information. Consider this: your instrument reads 6.50, and you input this reading into the database. What do you get when you fetch it? Watch:

```
test=> select 6.50 :: float8 as "pH";
 pH
---
6.5
(1 row)
```

In the world of measurements, 6.50 is not the same as 6.5. It may sometimes be critically different. The experimenters usually write down (and publish) the digits they trust. 6.50 is actually a fuzzy interval contained within a bigger and even fuzzier interval, 6.5, with their center points being (probably) the only common feature they share. We definitely do not want such different data items to appear the same.

Conclusion? It is nice to have a special data type that can record the limits of an interval with arbitrarily variable precision. Variable in the sense that each data element records its own precision.

Check this out:

```
test=> select '6.25 .. 6.50'::seg as "pH";
 pH
-----
6.25 .. 6.50
(1 row)
```

### F.49.2. Syntax

The external representation of an interval is formed using one or two floating-point numbers joined by the range operator (`..` or `...`). Alternatively, it can be specified as a center point plus or minus a deviation. Optional certainty indicators (`<`, `>` or `~`) can be stored as well. (Certainty indicators are ignored by all

the built-in operators, however.) [Table F.90](#) gives an overview of allowed representations; [Table F.91](#) shows some examples.

In [Table F.90](#),  $x$ ,  $y$ , and  $delta$  denote floating-point numbers.  $x$  and  $y$ , but not  $delta$ , can be preceded by a certainty indicator.

**Table F.90. `seg` External Representations**

$x$	Single value (zero-length interval)
$x .. y$	Interval from $x$ to $y$
$x (+-) delta$	Interval from $x - delta$ to $x + delta$
$x ..$	Open interval with lower bound $x$
$.. x$	Open interval with upper bound $x$

**Table F.91. Examples of Valid `seg` Input**

5.0	Creates a zero-length segment (a point, if you will)
~5.0	Creates a zero-length segment and records ~ in the data. ~ is ignored by <code>seg</code> operations, but is preserved as a comment.
<5.0	Creates a point at 5.0. < is ignored but is preserved as a comment.
>5.0	Creates a point at 5.0. > is ignored but is preserved as a comment.
5(+-)0.3	Creates an interval 4.7 .. 5.3. Note that the (+-) notation isn't preserved.
50 ..	Everything that is greater than or equal to 50
.. 0	Everything that is less than or equal to 0
1.5e-2 .. 2E-2	Creates an interval 0.015 .. 0.02
1 ... 2	The same as 1...2, or 1 .. 2, or 1..2 (spaces around the range operator are ignored)

Because the ... operator is widely used in data sources, it is allowed as an alternative spelling of the .. operator. Unfortunately, this creates a parsing ambiguity: it is not clear whether the upper bound in 0...23 is meant to be 23 or 0.23. This is resolved by requiring at least one digit before the decimal point in all numbers in `seg` input.

As a sanity check, `seg` rejects intervals with the lower bound greater than the upper, for example 5 .. 2.

### F.49.3. Precision

`seg` values are stored internally as pairs of 32-bit floating point numbers. This means that numbers with more than 7 significant digits will be truncated.

Numbers with 7 or fewer significant digits retain their original precision. That is, if your query returns 0.00, you will be sure that the trailing zeroes are not the artifacts of formatting: they reflect the precision of the original data. The number of leading zeroes does not affect precision: the value 0.0067 is considered to have just 2 significant digits.

### F.49.4. Usage

The `seg` module includes a GiST index operator class for `seg` values. The operators supported by the GiST operator class are shown in [Table F.92](#).

**Table F.92. `Seg` GiST Operators**

Operator	Description
<code>seg &lt;&lt; seg</code>	<code>→ boolean</code>

Operator	Description
	Is the first <code>seg</code> entirely to the left of the second? <code>[a, b] &lt;&lt; [c, d]</code> is true if <code>b &lt; c</code> .
<code>seg &gt;&gt; seg</code> → boolean	Is the first <code>seg</code> entirely to the right of the second? <code>[a, b] &gt;&gt; [c, d]</code> is true if <code>a &gt; d</code> .
<code>seg &amp;&lt; seg</code> → boolean	Does the first <code>seg</code> not extend to the right of the second? <code>[a, b] &amp;&lt; [c, d]</code> is true if <code>b &lt;= d</code> .
<code>seg &amp;&gt; seg</code> → boolean	Does the first <code>seg</code> not extend to the left of the second? <code>[a, b] &amp;&gt; [c, d]</code> is true if <code>a &gt;= c</code> .
<code>seg = seg</code> → boolean	Are the two <code>segs</code> equal?
<code>seg &amp;&amp; seg</code> → boolean	Do the two <code>segs</code> overlap?
<code>seg @&gt; seg</code> → boolean	Does the first <code>seg</code> contain the second?
<code>seg &lt;@ seg</code> → boolean	Is the first <code>seg</code> contained in the second?

(Before PostgreSQL 8.2, the containment operators `@>` and `<@` were respectively called `@` and `~`. These names are still available, but are deprecated and will eventually be retired. Notice that the old names are reversed from the convention formerly followed by the core geometric data types!)

In addition to the above operators, the usual comparison operators shown in [Table 9.1](#) are available for type `seg`. These operators first compare (a) to (c), and if these are equal, compare (b) to (d). That results in reasonably good sorting in most cases, which is useful if you want to use `ORDER BY` with this type.

## F.49.5. Notes

For examples of usage, see the regression test `sql/seg.sql`.

The mechanism that converts `(+-)` to regular ranges isn't completely accurate in determining the number of significant digits for the boundaries. For example, it adds an extra digit to the lower boundary if the resulting interval includes a power of ten:

```
postgres=> select '10(+-)1'::seg as seg;
      seg
-----
9.0 .. 11          -- should be: 9 .. 11
```

The performance of an R-tree index can largely depend on the initial order of input values. It may be very helpful to sort the input table on the `seg` column; see the script `sort-segments.pl` for an example.

## F.49.6. Credits

Original author: Gene Selkov, Jr. <selkovjr@mcs.anl.gov>, Mathematics and Computer Science Division, Argonne National Laboratory.

My thanks are primarily to Prof. Joe Hellerstein (<https://dsf.berkeley.edu/jmh/>) for elucidating the gist of the GiST (<http://gist.cs.berkeley.edu/>). I am also grateful to all Postgres developers, present and past, for enabling myself to create my own world and live undisturbed in it. And I would like to acknowledge my gratitude to Argonne Lab and to the U.S. Department of Energy for the years of faithful support of my database research.

## F.50. sepgsql

`sepgsql` is a loadable module that supports label-based mandatory access control (MAC) based on SELinux security policy.

### Warning

The current implementation has significant limitations, and does not enforce mandatory access control for all actions. See [Section F.50.7](#).

## F.50.1. Overview

This module integrates with SELinux to provide an additional layer of security checking above and beyond what is normally provided by Postgres Pro. From the perspective of SELinux, this module allows Postgres Pro to function as a user-space object manager. Each table or function access initiated by a DML query will be checked against the system security policy. This check is in addition to the usual SQL permissions checking performed by Postgres Pro.

SELinux access control decisions are made using security labels, which are represented by strings such as `system_u:object_r:sepgsql_table_t:s0`. Each access control decision involves two labels: the label of the subject attempting to perform the action, and the label of the object on which the operation is to be performed. Since these labels can be applied to any sort of object, access control decisions for objects stored within the database can be (and, with this module, are) subjected to the same general criteria used for objects of any other type, such as files. This design is intended to allow a centralized security policy to protect information assets independent of the particulars of how those assets are stored.

The [SECURITY LABEL](#) statement allows assignment of a security label to a database object.

## F.50.2. Installation

`sepgsql` can only be used on Linux 2.6.28 or higher with SELinux enabled. It is not available on any other platform. You will also need `libselinux` 2.1.10 or higher and `selinux-policy` 3.9.13 or higher (although some distributions may backport the necessary rules into older policy versions).

The `sestatus` command allows you to check the status of SELinux. A typical display is:

```
$ sestatus
SELinux status:                enabled
SELinuxfs mount:              /selinux
Current mode:                  enforcing
Mode from config file:         enforcing
Policy version:                24
Policy from config file:       targeted
```

If SELinux is disabled or not installed, you must set that product up first before installing this module.

To build this module, include the option `--with-selinux` in your Postgres Pro `configure` command. Be sure that the `libselinux-devel` RPM is installed at build time.

To use this module, you must include `sepgsql` in the [shared\\_preload\\_libraries](#) parameter in `postgresql.conf`. The module will not function correctly if loaded in any other manner. Once the module is loaded, you should execute `sepgsql.sql` in each database. This will install functions needed for security label management, and assign initial security labels.

Here is an example showing how to initialize a fresh database cluster with `sepgsql` functions and security labels installed. Adjust the paths shown as appropriate for your installation:

```
$ export PGDATA=/path/to/data/directory
$ initdb
$ vi $PGDATA/postgresql.conf
change
    #shared_preload_libraries = ''                # (change requires restart)
```

```
to
  shared_preload_libraries = 'sepgsql'          # (change requires restart)
$ for DBNAME in template0 template1 postgres; do
  postgres --single -F -c exit_on_error=true $DBNAME \
    </usr/local/pgsql/share/contrib/sepgsql.sql >/dev/null
done
```

Please note that you may see some or all of the following notifications depending on the particular versions you have of `libselenium` and `selinux-policy`:

```
/etc/selinux/targeted/contexts/sepgsql_contexts: line 33 has invalid object type
db_blobs
/etc/selinux/targeted/contexts/sepgsql_contexts: line 36 has invalid object type
db_language
/etc/selinux/targeted/contexts/sepgsql_contexts: line 37 has invalid object type
db_language
/etc/selinux/targeted/contexts/sepgsql_contexts: line 38 has invalid object type
db_language
/etc/selinux/targeted/contexts/sepgsql_contexts: line 39 has invalid object type
db_language
/etc/selinux/targeted/contexts/sepgsql_contexts: line 40 has invalid object type
db_language
```

These messages are harmless and should be ignored.

If the installation process completes without error, you can now start the server normally.

### F.50.3. Regression Tests

Due to the nature of SELinux, running the regression tests for `sepgsql` requires several extra configuration steps, some of which must be done as root. The regression tests will not be run by an ordinary `make check` or `make installcheck` command; you must set up the configuration and then invoke the test script manually. The tests must be run in the `contrib/sepgsql` directory of a configured Postgres Pro build tree. Although they require a build tree, the tests are designed to be executed against an installed server, that is they are comparable to `make installcheck` not `make check`.

First, set up `sepgsql` in a working database according to the instructions in [Section F.50.2](#). Note that the current operating system user must be able to connect to the database as superuser without password authentication.

Second, build and install the policy package for the regression test. The `sepgsql-regtest` policy is a special purpose policy package which provides a set of rules to be allowed during the regression tests. It should be built from the policy source file `sepgsql-regtest.te`, which is done using `make` with a Makefile supplied by SELinux. You will need to locate the appropriate Makefile on your system; the path shown below is only an example. (This Makefile is usually supplied by the `selinux-policy-devel` or `selinux-policy` RPM.) Once built, install this policy package using the `semodule` command, which loads supplied policy packages into the kernel. If the package is correctly installed, `semodule -l` should list `sepgsql-regtest` as an available policy package:

```
$ cd ../contrib/sepgsql
$ make -f /usr/share/selinux/devel/Makefile
$ sudo semodule -u sepgsql-regtest.pp
$ sudo semodule -l | grep sepgsql
sepgsql-regtest 1.07
```

Third, turn on `sepgsql_regression_test_mode`. For security reasons, the rules in `sepgsql-regtest` are not enabled by default; the `sepgsql_regression_test_mode` parameter enables the rules needed to launch the regression tests. It can be turned on using the `setsebool` command:

```
$ sudo setsebool sepgsql_regression_test_mode on
$ getsebool sepgsql_regression_test_mode
```

```
sepgsql_regression_test_mode --> on
```

Fourth, verify your shell is operating in the `unconfined_t` domain:

```
$ id -Z
unconfined_u:unconfined_r:unconfined_t:s0-s0:c0.c1023
```

See [Section F.50.8](#) for details on adjusting your working domain, if necessary.

Finally, run the regression test script:

```
$ ./test_sepgsql
```

This script will attempt to verify that you have done all the configuration steps correctly, and then it will run the regression tests for the `sepgsql` module.

After completing the tests, it's recommended you disable the `sepgsql_regression_test_mode` parameter:

```
$ sudo setsebool sepgsql_regression_test_mode off
```

You might prefer to remove the `sepgsql-regtest` policy entirely:

```
$ sudo semodule -r sepgsql-regtest
```

## F.50.4. GUC Parameters

`sepgsql.permissive` (boolean)

This parameter enables `sepgsql` to function in permissive mode, regardless of the system setting. The default is off. This parameter can only be set in the `postgresql.conf` file or on the server command line.

When this parameter is on, `sepgsql` functions in permissive mode, even if SELinux in general is working in enforcing mode. This parameter is primarily useful for testing purposes.

`sepgsql.debug_audit` (boolean)

This parameter enables the printing of audit messages regardless of the system policy settings. The default is off, which means that messages will be printed according to the system settings.

The security policy of SELinux also has rules to control whether or not particular accesses are logged. By default, access violations are logged, but allowed accesses are not.

This parameter forces all possible logging to be turned on, regardless of the system policy.

## F.50.5. Features

### F.50.5.1. Controlled Object Classes

The security model of SELinux describes all the access control rules as relationships between a subject entity (typically, a client of the database) and an object entity (such as a database object), each of which is identified by a security label. If access to an unlabeled object is attempted, the object is treated as if it were assigned the label `unlabeled_t`.

Currently, `sepgsql` allows security labels to be assigned to schemas, tables, columns, sequences, views, and functions. When `sepgsql` is in use, security labels are automatically assigned to supported database objects at creation time. This label is called a default security label, and is decided according to the system security policy, which takes as input the creator's label, the label assigned to the new object's parent object and optionally name of the constructed object.

A new database object basically inherits the security label of the parent object, except when the security policy has special rules known as type-transition rules, in which case a different label may be applied. For schemas, the parent object is the current database; for tables, sequences, views, and functions, it is the containing schema; for columns, it is the containing table.

### F.50.5.2. DML Permissions

For tables, `db_table:select`, `db_table:insert`, `db_table:update` or `db_table:delete` are checked for all the referenced target tables depending on the kind of statement; in addition, `db_table:select` is also checked for all the tables that contain columns referenced in the `WHERE` or `RETURNING` clause, as a data source for `UPDATE`, and so on.

Column-level permissions will also be checked for each referenced column. `db_column:select` is checked on not only the columns being read using `SELECT`, but those being referenced in other DML statements; `db_column:update` or `db_column:insert` will also be checked for columns being modified by `UPDATE` or `INSERT`.

For example, consider:

```
UPDATE t1 SET x = 2, y = func1(y) WHERE z = 100;
```

Here, `db_column:update` will be checked for `t1.x`, since it is being updated, `db_column:{select update}` will be checked for `t1.y`, since it is both updated and referenced, and `db_column:select` will be checked for `t1.z`, since it is only referenced. `db_table:{select update}` will also be checked at the table level.

For sequences, `db_sequence:get_value` is checked when we reference a sequence object using `SELECT`; however, note that we do not currently check permissions on execution of corresponding functions such as `lastval()`.

For views, `db_view:expand` will be checked, then any other required permissions will be checked on the objects being expanded from the view, individually.

For functions, `db_procedure:{execute}` will be checked when user tries to execute a function as a part of query, or using fast-path invocation. If this function is a trusted procedure, it also checks `db_procedure:{entrypoint}` permission to check whether it can perform as entry point of trusted procedure.

In order to access any schema object, `db_schema:search` permission is required on the containing schema. When an object is referenced without schema qualification, schemas on which this permission is not present will not be searched (just as if the user did not have `USAGE` privilege on the schema). If an explicit schema qualification is present, an error will occur if the user does not have the requisite permission on the named schema.

The client must be allowed to access all referenced tables and columns, even if they originated from views which were then expanded, so that we apply consistent access control rules independent of the manner in which the table contents are referenced.

The default database privilege system allows database superusers to modify system catalogs using DML commands, and reference or modify toast tables. These operations are prohibited when `sepgsql` is enabled.

### F.50.5.3. DDL Permissions

SELinux defines several permissions to control common operations for each object type; such as creation, alter, drop and relabel of security label. In addition, several object types have special permissions to control their characteristic operations; such as addition or deletion of name entries within a particular schema.

Creating a new database object requires `create` permission. SELinux will grant or deny this permission based on the client's security label and the proposed security label for the new object. In some cases, additional privileges are required:

- `CREATE DATABASE` additionally requires `getattr` permission for the source or template database.
- Creating a schema object additionally requires `add_name` permission on the parent schema.
- Creating a table additionally requires permission to create each individual table column, just as if each table column were a separate top-level object.

- Creating a function marked as `LEAKPROOF` additionally requires `install` permission. (This permission is also checked when `LEAKPROOF` is set for an existing function.)

When `DROP` command is executed, `drop` will be checked on the object being removed. Permissions will be also checked for objects dropped indirectly via `CASCADE`. Deletion of objects contained within a particular schema (tables, views, sequences and procedures) additionally requires `remove_name` on the schema.

When `ALTER` command is executed, `setattr` will be checked on the object being modified for each object types, except for subsidiary objects such as the indexes or triggers of a table, where permissions are instead checked on the parent object. In some cases, additional permissions are required:

- Moving an object to a new schema additionally requires `remove_name` permission on the old schema and `add_name` permission on the new one.
- Setting the `LEAKPROOF` attribute on a function requires `install` permission.
- Using `SECURITY LABEL` on an object additionally requires `relabelfrom` permission for the object in conjunction with its old security label and `relabelto` permission for the object in conjunction with its new security label. (In cases where multiple label providers are installed and the user tries to set a security label, but it is not managed by SELinux, only `setattr` should be checked here. This is currently not done due to implementation restrictions.)

#### F.50.5.4. Trusted Procedures

Trusted procedures are similar to security definer functions or `setuid` commands. SELinux provides a feature to allow trusted code to run using a security label different from that of the client, generally for the purpose of providing highly controlled access to sensitive data (e.g., rows might be omitted, or the precision of stored values might be reduced). Whether or not a function acts as a trusted procedure is controlled by its security label and the operating system security policy. For example:

```
postgres=# CREATE TABLE customer (
           cid      int primary key,
           cname    text,
           credit   text
        );
CREATE TABLE
postgres=# SECURITY LABEL ON COLUMN customer.credit
           IS 'system_u:object_r:sepgsql_secret_table_t:s0';
SECURITY LABEL
postgres=# CREATE FUNCTION show_credit(int) RETURNS text
           AS 'SELECT regexp_replace(credit, ''-[0-9]+$$'', ''-xxxx'', 'g')
           FROM customer WHERE cid = $1'
           LANGUAGE sql;
CREATE FUNCTION
postgres=# SECURITY LABEL ON FUNCTION show_credit(int)
           IS 'system_u:object_r:sepgsql_trusted_proc_exec_t:s0';
SECURITY LABEL
```

The above operations should be performed by an administrative user.

```
postgres=# SELECT * FROM customer;
ERROR:  SELinux: security policy violation
postgres=# SELECT cid, cname, show_credit(cid) FROM customer;
 cid | cname | show_credit
-----+-----+-----
  1 | taro  | 1111-2222-3333-xxxx
  2 | hanako | 5555-6666-7777-xxxx
(2 rows)
```

In this case, a regular user cannot reference `customer.credit` directly, but a trusted procedure `show_credit` allows the user to print the credit card numbers of customers with some of the digits masked out.

### F.50.5.5. Dynamic Domain Transitions

It is possible to use SELinux's dynamic domain transition feature to switch the security label of the client process, the client domain, to a new context, if that is allowed by the security policy. The client domain needs the `setcurrent` permission and also `dyntransition` from the old to the new domain.

Dynamic domain transitions should be considered carefully, because they allow users to switch their label, and therefore their privileges, at their option, rather than (as in the case of a trusted procedure) as mandated by the system. Thus, the `dyntransition` permission is only considered safe when used to switch to a domain with a smaller set of privileges than the original one. For example:

```

regression=# select sepysql_getcon();
                sepysql_getcon
-----
unconfined_u:unconfined_r:unconfined_t:s0-s0:c0.c1023
(1 row)

regression=# SELECT sepysql_setcon('unconfined_u:unconfined_r:unconfined_t:s0-
s0:c1.c4');
                sepysql_setcon
-----
t
(1 row)

regression=# SELECT sepysql_setcon('unconfined_u:unconfined_r:unconfined_t:s0-
s0:c1.c1023');
ERROR:  SELinux: security policy violation

```

In this example above we were allowed to switch from the larger MCS range `c1.c1023` to the smaller range `c1.c4`, but switching back was denied.

A combination of dynamic domain transition and trusted procedure enables an interesting use case that fits the typical process life-cycle of connection pooling software. Even if your connection pooling software is not allowed to run most of SQL commands, you can allow it to switch the security label of the client using the `sepysql_setcon()` function from within a trusted procedure; that should take some credential to authorize the request to switch the client label. After that, this session will have the privileges of the target user, rather than the connection pooler. The connection pooler can later revert the security label change by again using `sepysql_setcon()` with `NULL` argument, again invoked from within a trusted procedure with appropriate permissions checks. The point here is that only the trusted procedure actually has permission to change the effective security label, and only does so when given proper credentials. Of course, for secure operation, the credential store (table, procedure definition, or whatever) must be protected from unauthorized access.

### F.50.5.6. Miscellaneous

We reject the `LOAD` command across the board, because any module loaded could easily circumvent security policy enforcement.

## F.50.6. Sepysql Functions

Table F.93 shows the available functions.

**Table F.93. Sepysql Functions**

Function	Description
<code>sepysql_getcon ()</code> → text	Returns the client domain, the current security label of the client.
<code>sepysql_setcon (text)</code> → boolean	

Function	Description
	Switches the client domain of the current session to the new domain, if allowed by the security policy. It also accepts <code>NULL</code> input as a request to transition to the client's original domain.
<code>sepgsql_mcstrans_in (text) → text</code>	Translates the given qualified MLS/MCS range into raw format if the mcstrans daemon is running.
<code>sepgsql_mcstrans_out (text) → text</code>	Translates the given raw MLS/MCS range into qualified format if the mcstrans daemon is running.
<code>sepgsql_restorecon (text) → boolean</code>	Sets up initial security labels for all objects within the current database. The argument may be <code>NULL</code> , or the name of a specfile to be used as alternative of the system default.

## F.50.7. Limitations

### Data Definition Language (DDL) Permissions

Due to implementation restrictions, some DDL operations do not check permissions.

### Data Control Language (DCL) Permissions

Due to implementation restrictions, DCL operations do not check permissions.

### Row-level access control

Postgres Pro supports row-level access, but `sepgsql` does not.

### Covert channels

`sepgsql` does not try to hide the existence of a certain object, even if the user is not allowed to reference it. For example, we can infer the existence of an invisible object as a result of primary key conflicts, foreign key violations, and so on, even if we cannot obtain the contents of the object. The existence of a top secret table cannot be hidden; we only hope to conceal its contents.

### [Fedora SELinux FAQ](#)

This document answers frequently asked questions about SELinux. It focuses primarily on Fedora, but is not limited to Fedora.

## F.50.9. Author

KaiGai Kohei <kaigai@ak.jp.nec.com>

## F.51. shared\_ispell

The `shared_ispell` module provides a shared ispell dictionary, i.e. a dictionary that's stored in shared segment. The traditional ispell implementation means that each session initializes and stores the dictionary on it's own, which means a lot of CPU/RAM is wasted.

This extension allocates an area in shared segment (you have to choose the size in advance) and then loads the dictionary into it when it's used for the first time.

### F.51.1. Functions

The functions provided by the `shared_ispell` module are shown in [Table F.94](#).

**Table F.94. `shared_ispell` Functions**

Function	Returns	Description
<code>shared_ispell_reset()</code>	void	Resets the dictionaries (e.g. so that you can reload the updated files from disk). The sessions that already use the dictionaries will be forced to reinitialize them.
<code>shared_ispell_mem_used()</code>	int	Returns a value of used memory of the shared segment by loaded shared dictionaries in bytes.
<code>shared_ispell_mem_available()</code>	int	Returns a value of available memory of the shared segment.
<code>shared_ispell_dicts()</code>	setof(dict_name varchar, affix_name varchar, words int, affixes int, bytes int)	Returns a list of dictionaries loaded in the shared segment.
<code>shared_ispell_stoplists()</code>	setof(stop_name varchar, words int, bytes int)	Returns a list of stopwords loaded in the shared segment.

### F.51.2. GUC Parameters

`shared_ispell.max_size` (int)

Defines the maximum size of the shared segment. This is a hard limit, the shared segment is not extensible and you need to set it so that all the dictionaries fit into it and not much memory is wasted.

### F.51.3. Using the dictionary

The module needs to allocate space in the shared memory segment. So add this to the config file (or update the current values):

```
# libraries to load
shared_preload_libraries = 'shared_ispell'
```

```
# config of the shared memory
shared_ispell.max_size = 32MB
```

To find out how much memory you actually need, use a large value (e.g. 200MB) and load all the dictionaries you want to use. Then use the `shared_ispell_mem_used()` function to find out how much memory was actually used (and set the `shared_ispell.max_size` GUC variable accordingly).

Don't set it exactly to that value, leave there some free space, so that you can reload the dictionaries without changing the GUC `max_size` limit (which requires a restart of the DB). Something like 512kB should be just fine.

The extension defines a `shared_ispell` template that you may use to define custom dictionaries. E.g. you may do this:

```
CREATE TEXT SEARCH DICTIONARY english_shared (
    TEMPLATE = shared_ispell,
    DictFile = en_us,
    AffFile = en_us,
```

```

    StopWords = english
);

CREATE TEXT SEARCH CONFIGURATION public.english_shared
    ( COPY = pg_catalog.simple );

ALTER TEXT SEARCH CONFIGURATION english_shared
    ALTER MAPPING FOR asciiword, asciihword, hword_asciipart,
        word, hword, hword_part
    WITH english_shared, english_stem;

```

We can test created configuration:

```

SELECT * FROM ts_debug('english_shared', 'abilities');
  alias  | description  | token  | dictionaries  | dictionary
  | lexemes
-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----
  asciiword | Word, all ASCII | abilities | {english_shared,english_stem} |
  english_shared | {ability}
(1 row)

```

Or you can update your own text search configuration. For example, you have the `public.english` dictionary. You can update it to use the `shared_ispell` template:

```

ALTER TEXT SEARCH CONFIGURATION public.english
    ALTER MAPPING FOR asciiword, asciihword, hword_asciipart,
        word, hword, hword_part
    WITH english_shared, english_stem;

```

## F.51.4. Author

Tomas Vondra <tomas.vondra@2ndquadrant.com>, Prague, Czech Republic

## F.52. spi

The `spi` module provides several workable examples of using the [Server Programming Interface \(SPI\)](#) and triggers. While these functions are of some value in their own right, they are even more useful as examples to modify for your own purposes. The functions are general enough to be used with any table, but you have to specify table and field names (as described below) while creating a trigger.

Each of the groups of functions described below is provided as a separately-installable extension.

### F.52.1. refint — Functions for Implementing Referential Integrity

`check_primary_key()` and `check_foreign_key()` are used to check foreign key constraints. (This functionality is long since superseded by the built-in foreign key mechanism, of course, but the module is still useful as an example.)

`check_primary_key()` checks the referencing table. To use, create a `BEFORE INSERT OR UPDATE` trigger using this function on a table referencing another table. Specify as the trigger arguments: the referencing table's column name(s) which form the foreign key, the referenced table name, and the column names in the referenced table which form the primary/unique key. To handle multiple foreign keys, create a trigger for each reference.

`check_foreign_key()` checks the referenced table. To use, create a `BEFORE DELETE OR UPDATE` trigger using this function on a table referenced by other table(s). Specify as the trigger arguments: the number of referencing tables for which the function has to perform checking, the action if a referencing key is found (`cascade` — to delete the referencing row, `restrict` — to abort transaction if referencing keys exist, `setnull` — to set referencing key fields to null), the triggered table's column names which form the primary/unique key, then the referencing table name and column names (repeated for as many

referencing tables as were specified by first argument). Note that the primary/unique key columns should be marked NOT NULL and should have a unique index.

There are examples in `refint.example`.

## F.52.2. `autoinc` — Functions for Autoincrementing Fields

`autoinc()` is a trigger that stores the next value of a sequence into an integer field. This has some overlap with the built-in “serial column” feature, but it is not the same: `autoinc()` will override attempts to substitute a different field value during inserts, and optionally it can be used to increment the field during updates, too.

To use, create a `BEFORE INSERT` (or optionally `BEFORE INSERT OR UPDATE`) trigger using this function. Specify two trigger arguments: the name of the integer column to be modified, and the name of the sequence object that will supply values. (Actually, you can specify any number of pairs of such names, if you'd like to update more than one autoincrementing column.)

There is an example in `autoinc.example`.

## F.52.3. `insert_username` — Functions for Tracking Who Changed a Table

`insert_username()` is a trigger that stores the current user's name into a text field. This can be useful for tracking who last modified a particular row within a table.

To use, create a `BEFORE INSERT` and/or `UPDATE` trigger using this function. Specify a single trigger argument: the name of the text column to be modified.

There is an example in `insert_username.example`.

## F.52.4. `moddatetime` — Functions for Tracking Last Modification Time

`moddatetime()` is a trigger that stores the current time into a `timestamp` field. This can be useful for tracking the last modification time of a particular row within a table.

To use, create a `BEFORE UPDATE` trigger using this function. Specify a single trigger argument: the name of the column to be modified. The column must be of type `timestamp` or `timestamp with time zone`.

There is an example in `moddatetime.example`.

## F.53. `sr_plan`

### Important

The `sr_plan` extension is no longer supported in Postgres Pro.

### F.53.1. Rationale

`sr_plan` is an extension which allows to save query execution plans and use these plans for all repetitions of same query, instead of optimizing identical query again and again.

`sr_plan` looks like Oracle Outline system. It can be used to lock the execution plan. It is necessary if you do not trust the planner or able to form a better plan.

Typically, DBA would play with queries interactively, and save their plans and then enable use of saved plans for the queries, where predictable response time is essential.

Then application which uses these queries would use saved plans.

```
=>create table test_table (a numeric, b text);
CREATE TABLE
=>insert into test_table values (1,'1'),(2,'2'),(3,'3');
INSERT 0 3
=> set sr_plan.write_mode = true;
SET
=> select a,b from test_table where a = _p(1);
 a | b
---+---
 1 | 1
(1 row)

=> set sr_plan.write_mode = false;
SET
```

Now plan for query from our table is saved with parameter. So, if we enable saved plan in this table, this plan would be used for query with any value for a, as long as this value is wrapped with `_p()` function.

```
=>update sr_plans set enable = true where query=
 'select a,b from test_table where a = _p(1)';
UPDATE 1
-- These queries would use saved plan

=>select a,b from test_table where a = _p(2);
 a | b
---+---
 2 | 2
(1 row)

=>select a,b from test_table where a = _p(3);
 a | b
---+---
 3 | 3
(1 row)

-- This query wouldn't use saved plan, because constant is not wrapped
-- with _p()

=>select a,b from test_table where a = 1;
 a | b
---+---
 1 | 1
(1 row)
```

## F.54. sslinfo

The `sslinfo` module provides information about the SSL certificate that the current client provided when connecting to Postgres Pro. The module is useless (most functions will return NULL) if the current connection does not use SSL.

Some of the information available through this module can also be obtained using the built-in system view `pg_stat_ssl`.

This extension won't build at all unless the installation was configured with `--with-openssl`.

### F.54.1. Functions Provided

`ssl_is_used()` returns boolean

Returns true if current connection to server uses SSL, and false otherwise.

`ssl_version()` returns text

Returns the name of the protocol used for the SSL connection (e.g., TLSv1.0, TLSv1.1, or TLSv1.2).

`ssl_cipher()` returns text

Returns the name of the cipher used for the SSL connection (e.g., DHE-RSA-AES256-SHA).

`ssl_client_cert_present()` returns boolean

Returns true if current client has presented a valid SSL client certificate to the server, and false otherwise. (The server might or might not be configured to require a client certificate.)

`ssl_client_serial()` returns numeric

Returns serial number of current client certificate. The combination of certificate serial number and certificate issuer is guaranteed to uniquely identify a certificate (but not its owner — the owner ought to regularly change their keys, and get new certificates from the issuer).

So, if you run your own CA and allow only certificates from this CA to be accepted by the server, the serial number is the most reliable (albeit not very mnemonic) means to identify a user.

`ssl_client_dn()` returns text

Returns the full subject of the current client certificate, converting character data into the current database encoding. It is assumed that if you use non-ASCII characters in the certificate names, your database is able to represent these characters, too. If your database uses the SQL\_ASCII encoding, non-ASCII characters in the name will be represented as UTF-8 sequences.

The result looks like `/CN=Somebody /C=Some country/O=Some organization`.

`ssl_issuer_dn()` returns text

Returns the full issuer name of the current client certificate, converting character data into the current database encoding. Encoding conversions are handled the same as for `ssl_client_dn`.

The combination of the return value of this function with the certificate serial number uniquely identifies the certificate.

This function is really useful only if you have more than one trusted CA certificate in your server's certificate authority file, or if this CA has issued some intermediate certificate authority certificates.

`ssl_client_dn_field(fieldname text)` returns text

This function returns the value of the specified field in the certificate subject, or NULL if the field is not present. Field names are string constants that are converted into ASN1 object identifiers using the OpenSSL object database. The following values are acceptable:

```
commonName (alias CN)
surname (alias SN)
name
givenName (alias GN)
countryName (alias C)
localityName (alias L)
stateOrProvinceName (alias ST)
organizationName (alias O)
organizationalUnitName (alias OU)
title
description
initials
postalCode
streetAddress
generationQualifier
description
```

dnQualifier  
x500UniqueIdentifier  
pseudonym  
role  
emailAddress

All of these fields are optional, except `commonName`. It depends entirely on your CA's policy which of them would be included and which wouldn't. The meaning of these fields, however, is strictly defined by the X.500 and X.509 standards, so you cannot just assign arbitrary meaning to them.

`ssl_issuer_field(fieldname text)` returns `text`

Same as `ssl_client_dn_field`, but for the certificate issuer rather than the certificate subject.

`ssl_extension_info()` returns `setof record`

Provide information about extensions of client certificate: extension name, extension value, and if it is a critical extension.

## F.55. tablefunc

The `tablefunc` module includes various functions that return tables (that is, multiple rows). These functions are useful both in their own right and as examples of how to write C functions that return multiple rows.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.55.1. Functions Provided

[Table F.95](#) summarizes the functions provided by the `tablefunc` module.

**Table F.95. tablefunc Functions**

Function	Description
<code>normal_rand ( numvals integer, mean float8, stddev float8 )</code>	<code>→ setof float8</code> Produces a set of normally distributed random values.
<code>crosstab ( sql text )</code>	<code>→ setof record</code> Produces a “pivot table” containing row names plus <i>N</i> value columns, where <i>N</i> is determined by the row type specified in the calling query.
<code>crosstabN ( sql text )</code>	<code>→ setof table_crosstab_ N</code> Produces a “pivot table” containing row names plus <i>N</i> value columns. <code>crosstab2</code> , <code>crosstab3</code> , and <code>crosstab4</code> are predefined, but you can create additional <code>crosstabN</code> functions as described below.
<code>crosstab ( source_sql text, category_sql text )</code>	<code>→ setof record</code> Produces a “pivot table” with the value columns specified by a second query.
<code>crosstab ( sql text, N integer )</code>	<code>→ setof record</code> Obsolete version of <code>crosstab(text)</code> . The parameter <i>N</i> is now ignored, since the number of value columns is always determined by the calling query.

Function	Description
<code>connectby ( relname text, keyid_fld text, parent_keyid_fld text [, orderby_fld text ], start_with text, max_depth integer [, branch_delim text ] )</code>	<code>→ setof record</code> Produces a representation of a hierarchical tree structure.

### F.55.1.1. normal\_rand

`normal_rand(int numvals, float8 mean, float8 stddev)` returns `setof float8`  
`normal_rand` produces a set of normally distributed random values (Gaussian distribution).

*numvals* is the number of values to be returned from the function. *mean* is the mean of the normal distribution of values and *stddev* is the standard deviation of the normal distribution of values.

For example, this call requests 1000 values with a mean of 5 and a standard deviation of 3:

```
test=# SELECT * FROM normal_rand(1000, 5, 3);
      normal_rand
-----
 1.56556322244898
 9.10040991424657
 5.36957140345079
-0.369151492880995
 0.283600703686639
 .
 .
 .
 4.82992125404908
 9.71308014517282
 2.49639286969028
(1000 rows)
```

### F.55.1.2. crosstab(text)

`crosstab(text sql)`  
`crosstab(text sql, int N)`

The `crosstab` function is used to produce “pivot” displays, wherein data is listed across the page rather than down. For example, we might have data like

```
row1  val11
row1  val12
row1  val13
...
row2  val21
row2  val22
row2  val23
...
```

which we wish to display like

```
row1  val11  val12  val13  ...
row2  val21  val22  val23  ...
...
```

The `crosstab` function takes a text parameter that is a SQL query producing raw data formatted in the first way, and produces a table formatted in the second way.

The *sql* parameter is a SQL statement that produces the source set of data. This statement must return one `row_name` column, one `category` column, and one `value` column. *N* is an obsolete parameter, ignored if supplied (formerly this had to match the number of output value columns, but now that is determined by the calling query).

For example, the provided query might produce a set something like:

row_name	cat	value
row1	cat1	val1
row1	cat2	val2
row1	cat3	val3
row1	cat4	val4
row2	cat1	val5
row2	cat2	val6
row2	cat3	val7
row2	cat4	val8

The `crosstab` function is declared to return `setof record`, so the actual names and types of the output columns must be defined in the `FROM` clause of the calling `SELECT` statement, for example:

```
SELECT * FROM crosstab('...') AS ct(row_name text, category_1 text, category_2 text);
```

This example produces a set something like:

row_name	category_1	category_2
row1	val1	val2
row2	val5	val6

The `FROM` clause must define the output as one `row_name` column (of the same data type as the first result column of the SQL query) followed by `N` `value` columns (all of the same data type as the third result column of the SQL query). You can set up as many output value columns as you wish. The names of the output columns are up to you.

The `crosstab` function produces one output row for each consecutive group of input rows with the same `row_name` value. It fills the output `value` columns, left to right, with the `value` fields from these rows. If there are fewer rows in a group than there are output `value` columns, the extra output columns are filled with nulls; if there are more rows, the extra input rows are skipped.

In practice the SQL query should always specify `ORDER BY 1, 2` to ensure that the input rows are properly ordered, that is, values with the same `row_name` are brought together and correctly ordered within the row. Notice that `crosstab` itself does not pay any attention to the second column of the query result; it's just there to be ordered by, to control the order in which the third-column values appear across the page.

Here is a complete example:

```
CREATE TABLE ct(id SERIAL, rowid TEXT, attribute TEXT, value TEXT);
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att1','val1');
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att2','val2');
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att3','val3');
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att4','val4');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att1','val5');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att2','val6');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att3','val7');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att4','val8');

SELECT *
FROM crosstab(
  'select rowid, attribute, value
   from ct
   where attribute = 'att2' or attribute = 'att3'
   order by 1,2')
AS ct(row_name text, category_1 text, category_2 text, category_3 text);
```

```

row_name | category_1 | category_2 | category_3
-----+-----+-----+-----
test1    | val2       | val3       |
test2    | val6       | val7       |
(2 rows)

```

You can avoid always having to write out a `FROM` clause to define the output columns, by setting up a custom `crostab` function that has the desired output row type wired into its definition. This is described in the next section. Another possibility is to embed the required `FROM` clause in a view definition.

### Note

See also the `\crostabview` command in `psql`, which provides functionality similar to `crostab()`.

#### F.55.1.3. `crostabN(text)`

```
crostabN(text sql)
```

The `crostabN` functions are examples of how to set up custom wrappers for the general `crostab` function, so that you need not write out column names and types in the calling `SELECT` query. The `tablefunc` module includes `crostab2`, `crostab3`, and `crostab4`, whose output row types are defined as

```

CREATE TYPE tablefunc_crostab_N AS (
    row_name TEXT,
    category_1 TEXT,
    category_2 TEXT,
    .
    .
    .
    category_N TEXT
);

```

Thus, these functions can be used directly when the input query produces `row_name` and `value` columns of type `text`, and you want 2, 3, or 4 output values columns. In all other ways they behave exactly as described above for the general `crostab` function.

For instance, the example given in the previous section would also work as

```

SELECT *
FROM crostab3(
    'select rowid, attribute, value
    from ct
    where attribute = 'att2' or attribute = 'att3'
    order by 1,2');

```

These functions are provided mostly for illustration purposes. You can create your own return types and functions based on the underlying `crostab()` function. There are two ways to do it:

- Create a composite type describing the desired output columns, similar to the examples in `contrib/tablefunc/tablefunc--1.0.sql`. Then define a unique function name accepting one `text` parameter and returning `setof your_type_name`, but linking to the same underlying `crostab C` function. For example, if your source data produces row names that are `text`, and values that are `float8`, and you want 5 value columns:

```

CREATE TYPE my_crostab_float8_5_cols AS (
    my_row_name text,
    my_category_1 float8,
    my_category_2 float8,
    my_category_3 float8,

```

```

    my_category_4 float8,
    my_category_5 float8
);

CREATE OR REPLACE FUNCTION crosstab_float8_5_cols(text)
    RETURNS setof my_crosstab_float8_5_cols
    AS '$libdir/tablefunc','crosstab' LANGUAGE C STABLE STRICT;

```

- Use OUT parameters to define the return type implicitly. The same example could also be done this way:

```

CREATE OR REPLACE FUNCTION crosstab_float8_5_cols(
    IN text,
    OUT my_row_name text,
    OUT my_category_1 float8,
    OUT my_category_2 float8,
    OUT my_category_3 float8,
    OUT my_category_4 float8,
    OUT my_category_5 float8)
    RETURNS setof record
    AS '$libdir/tablefunc','crosstab' LANGUAGE C STABLE STRICT;

```

#### F.55.1.4. crosstab(text, text)

`crosstab(text source_sql, text category_sql)`

The main limitation of the single-parameter form of `crosstab` is that it treats all values in a group alike, inserting each value into the first available column. If you want the value columns to correspond to specific categories of data, and some groups might not have data for some of the categories, that doesn't work well. The two-parameter form of `crosstab` handles this case by providing an explicit list of the categories corresponding to the output columns.

`source_sql` is a SQL statement that produces the source set of data. This statement must return one `row_name` column, one `category` column, and one `value` column. It may also have one or more “extra” columns. The `row_name` column must be first. The `category` and `value` columns must be the last two columns, in that order. Any columns between `row_name` and `category` are treated as “extra”. The “extra” columns are expected to be the same for all rows with the same `row_name` value.

For example, `source_sql` might produce a set something like:

```
SELECT row_name, extra_col, cat, value FROM foo ORDER BY 1;
```

row_name	extra_col	cat	value
row1	extra1	cat1	val1
row1	extra1	cat2	val2
row1	extra1	cat4	val4
row2	extra2	cat1	val5
row2	extra2	cat2	val6
row2	extra2	cat3	val7
row2	extra2	cat4	val8

`category_sql` is a SQL statement that produces the set of categories. This statement must return only one column. It must produce at least one row, or an error will be generated. Also, it must not produce duplicate values, or an error will be generated. `category_sql` might be something like:

```
SELECT DISTINCT cat FROM foo ORDER BY 1;
   cat
-----
  cat1
  cat2
  cat3
```

cat4

The `crosstab` function is declared to return `setof record`, so the actual names and types of the output columns must be defined in the `FROM` clause of the calling `SELECT` statement, for example:

```
SELECT * FROM crosstab('...', '...')
  AS ct(row_name text, extra text, cat1 text, cat2 text, cat3 text, cat4 text);
```

This will produce a result something like:

	<== value columns ==>				
row_name	extra	cat1	cat2	cat3	cat4
row1	extra1	val1	val2		val4
row2	extra2	val5	val6	val7	val8

The `FROM` clause must define the proper number of output columns of the proper data types. If there are  $N$  columns in the `source_sql` query's result, the first  $N-2$  of them must match up with the first  $N-2$  output columns. The remaining output columns must have the type of the last column of the `source_sql` query's result, and there must be exactly as many of them as there are rows in the `category_sql` query's result.

The `crosstab` function produces one output row for each consecutive group of input rows with the same `row_name` value. The output `row_name` column, plus any "extra" columns, are copied from the first row of the group. The output `value` columns are filled with the `value` fields from rows having matching `category` values. If a row's `category` does not match any output of the `category_sql` query, its value is ignored. Output columns whose matching category is not present in any input row of the group are filled with nulls.

In practice the `source_sql` query should always specify `ORDER BY 1` to ensure that values with the same `row_name` are brought together. However, ordering of the categories within a group is not important. Also, it is essential to be sure that the order of the `category_sql` query's output matches the specified output column order.

Here are two complete examples:

```
create table sales(year int, month int, qty int);
insert into sales values(2007, 1, 1000);
insert into sales values(2007, 2, 1500);
insert into sales values(2007, 7, 500);
insert into sales values(2007, 11, 1500);
insert into sales values(2007, 12, 2000);
insert into sales values(2008, 1, 1000);

select * from crosstab(
  'select year, month, qty from sales order by 1',
  'select m from generate_series(1,12) m'
) as (
  year int,
  "Jan" int,
  "Feb" int,
  "Mar" int,
  "Apr" int,
  "May" int,
  "Jun" int,
  "Jul" int,
  "Aug" int,
  "Sep" int,
  "Oct" int,
  "Nov" int,
  "Dec" int
```

```
);
year | Jan | Feb | Mar | Apr | May | Jun | Jul | Aug | Sep | Oct | Nov | Dec
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----
2007 | 1000 | 1500 |      |      |      |      | 500 |      |      |      | 1500 | 2000
2008 | 1000 |      |      |      |      |      |      |      |      |      |      |      |
(2 rows)

CREATE TABLE cth(rowid text, rowdt timestamp, attribute text, val text);
INSERT INTO cth VALUES('test1','01 March 2003','temperature','42');
INSERT INTO cth VALUES('test1','01 March 2003','test_result','PASS');
INSERT INTO cth VALUES('test1','01 March 2003','volts','2.6987');
INSERT INTO cth VALUES('test2','02 March 2003','temperature','53');
INSERT INTO cth VALUES('test2','02 March 2003','test_result','FAIL');
INSERT INTO cth VALUES('test2','02 March 2003','test_startdate','01 March 2003');
INSERT INTO cth VALUES('test2','02 March 2003','volts','3.1234');

SELECT * FROM crosstab
(
  'SELECT rowid, rowdt, attribute, val FROM cth ORDER BY 1',
  'SELECT DISTINCT attribute FROM cth ORDER BY 1'
)
AS
(
  rowid text,
  rowdt timestamp,
  temperature int4,
  test_result text,
  test_startdate timestamp,
  volts float8
);
rowid |          rowdt          | temperature | test_result |          test_startdate
| volts
-----+-----+-----+-----+-----
test1 | Sat Mar 01 00:00:00 2003 |          42 | PASS        |
| 2.6987
test2 | Sun Mar 02 00:00:00 2003 |          53 | FAIL        | Sat Mar 01 00:00:00
2003 | 3.1234
(2 rows)
```

You can create predefined functions to avoid having to write out the result column names and types in each query. See the examples in the previous section. The underlying C function for this form of `crosstab` is named `crosstab_hash`.

### F.55.1.5. connectby

```
connectby(text relname, text keyid_fld, text parent_keyid_fld
          [, text orderby_fld ], text start_with, int max_depth
          [, text branch_delim ])
```

The `connectby` function produces a display of hierarchical data that is stored in a table. The table must have a key field that uniquely identifies rows, and a parent-key field that references the parent (if any) of each row. `connectby` can display the sub-tree descending from any row.

Table F.96 explains the parameters.

**Table F.96. connectby Parameters**

Parameter	Description
<i>relname</i>	Name of the source relation

Parameter	Description
<i>keyid_fld</i>	Name of the key field
<i>parent_keyid_fld</i>	Name of the parent-key field
<i>orderby_fld</i>	Name of the field to order siblings by (optional)
<i>start_with</i>	Key value of the row to start at
<i>max_depth</i>	Maximum depth to descend to, or zero for unlimited depth
<i>branch_delim</i>	String to separate keys with in branch output (optional)

The key and parent-key fields can be any data type, but they must be the same type. Note that the *start\_with* value must be entered as a text string, regardless of the type of the key field.

The `connectby` function is declared to return `setof record`, so the actual names and types of the output columns must be defined in the `FROM` clause of the calling `SELECT` statement, for example:

```
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'pos', 'row2', 0,
 '~')
  AS t(keyid text, parent_keyid text, level int, branch text, pos int);
```

The first two output columns are used for the current row's key and its parent row's key; they must match the type of the table's key field. The third output column is the depth in the tree and must be of type `integer`. If a *branch\_delim* parameter was given, the next output column is the branch display and must be of type `text`. Finally, if an *orderby\_fld* parameter was given, the last output column is a serial number, and must be of type `integer`.

The "branch" output column shows the path of keys taken to reach the current row. The keys are separated by the specified *branch\_delim* string. If no branch display is wanted, omit both the *branch\_delim* parameter and the branch column in the output column list.

If the ordering of siblings of the same parent is important, include the *orderby\_fld* parameter to specify which field to order siblings by. This field can be of any sortable data type. The output column list must include a final integer serial-number column, if and only if *orderby\_fld* is specified.

The parameters representing table and field names are copied as-is into the SQL queries that `connectby` generates internally. Therefore, include double quotes if the names are mixed-case or contain special characters. You may also need to schema-qualify the table name.

In large tables, performance will be poor unless there is an index on the parent-key field.

It is important that the *branch\_delim* string not appear in any key values, else `connectby` may incorrectly report an infinite-recursion error. Note that if *branch\_delim* is not provided, a default value of `~` is used for recursion detection purposes.

Here is an example:

```
CREATE TABLE connectby_tree(keyid text, parent_keyid text, pos int);

INSERT INTO connectby_tree VALUES('row1',NULL, 0);
INSERT INTO connectby_tree VALUES('row2','row1', 0);
INSERT INTO connectby_tree VALUES('row3','row1', 0);
INSERT INTO connectby_tree VALUES('row4','row2', 1);
INSERT INTO connectby_tree VALUES('row5','row2', 0);
INSERT INTO connectby_tree VALUES('row6','row4', 0);
INSERT INTO connectby_tree VALUES('row7','row3', 0);
INSERT INTO connectby_tree VALUES('row8','row6', 0);
INSERT INTO connectby_tree VALUES('row9','row5', 0);
```

```
-- with branch, without orderby_fld (order of results is not guaranteed)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'row2', 0, '~')
AS t(keyid text, parent_keyid text, level int, branch text);
keyid | parent_keyid | level |      branch
-----+-----+-----+-----
row2  |              |      0 | row2
row4  | row2         |      1 | row2~row4
row6  | row4         |      2 | row2~row4~row6
row8  | row6         |      3 | row2~row4~row6~row8
row5  | row2         |      1 | row2~row5
row9  | row5         |      2 | row2~row5~row9
(6 rows)
```

```
-- without branch, without orderby_fld (order of results is not guaranteed)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'row2', 0)
AS t(keyid text, parent_keyid text, level int);
keyid | parent_keyid | level
-----+-----+-----
row2  |              |      0
row4  | row2         |      1
row6  | row4         |      2
row8  | row6         |      3
row5  | row2         |      1
row9  | row5         |      2
(6 rows)
```

```
-- with branch, with orderby_fld (notice that row5 comes before row4)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'pos', 'row2', 0,
 '~')
AS t(keyid text, parent_keyid text, level int, branch text, pos int);
keyid | parent_keyid | level |      branch      | pos
-----+-----+-----+-----+-----
row2  |              |      0 | row2              | 1
row5  | row2         |      1 | row2~row5        | 2
row9  | row5         |      2 | row2~row5~row9   | 3
row4  | row2         |      1 | row2~row4        | 4
row6  | row4         |      2 | row2~row4~row6   | 5
row8  | row6         |      3 | row2~row4~row6~row8 | 6
(6 rows)
```

```
-- without branch, with orderby_fld (notice that row5 comes before row4)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'pos', 'row2', 0)
AS t(keyid text, parent_keyid text, level int, pos int);
keyid | parent_keyid | level | pos
-----+-----+-----+-----
row2  |              |      0 | 1
row5  | row2         |      1 | 2
row9  | row5         |      2 | 3
row4  | row2         |      1 | 4
row6  | row4         |      2 | 5
row8  | row6         |      3 | 6
(6 rows)
```

## F.55.2. Author

Joe Conway

## F.56. tcn

The `tcn` module provides a trigger function that notifies listeners of changes to any table on which it is attached. It must be used as an `AFTER` trigger `FOR EACH ROW`.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

Only one parameter may be supplied to the function in a `CREATE TRIGGER` statement, and that is optional. If supplied it will be used for the channel name for the notifications. If omitted `tcn` will be used for the channel name.

The payload of the notifications consists of the table name, a letter to indicate which type of operation was performed, and column name/value pairs for primary key columns. Each part is separated from the next by a comma. For ease of parsing using regular expressions, table and column names are always wrapped in double quotes, and data values are always wrapped in single quotes. Embedded quotes are doubled.

A brief example of using the extension follows.

```
test=# create table tcndata
test-#   (
test(#   a int not null,
test(#   b date not null,
test(#   c text,
test(#   primary key (a, b)
test(#   );
CREATE TABLE
test=# create trigger tcndata_tcn_trigger
test-#   after insert or update or delete on tcndata
test-#   for each row execute function triggered_change_notification();
CREATE TRIGGER
test=# listen tcn;
LISTEN
test=# insert into tcndata values (1, date '2012-12-22', 'one'),
test-#                               (1, date '2012-12-23', 'another'),
test-#                               (2, date '2012-12-23', 'two');
INSERT 0 3
Asynchronous notification "tcn" with payload ""tcndata",I,"a"='1',"b"='2012-12-22'"
received from server process with PID 22770.
Asynchronous notification "tcn" with payload ""tcndata",I,"a"='1',"b"='2012-12-23'"
received from server process with PID 22770.
Asynchronous notification "tcn" with payload ""tcndata",I,"a"='2',"b"='2012-12-23'"
received from server process with PID 22770.
test=# update tcndata set c = 'uno' where a = 1;
UPDATE 2
Asynchronous notification "tcn" with payload ""tcndata",U,"a"='1',"b"='2012-12-22'"
received from server process with PID 22770.
Asynchronous notification "tcn" with payload ""tcndata",U,"a"='1',"b"='2012-12-23'"
received from server process with PID 22770.
test=# delete from tcndata where a = 1 and b = date '2012-12-22';
DELETE 1
Asynchronous notification "tcn" with payload ""tcndata",D,"a"='1',"b"='2012-12-22'"
received from server process with PID 22770.
```

## F.57. test\_decoding

`test_decoding` is an example of a logical decoding output plugin. It doesn't do anything especially useful, but can serve as a starting point for developing your own output plugin.

`test_decoding` receives WAL through the logical decoding mechanism and decodes it into text representations of the operations performed.

Typical output from this plugin, used over the SQL logical decoding interface, might be:

```
postgres=# SELECT * FROM pg_logical_slot_get_changes('test_slot', NULL, NULL, 'include-
xids', '0');
 lsn      |  xid  | data
-----+-----+-----
 0/16D30F8 | 691  | BEGIN
 0/16D32A0 | 691  | table public.data: INSERT: id[int4]:2 data[text]:'arg'
 0/16D32A0 | 691  | table public.data: INSERT: id[int4]:3 data[text]:'demo'
 0/16D32A0 | 691  | COMMIT
 0/16D32D8 | 692  | BEGIN
 0/16D3398 | 692  | table public.data: DELETE: id[int4]:2
 0/16D3398 | 692  | table public.data: DELETE: id[int4]:3
 0/16D3398 | 692  | COMMIT
(8 rows)
```

## F.58. tsm\_system\_rows

The `tsm_system_rows` module provides the table sampling method `SYSTEM_ROWS`, which can be used in the `TABLESAMPLE` clause of a `SELECT` command.

This table sampling method accepts a single integer argument that is the maximum number of rows to read. The resulting sample will always contain exactly that many rows, unless the table does not contain enough rows, in which case the whole table is selected.

Like the built-in `SYSTEM` sampling method, `SYSTEM_ROWS` performs block-level sampling, so that the sample is not completely random but may be subject to clustering effects, especially if only a small number of rows are requested.

`SYSTEM_ROWS` does not support the `REPEATABLE` clause.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.58.1. Examples

Here is an example of selecting a sample of a table with `SYSTEM_ROWS`. First install the extension:

```
CREATE EXTENSION tsm_system_rows;
```

Then you can use it in a `SELECT` command, for instance:

```
SELECT * FROM my_table TABLESAMPLE SYSTEM_ROWS(100);
```

This command will return a sample of 100 rows from the table `my_table` (unless the table does not have 100 visible rows, in which case all its rows are returned).

## F.59. tsm\_system\_time

The `tsm_system_time` module provides the table sampling method `SYSTEM_TIME`, which can be used in the `TABLESAMPLE` clause of a `SELECT` command.

This table sampling method accepts a single floating-point argument that is the maximum number of milliseconds to spend reading the table. This gives you direct control over how long the query takes, at the price that the size of the sample becomes hard to predict. The resulting sample will contain as many rows as could be read in the specified time, unless the whole table has been read first.

Like the built-in `SYSTEM` sampling method, `SYSTEM_TIME` performs block-level sampling, so that the sample is not completely random but may be subject to clustering effects, especially if only a small number of rows are selected.

`SYSTEM_TIME` does not support the `REPEATABLE` clause.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

## F.59.1. Examples

Here is an example of selecting a sample of a table with `SYSTEM_TIME`. First install the extension:

```
CREATE EXTENSION tsm_system_time;
```

Then you can use it in a `SELECT` command, for instance:

```
SELECT * FROM my_table TABLESAMPLE SYSTEM_TIME(1000);
```

This command will return as large a sample of `my_table` as it can read in 1 second (1000 milliseconds). Of course, if the whole table can be read in under 1 second, all its rows will be returned.

## F.60. unaccent

`unaccent` is a text search dictionary that removes accents (diacritic signs) from lexemes. It's a filtering dictionary, which means its output is always passed to the next dictionary (if any), unlike the normal behavior of dictionaries. This allows accent-insensitive processing for full text search.

The current implementation of `unaccent` cannot be used as a normalizing dictionary for the `thesaurus` dictionary.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.60.1. Configuration

An `unaccent` dictionary accepts the following options:

- `RULES` is the base name of the file containing the list of translation rules. This file must be stored in `$$SHAREDIR/tsearch_data/` (where `$$SHAREDIR` means the Postgres Pro installation's shared-data directory). Its name must end in `.rules` (which is not to be included in the `RULES` parameter).

The rules file has the following format:

- Each line represents one translation rule, consisting of a character with accent followed by a character without accent. The first is translated into the second. For example,

À	A
Á	A
Â	A
Ã	A
Ä	A
Å	A
Æ	AE

The two characters must be separated by whitespace, and any leading or trailing whitespace on a line is ignored.

- Alternatively, if only one character is given on a line, instances of that character are deleted; this is useful in languages where accents are represented by separate characters.
- Actually, each “character” can be any string not containing whitespace, so `unaccent` dictionaries could be used for other sorts of substring substitutions besides diacritic removal.
- As with other Postgres Pro text search configuration files, the rules file must be stored in UTF-8 encoding. The data is automatically translated into the current database's encoding when loaded. Any lines containing untranslatable characters are silently ignored, so that rules files can contain rules that are not applicable in the current encoding.

A more complete example, which is directly useful for most European languages, can be found in `unaccent.rules`, which is installed in `$$SHAREDIR/tsearch_data/` when the `unaccent` module is

installed. This rules file translates characters with accents to the same characters without accents, and it also expands ligatures into the equivalent series of simple characters (for example, Æ to AE).

## F.60.2. Usage

Installing the `unaccent` extension creates a text search template `unaccent` and a dictionary `unaccent` based on it. The `unaccent` dictionary has the default parameter setting `RULES='unaccent'`, which makes it immediately usable with the standard `unaccent.rules` file. If you wish, you can alter the parameter, for example

```
mydb=# ALTER TEXT SEARCH DICTIONARY unaccent (RULES='my_rules');
```

or create new dictionaries based on the template.

To test the dictionary, you can try:

```
mydb=# select ts_lexize('unaccent','Hôtel');
 ts_lexize
-----
 {Hotel}
(1 row)
```

Here is an example showing how to insert the `unaccent` dictionary into a text search configuration:

```
mydb=# CREATE TEXT SEARCH CONFIGURATION fr ( COPY = french );
mydb=# ALTER TEXT SEARCH CONFIGURATION fr
        ALTER MAPPING FOR hword, hword_part, word
        WITH unaccent, french_stem;
mydb=# select to_tsvector('fr','Hôtels de la Mer');
 to_tsvector
-----
 'hotel':1 'mer':4
(1 row)

mydb=# select to_tsvector('fr','Hôtel de la Mer') @@ to_tsquery('fr','Hotels');
 ?column?
-----

(1 row)

mydb=# select ts_headline('fr','Hôtel de la Mer',to_tsquery('fr','Hotels'));
 ts_headline
-----
 <b>Hôtel</b> de la Mer
(1 row)
```

## F.60.3. Functions

The `unaccent()` function removes accents (diacritic signs) from a given string. Basically, it's a wrapper around `unaccent`-type dictionaries, but it can be used outside normal text search contexts.

`unaccent([dictionary regdictionary, ] string text)` returns `text`

If the `dictionary` argument is omitted, the text search dictionary named `unaccent` and appearing in the same schema as the `unaccent()` function itself is used.

For example:

```
SELECT unaccent('unaccent', 'Hôtel');
SELECT unaccent('Hôtel');
```

## F.61. uuid-oss

The `uuid-osp` module provides functions to generate universally unique identifiers (UUIDs) using one of several standard algorithms. There are also functions to produce certain special UUID constants. This module is only necessary for special requirements beyond what is available in core PostgreSQL. See [Section 9.14](#) for built-in ways to generate UUIDs.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.61.1. `uuid-osp` Functions

[Table F.97](#) shows the functions available to generate UUIDs. The relevant standards ITU-T Rec. X.667, ISO/IEC 9834-8:2005, and RFC 4122 specify four algorithms for generating UUIDs, identified by the version numbers 1, 3, 4, and 5. (There is no version 2 algorithm.) Each of these algorithms could be suitable for a different set of applications.

**Table F.97. Functions for UUID Generation**

Function	Description
<code>uuid_generate_v1 () → uuid</code>	Generates a version 1 UUID. This involves the MAC address of the computer and a time stamp. Note that UUIDs of this kind reveal the identity of the computer that created the identifier and the time at which it did so, which might make it unsuitable for certain security-sensitive applications.
<code>uuid_generate_v1mc () → uuid</code>	Generates a version 1 UUID, but uses a random multicast MAC address instead of the real MAC address of the computer.
<code>uuid_generate_v3 ( namespace uuid, name text ) → uuid</code>	Generates a version 3 UUID in the given namespace using the specified input name. The namespace should be one of the special constants produced by the <code>uuid_ns_*</code> functions shown in <a href="#">Table F.98</a> . (It could be any UUID in theory.) The name is an identifier in the selected namespace. For example: <pre>SELECT uuid_generate_v3(uuid_ns_url(), 'http://www.postgresql.org');</pre> The name parameter will be MD5-hashed, so the cleartext cannot be derived from the generated UUID. The generation of UUIDs by this method has no random or environment-dependent element and is therefore reproducible.
<code>uuid_generate_v4 () → uuid</code>	Generates a version 4 UUID, which is derived entirely from random numbers.
<code>uuid_generate_v5 ( namespace uuid, name text ) → uuid</code>	Generates a version 5 UUID, which works like a version 3 UUID except that SHA-1 is used as a hashing method. Version 5 should be preferred over version 3 because SHA-1 is thought to be more secure than MD5.

**Table F.98. Functions Returning UUID Constants**

Function	Description
<code>uuid_nil () → uuid</code>	Returns a “nil” UUID constant, which does not occur as a real UUID.
<code>uuid_ns_dns () → uuid</code>	Returns a constant designating the DNS namespace for UUIDs.
<code>uuid_ns_url () → uuid</code>	

Function	Description
	Returns a constant designating the URL namespace for UUIDs.
<code>uuid_ns_oid () → uuid</code>	Returns a constant designating the ISO object identifier (OID) namespace for UUIDs. (This pertains to ASN.1 OIDs, which are unrelated to the OIDs used in Postgres Pro.)
<code>uuid_ns_x500 () → uuid</code>	Returns a constant designating the X.500 distinguished name (DN) namespace for UUIDs.

## F.61.2. Building `uuid-oss`

Historically this module depended on the OSSP UUID library, which accounts for the module's name. While the OSSP UUID library can still be found at <http://www.oss.org/pkg/lib/uuid/>, it is not well maintained, and is becoming increasingly difficult to port to newer platforms. `uuid-oss` can now be built without the OSSP library on some platforms. On FreeBSD, NetBSD, and some other BSD-derived platforms, suitable UUID creation functions are included in the core `libc` library. On Linux, macOS, and some other platforms, suitable functions are provided in the `libuuid` library, which originally came from the `e2fsprogs` project (though on modern Linux it is considered part of `util-linux-ng`). When invoking `configure`, specify `--with-uuid=bsd` to use the BSD functions, or `--with-uuid=e2fs` to use `e2fsprogs'` `libuuid`, or `--with-uuid=oss` to use the OSSP UUID library. More than one of these libraries might be available on a particular machine, so `configure` does not automatically choose one.

## F.61.3. Author

Peter Eisentraut <[peter\\_e@gmx.net](mailto:peter_e@gmx.net)>

## F.62. `xml2`

The `xml2` module provides XPath querying and XSLT functionality.

### F.62.1. Deprecation Notice

From PostgreSQL 8.3 on, there is XML-related functionality based on the SQL/XML standard in the core server. That functionality covers XML syntax checking and XPath queries, which is what this module does, and more, but the API is not at all compatible. It is planned that this module will be removed in a future version of Postgres Pro in favor of the newer standard API, so you are encouraged to try converting your applications. If you find that some of the functionality of this module is not available in an adequate form with the newer API, please explain your issue to <[pgsql-hackers@lists.postgresql.org](mailto:pgsql-hackers@lists.postgresql.org)> so that the deficiency can be addressed.

### F.62.2. Description of Functions

[Table F.99](#) shows the functions provided by this module. These functions provide straightforward XML parsing and XPath queries.

**Table F.99. `xml2` Functions**

Function	Description
<code>xml_valid ( document text ) → boolean</code>	Parses the given document and returns true if the document is well-formed XML. (Note: this is an alias for the standard Postgres Pro function <code>xml_is_well_formed()</code> . The name <code>xml_valid()</code> is technically incorrect since validity and well-formedness have different meanings in XML.)
<code>xpath_string ( document text, query text ) → text</code>	Evaluates the XPath query on the supplied document, and casts the result to <code>text</code> .

Function	Description
<code>xpath_number ( document text, query text )</code>	<code>→ real</code> Evaluates the XPath query on the supplied document, and casts the result to <code>real</code> .
<code>xpath_bool ( document text, query text )</code>	<code>→ boolean</code> Evaluates the XPath query on the supplied document, and casts the result to <code>boolean</code> .
<code>xpath_nodeSet ( document text, query text, toptag text, itemtag text )</code>	<code>→ text</code> Evaluates the query on the document and wraps the result in XML tags. If the result is multivalued, the output will look like:  <pre>&lt;toptag&gt; &lt;itemtag&gt;Value 1 which could be an XML fragment&lt;/itemtag&gt; &lt;itemtag&gt;Value 2....&lt;/itemtag&gt; &lt;/toptag&gt;</pre> <p>If either <code>toptag</code> or <code>itemtag</code> is an empty string, the relevant tag is omitted.</p>
<code>xpath_nodeSet ( document text, query text, itemtag text )</code>	<code>→ text</code> Like <code>xpath_nodeSet (document, query, toptag, itemtag)</code> but result omits <code>toptag</code> .
<code>xpath_nodeSet ( document text, query text )</code>	<code>→ text</code> Like <code>xpath_nodeSet (document, query, toptag, itemtag)</code> but result omits both tags.
<code>xpath_list ( document text, query text, separator text )</code>	<code>→ text</code> Evaluates the query on the document and returns multiple values separated by the specified separator, for example <code>Value 1, Value 2, Value 3</code> if <code>separator</code> is <code>, .</code>
<code>xpath_list ( document text, query text )</code>	<code>→ text</code> This is a wrapper for the above function that uses <code>,</code> as the separator.

### F.62.3. xpath\_table

`xpath_table (text key, text document, text relation, text xpaths, text criteria)` returns `setof record`

`xpath_table` is a table function that evaluates a set of XPath queries on each of a set of documents and returns the results as a table. The primary key field from the original document table is returned as the first column of the result so that the result set can readily be used in joins. The parameters are described in [Table F.100](#).

**Table F.100. xpath\_table Parameters**

Parameter	Description
<code>key</code>	the name of the “key” field — this is just a field to be used as the first column of the output table, i.e., it identifies the record from which each output row came (see note below about multiple values)
<code>document</code>	the name of the field containing the XML document
<code>relation</code>	the name of the table or view containing the documents
<code>xpaths</code>	one or more XPath expressions, separated by <code> </code>
<code>criteria</code>	the contents of the WHERE clause. This cannot be omitted, so use <code>true</code> or <code>1=1</code> if you want to process all the rows in the relation

These parameters (except the XPath strings) are just substituted into a plain SQL SELECT statement, so you have some flexibility — the statement is

```
SELECT <key>, <document> FROM <relation> WHERE <criteria>
```

so those parameters can be *anything* valid in those particular locations. The result from this SELECT needs to return exactly two columns (which it will unless you try to list multiple fields for key or document). Beware that this simplistic approach requires that you validate any user-supplied values to avoid SQL injection attacks.

The function has to be used in a FROM expression, with an AS clause to specify the output columns; for example

```
SELECT * FROM
xpath_table('article_id',
            'article_xml',
            'articles',
            '/article/author|/article/pages|/article/title',
            'date_entered > '2003-01-01' ')
AS t(article_id integer, author text, page_count integer, title text);
```

The AS clause defines the names and types of the columns in the output table. The first is the “key” field and the rest correspond to the XPath queries. If there are more XPath queries than result columns, the extra queries will be ignored. If there are more result columns than XPath queries, the extra columns will be NULL.

Notice that this example defines the `page_count` result column as an integer. The function deals internally with string representations, so when you say you want an integer in the output, it will take the string representation of the XPath result and use Postgres Pro input functions to transform it into an integer (or whatever type the AS clause requests). An error will result if it can't do this — for example if the result is empty — so you may wish to just stick to `text` as the column type if you think your data has any problems.

The calling SELECT statement doesn't necessarily have to be just `SELECT *` — it can reference the output columns by name or join them to other tables. The function produces a virtual table with which you can perform any operation you wish (e.g., aggregation, joining, sorting etc). So we could also have:

```
SELECT t.title, p.fullname, p.email
FROM xpath_table('article_id', 'article_xml', 'articles',
                '/article/title|/article/author/@id',
                'xpath_string(article_xml, '/article/@date') > '2003-03-20' ')
    AS t(article_id integer, title text, author_id integer),
tblPeopleInfo AS p
WHERE t.author_id = p.person_id;
```

as a more complicated example. Of course, you could wrap all of this in a view for convenience.

### F.62.3.1. Multivalued Results

The `xpath_table` function assumes that the results of each XPath query might be multivalued, so the number of rows returned by the function may not be the same as the number of input documents. The first row returned contains the first result from each query, the second row the second result from each query. If one of the queries has fewer values than the others, null values will be returned instead.

In some cases, a user will know that a given XPath query will return only a single result (perhaps a unique document identifier) — if used alongside an XPath query returning multiple results, the single-valued result will appear only on the first row of the result. The solution to this is to use the key field as part of a join against a simpler XPath query. As an example:

```
CREATE TABLE test (
    id int PRIMARY KEY,
    xml text
);

INSERT INTO test VALUES (1, '<doc num="C1">
<line num="L1"><a>1</a><b>2</b><c>3</c></line>
<line num="L2"><a>11</a><b>22</b><c>33</c></line>
```

```
</doc>');
```

```
INSERT INTO test VALUES (2, '<doc num="C2">
<line num="L1"><a>111</a><b>222</b><c>333</c></line>
<line num="L2"><a>111</a><b>222</b><c>333</c></line>
</doc>');
```

```
SELECT * FROM
  xpath_table('id','xml','test',
              '/doc/@num|/doc/line/@num|/doc/line/a|/doc/line/b|/doc/line/c',
              'true')
  AS t(id int, doc_num varchar(10), line_num varchar(10), val1 int, val2 int, val3 int)
WHERE id = 1 ORDER BY doc_num, line_num
```

id	doc_num	line_num	val1	val2	val3
1	C1	L1	1	2	3
1		L2	11	22	33

To get doc\_num on every line, the solution is to use two invocations of xpath\_table and join the results:

```
SELECT t.*,i.doc_num FROM
  xpath_table('id', 'xml', 'test',
              '/doc/line/@num|/doc/line/a|/doc/line/b|/doc/line/c',
              'true')
  AS t(id int, line_num varchar(10), val1 int, val2 int, val3 int),
  xpath_table('id', 'xml', 'test', '/doc/@num', 'true')
  AS i(id int, doc_num varchar(10))
WHERE i.id=t.id AND i.id=1
ORDER BY doc_num, line_num;
```

id	line_num	val1	val2	val3	doc_num
1	L1	1	2	3	C1
1	L2	11	22	33	C1

(2 rows)

## F.62.4. XSLT Functions

The following functions are available if libxslt is installed:

### F.62.4.1. xslt\_process

xslt\_process(text document, text stylesheet, text paramlist) returns text

This function applies the XSL stylesheet to the document and returns the transformed result. The paramlist is a list of parameter assignments to be used in the transformation, specified in the form a=1,b=2. Note that the parameter parsing is very simple-minded: parameter values cannot contain commas!

There is also a two-parameter version of xslt\_process which does not pass any parameters to the transformation.

### F.62.5. Author

John Gray <jgray@azuli.co.uk>

Development of this module was sponsored by Torchbox Ltd. (www.torchbox.com). It has the same BSD license as Postgres Pro.

---

# Appendix G. Additional Supplied Programs

This appendix and the previous one contain information regarding additional modules available in the Postgres Pro Standard distribution. See [Appendix F](#) for more information about the server extensions and plug-ins.

This appendix covers the utility programs. Once installed, they are found in the `bin` directory of the Postgres Pro Standard installation and can be used like any other program.

## G.1. Client Applications

This section covers Postgres Pro Standard client applications. They can be run from anywhere, independent of where the database server resides. See also [Postgres Pro Client Applications](#) for information about client applications that are part of the core Postgres Pro Standard distribution.

## oid2name

oid2name — resolve OIDs and file nodes in a Postgres Pro data directory

### Synopsis

```
oid2name [option...]
```

### Description

oid2name is a utility program that helps administrators to examine the file structure used by Postgres Pro. To make use of it, you need to be familiar with the database file structure, which is described in [Chapter 65](#).

#### Note

The name “oid2name” is historical, and is actually rather misleading, since most of the time when you use it, you will really be concerned with tables' filenode numbers (which are the file names visible in the database directories). Be sure you understand the difference between table OIDs and table filenodes!

oid2name connects to a target database and extracts OID, filenode, and/or table name information. You can also have it show database OIDs or tablespace OIDs.

### Options

oid2name accepts the following command-line arguments:

```
-f filenode
```

```
--filenode=filenode
```

show info for table with filenode *filenode*.

```
-i
```

```
--indexes
```

include indexes and sequences in the listing.

```
-o oid
```

```
--oid=oid
```

show info for table with OID *oid*.

```
-q
```

```
--quiet
```

omit headers (useful for scripting).

```
-s
```

```
--tablespaces
```

show tablespace OIDs.

```
-S
```

```
--system-objects
```

include system objects (those in `information_schema`, `pg_toast` and `pg_catalog` schemas).

```
-t tablename_pattern
```

```
--table=tablename_pattern
```

show info for table(s) matching *tablename\_pattern*.

`-V`  
`--version`  
Print the oid2name version and exit.

`-x`  
`--extended`  
display more information about each object shown: tablespace name, schema name, and OID.

`-?`  
`--help`  
Show help about oid2name command line arguments, and exit.

oid2name also accepts the following command-line arguments for connection parameters:

`-d database`  
`--dbname=database`  
database to connect to.

`-h host`  
`--host=host`  
database server's host.

`-H host`  
database server's host. Use of this parameter is *deprecated* as of Postgres Pro 12.

`-p port`  
`--port=port`  
database server's port.

`-U username`  
`--username=username`  
user name to connect as.

To display specific tables, select which tables to show by using `-o`, `-f` and/or `-t`. `-o` takes an OID, `-f` takes a filenode, and `-t` takes a table name (actually, it's a `LIKE` pattern, so you can use things like `foo%`). You can use as many of these options as you like, and the listing will include all objects matched by any of the options. But note that these options can only show objects in the database given by `-d`.

If you don't give any of `-o`, `-f` or `-t`, but do give `-d`, it will list all tables in the database named by `-d`. In this mode, the `-s` and `-i` options control what gets listed.

If you don't give `-d` either, it will show a listing of database OIDs. Alternatively you can give `-s` to get a tablespace listing.

## Environment

`PGHOST`  
`PGPORT`  
`PGUSER`

Default connection parameters.

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by libpq (see [Section 31.14](#)).

The environment variable `PG_COLOR` specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

**Notes**

oid2name requires a running database server with non-corrupt system catalogs. It is therefore of only limited use for recovering from catastrophic database corruption situations.

**Examples**

```
$ # what's in this database server, anyway?
```

```
$ oid2name
```

```
All databases:
```

Oid	Database Name	Tablespace
17228	alvherre	pg_default
17255	regression	pg_default
17227	template0	pg_default
1	template1	pg_default

```
$ oid2name -s
```

```
All tablespaces:
```

Oid	Tablespace Name
1663	pg_default
1664	pg_global
155151	fastdisk
155152	bigdisk

```
$ # OK, let's look into database alvherre
```

```
$ cd $PGDATA/base/17228
```

```
$ # get top 10 db objects in the default tablespace, ordered by size
```

```
$ ls -lS * | head -10
```

```
-rw----- 1 alvherre alvherre 136536064 sep 14 09:51 155173
-rw----- 1 alvherre alvherre 17965056 sep 14 09:51 1155291
-rw----- 1 alvherre alvherre 1204224 sep 14 09:51 16717
-rw----- 1 alvherre alvherre 581632 sep 6 17:51 1255
-rw----- 1 alvherre alvherre 237568 sep 14 09:50 16674
-rw----- 1 alvherre alvherre 212992 sep 14 09:51 1249
-rw----- 1 alvherre alvherre 204800 sep 14 09:51 16684

-rw----- 1 alvherre alvherre 163840 sep 14 09:50 16699
-rw----- 1 alvherre alvherre 122880 sep 6 17:51 16751
```

```
$ # I wonder what file 155173 is ...
```

```
$ oid2name -d alvherre -f 155173
```

```
From database "alvherre":
```

Filenode	Table Name
155173	accounts

```
$ # you can ask for more than one object
```

```
$ oid2name -d alvherre -f 155173 -f 1155291
```

```
From database "alvherre":
```

Filenode	Table Name
155173	accounts
1155291	accounts_pkey

```
$ # you can mix the options, and get more details with -x
```

```
$ oid2name -d alvherre -t accounts -f 1155291 -x
```

## Additional Supplied Programs

---

```
From database "alvherre":
  Filenode      Table Name      Oid  Schema  Tablespace
-----
    155173      accounts      155173  public  pg_default
   1155291  accounts_pkey  1155291  public  pg_default

$ # show disk space for every db object
$ du [0-9]* |
> while read SIZE FILENODE
> do
>   echo "$SIZE      `oid2name -q -d alvherre -i -f $FILENODE`"
> done
16          1155287  branches_pkey
16          1155289  tellers_pkey
17561      1155291  accounts_pkey
...

$ # same, but sort by size
$ du [0-9]* | sort -rn | while read SIZE FN
> do
>   echo "$SIZE      `oid2name -q -d alvherre -f $FN`"
> done
133466      155173      accounts
17561      1155291  accounts_pkey
1177       16717      pg_proc_proname_args_nsp_index
...

$ # If you want to see what's in tablespaces, use the pg_tblspc directory
$ cd $PGDATA/pg_tblspc
$ oid2name -s
All tablespaces:
  Oid  Tablespace Name
-----
    1663      pg_default
    1664      pg_global
   155151      fastdisk
   155152      bigdisk

$ # what databases have objects in tablespace "fastdisk"?
$ ls -d 155151/*
155151/17228/ 155151/PG_VERSION

$ # Oh, what was database 17228 again?
$ oid2name
All databases:
  Oid  Database Name  Tablespace
-----
   17228      alvherre  pg_default
   17255      regression  pg_default
   17227      template0  pg_default
    1       template1  pg_default

### Description

pg\_probackup is a utility to manage backup and recovery of Postgres Pro database clusters. It is designed to perform periodic backups of the Postgres Pro instance that enable you to restore the server in case of a failure. pg\_probackup supports PostgreSQL 9.5 or higher.

- [Overview](#)
- [Installation and Setup](#)
- [Command-Line Reference](#)
- [Usage](#)

### Overview

As compared to other backup solutions, pg\_probackup offers the following benefits that can help you implement different backup strategies and deal with large amounts of data:

- Incremental backup: with three different incremental modes, you can plan the backup strategy in accordance with your data flow. Incremental backups allow you to save disk space and speed up backup as compared to taking full backups. It is also faster to restore the cluster by applying incremental backups than by replaying WAL files.
- Incremental restore: speed up restore from backup by reusing valid unchanged pages available in PGDATA.
- Validation: automatic data consistency checks and on-demand backup validation without actual data recovery.
- Verification: on-demand verification of Postgres Pro instance with the `checkdb` command.
- Retention: managing WAL archive and backups in accordance with retention policy. You can configure retention policy based on recovery time or the number of backups to keep, as well as specify time to live (TTL) for a particular backup. Expired backups can be merged or deleted.
- Parallelization: running `backup`, `restore`, `merge`, `delete`, `validate`, and `checkdb` processes on multiple parallel threads.
- Compression: storing backup data in a compressed state to save disk space.
- Deduplication: saving disk space by excluding non-data files (such as `_vm` or `_fsm`) from incremental backups if these files have not changed since they were copied into one of the previous backups in this incremental chain.
- Remote operations: backing up Postgres Pro instance located on a remote system or restoring a backup remotely.
- Backup from standby: avoiding extra load on master by taking backups from a standby server.
- External directories: backing up files and directories located outside of the Postgres Pro data directory (PGDATA), such as scripts, configuration files, logs, or SQL dump files.
- Backup catalog: getting the list of backups and the corresponding meta information in plain text or JSON formats.
- Archive catalog: getting the list of all WAL timelines and the corresponding meta information in plain text or JSON formats.
- Partial restore: restoring only the specified databases.
- Catchup: cloning a Postgres Pro instance for a fallen-behind standby server to “catch up” with master.

To manage backup data, `pg_probackup` creates a *backup catalog*. This is a directory that stores all backup files with additional meta information, as well as WAL archives required for point-in-time recovery. You can store backups for different instances in separate subdirectories of a single backup catalog.

Using `pg_probackup`, you can take full or incremental [backups](#):

- FULL backups contain all the data files required to restore the database cluster.
- Incremental backups operate at the page level, only storing the data that has changed since the previous backup. It allows you to save disk space and speed up the backup process as compared to taking full backups. It is also faster to restore the cluster by applying incremental backups than by replaying WAL files. `pg_probackup` supports the following modes of incremental backups:
  - DELTA backup. In this mode, `pg_probackup` reads all data files in the data directory and copies only those pages that have changed since the previous backup. This mode can impose read-only I/O pressure equal to a full backup.
  - PAGE backup. In this mode, `pg_probackup` scans all WAL files in the archive from the moment the previous full or incremental backup was taken. Newly created backups contain only the pages that were mentioned in WAL records. This requires all the WAL files since the previous backup to be present in the WAL archive. If the size of these files is comparable to the total size of the database cluster files, speedup is smaller, but the backup still takes less space. You have to configure WAL archiving as explained in [Setting up continuous WAL archiving](#) to make PAGE backups.
  - PTRACK backup. In this mode, Postgres Pro tracks page changes on the fly. Continuous archiving is not necessary for it to operate. Each time a relation page is updated, this page is marked in a special PTRACK bitmap. Tracking implies some minor overhead on the database server operation, but speeds up incremental backups significantly.

`pg_probackup` can take only physical online backups, and online backups require WAL for consistent recovery. So regardless of the chosen backup mode (FULL, PAGE or DELTA), any backup taken with `pg_probackup` must use one of the following *WAL delivery modes*:

- **ARCHIVE**. Such backups rely on [continuous archiving](#) to ensure consistent recovery. This is the default WAL delivery mode.
- **STREAM**. Such backups include all the files required to restore the cluster to a consistent state at the time the backup was taken. Regardless of [continuous archiving](#) having been set up or not, the WAL segments required for consistent recovery are streamed via replication protocol during backup and included into the backup files. That's why such backups are called *autonomous*, or *standalone*.

## Limitations

`pg_probackup` currently has the following limitations:

- `pg_probackup` only supports PostgreSQL 9.5 and higher.
- The remote mode is not supported on Windows systems.
- On Unix systems, for Postgres Pro 10 or lower, a backup can be made only by the same OS user that has started the Postgres Pro server. For example, if Postgres Pro server is started by user `postgres`, the `backup` command must also be run by user `postgres`. To satisfy this requirement when taking backups in the [remote mode](#) using SSH, you must set `--remote-user` option to `postgres`.
- For Postgres Pro 9.5, functions `pg_create_restore_point(text)` and `pg_switch_xlog()` can be executed only if the backup role is a superuser, so backup of a cluster with low amount of WAL traffic by a non-superuser role can take longer than the backup of the same cluster by a superuser role.
- The Postgres Pro server from which the backup was taken and the restored server must be compatible by the [block\\_size](#) and [wal\\_block\\_size](#) parameters and have the same major release number. Depending on cluster configuration, Postgres Pro itself may apply additional restrictions, such as CPU architecture or `libc/libicu` versions.

## Installation and Setup

Once you have `pg_probackup` installed, complete the following setup:

- Initialize the backup catalog.
- Add a new backup instance to the backup catalog.
- Configure the database cluster to enable `pg_probackup` backups.
- Optionally, configure SSH for running `pg_probackup` operations in the remote mode.

### Initializing the Backup Catalog

`pg_probackup` stores all WAL and backup files in the corresponding subdirectories of the backup catalog.

To initialize the backup catalog, run the following command:

```
pg_probackup init -B backup_dir
```

where `backup_dir` is the path to the backup catalog. If the `backup_dir` already exists, it must be empty. Otherwise, `pg_probackup` returns an error.

The user launching `pg_probackup` must have full access to the `backup_dir` directory.

`pg_probackup` creates the `backup_dir` backup catalog, with the following subdirectories:

- `wal/` — directory for WAL files.
- `backups/` — directory for backup files.

Once the backup catalog is initialized, you can add a new backup instance.

## Adding a New Backup Instance

`pg_probackup` can store backups for multiple database clusters in a single backup catalog. To set up the required subdirectories, you must add a backup instance to the backup catalog for each database cluster you are going to back up.

To add a new backup instance, run the following command:

```
pg_probackup add-instance -B backup_dir -D data_dir --instance instance_name
  [remote_options]
```

where:

- `data_dir` is the data directory of the cluster you are going to back up. To set up and use `pg_probackup`, write access to this directory is required.
- `instance_name` is the name of the subdirectories that will store WAL and backup files for this cluster.
- `remote_options` are optional parameters that need to be specified only if `data_dir` is located on a remote system.

`pg_probackup` creates the `instance_name` subdirectories under the `backups/` and `wal/` directories of the backup catalog. The `backups/instance_name` directory contains the `pg_probackup.conf` configuration file that controls `pg_probackup` settings for this backup instance. If you run this command with the `remote_options`, the specified parameters will be added to `pg_probackup.conf`.

For details on how to fine-tune `pg_probackup` configuration, see [the section called “Configuring `pg\_probackup`”](#).

The user launching `pg_probackup` must have full access to `backup_dir` directory and at least read-only access to `data_dir` directory. If you specify the path to the backup catalog in the `BACKUP_PATH` environment variable, you can omit the corresponding option when running `pg_probackup` commands.

### Note

For Postgres Pro 11 or higher, it is recommended to use the [group access](#) feature, so that backup can be done by any OS user in the same group as the cluster owner. In this case, the user should have read permissions for the cluster directory.

## Configuring the Database Cluster

Although `pg_probackup` can be used by a superuser, it is recommended to create a separate role with the minimum permissions required for the chosen backup strategy. In these configuration instructions, the `backup` role is used as an example.

To perform a [backup](#), the following permissions for role `backup` are required only in the database **used for connection** to the Postgres Pro server:

For Postgres Pro 9.5:

```
BEGIN;
CREATE ROLE backup WITH LOGIN;
GRANT USAGE ON SCHEMA pg_catalog TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.current_setting(text) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.set_config(text, text, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_is_in_recovery() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_start_backup(text, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_stop_backup() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_create_restore_point(text) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_switch_xlog() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current() TO backup;
```

```
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current_snapshot() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_snapshot_xmax(txid_snapshot) TO backup;
COMMIT;
```

### For Postgres Pro 9.6:

```
BEGIN;
CREATE ROLE backup WITH LOGIN;
GRANT USAGE ON SCHEMA pg_catalog TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.current_setting(text) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.set_config(text, text, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_is_in_recovery() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_start_backup(text, boolean, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_stop_backup(boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_create_restore_point(text) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_switch_xlog() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_last_xlog_replay_location() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current_snapshot() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_snapshot_xmax(txid_snapshot) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_control_checkpoint() TO backup;
COMMIT;
```

### For Postgres Pro 10 or higher:

```
BEGIN;
CREATE ROLE backup WITH LOGIN;
GRANT USAGE ON SCHEMA pg_catalog TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.current_setting(text) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.set_config(text, text, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_is_in_recovery() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_start_backup(text, boolean, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_stop_backup(boolean, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_create_restore_point(text) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_switch_wal() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_last_wal_replay_lsn() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current_snapshot() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_snapshot_xmax(txid_snapshot) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_control_checkpoint() TO backup;
COMMIT;
```

In the [pg\\_hba.conf](#) file, allow connection to the database cluster on behalf of the `backup` role.

Since `pg_probackup` needs to read cluster files directly, `pg_probackup` must be started by (or connected to, if used in the remote mode) the OS user that has read access to all files and directories inside the data directory (`PGDATA`) you are going to back up.

Depending on whether you plan to take [standalone](#) or [archive](#) backups, Postgres Pro cluster configuration will differ, as specified in the sections below. To back up the database cluster from a standby server, run `pg_probackup` in the remote mode, or create PTRACK backups, additional setup is required.

For details, see the sections [Setting up STREAM Backups](#), [Setting up continuous WAL archiving](#), [Setting up Backup from Standby](#), [Configuring the Remote Mode](#), [Setting up Partial Restore](#), and [Setting up PTRACK Backups](#).

## Setting up STREAM Backups

To set up the cluster for [STREAM](#) backups, complete the following steps:

- Grant the `REPLICATION` privilege to the `backup` role:

```
ALTER ROLE backup WITH REPLICATION;
```

- In the `pg_hba.conf` file, allow replication on behalf of the `backup` role.
- Make sure the parameter `max_wal_senders` is set high enough to leave at least one session available for the backup process.
- Set the parameter `wal_level` to be higher than `minimal`.

If you are planning to take PAGE backups in the STREAM mode or perform PITR with STREAM backups, you still have to configure WAL archiving, as explained in the section [Setting up continuous WAL archiving](#).

Once these steps are complete, you can start taking FULL, PAGE, DELTA, and PTRACK backups in the STREAM WAL mode.

### Note

If you are planning to rely on `.pgpass` for authentication when running backup in STREAM mode, then `.pgpass` must contain credentials for `replication` database, used to establish connection via replication protocol. Example: `pghost:5432:replication:backup_user:my_strong_password`

## Setting up Continuous WAL Archiving

Making backups in PAGE backup mode, performing PITR and making backups with ARCHIVE WAL delivery mode require [continuous WAL archiving](#) to be enabled. To set up continuous archiving in the cluster, complete the following steps:

- Make sure the `wal_level` parameter is higher than `minimal`.
- If you are configuring archiving on master, `archive_mode` must be set to `on` or `always`. To perform archiving on standby, set this parameter to `always`.
- Set the `archive_command` parameter, as follows:

```
archive_command = '"install_dir/pg_probackup" archive-push -B "backup_dir" --
instance instance_name --wal-file-name=%f [remote_options]'
```

where `install_dir` is the installation directory of the `pg_probackup` version you are going to use, `backup_dir` and `instance_name` refer to the already initialized backup catalog instance for this database cluster, and `remote_options` only need to be specified to archive WAL on a remote host. For details about all possible `archive-push` parameters, see the section [archive-push](#).

Once these steps are complete, you can start making backups in the ARCHIVE WAL mode, backups in the PAGE backup mode, as well as perform PITR.

You can view the current state of the WAL archive using the `show` command. For details, see [the section called "Viewing WAL Archive Information"](#).

If you are planning to make PAGE backups and/or backups with ARCHIVE WAL mode from a standby server that generates a small amount of WAL traffic, without long waiting for WAL segment to fill up, consider setting the `archive_timeout` Postgres Pro parameter **on master**. The value of this parameter should be slightly lower than the `--archive-timeout` setting (5 minutes by default), so that there is enough time for the rotated segment to be streamed to standby and sent to WAL archive before the backup is aborted because of `--archive-timeout`.

### Note

Instead of using the `archive-push` command provided by `pg_probackup`, you can use any other tool to set up continuous archiving as long as it delivers WAL segments into `backup_dir/wal/`

*instance\_name* directory. If compression is used, it should be `gzip`, and `.gz` suffix in filename is mandatory.

### Note

Instead of configuring continuous archiving by setting the `archive_mode` and `archive_command` parameters, you can opt for using the `pg_receivewal` utility. In this case, `pg_receivewal -D directory` option should point to `backup_dir/wal/instance_name` directory. `pg_probackup` supports WAL compression that can be done by `pg_receivewal`. “Zero Data Loss” archive strategy can be achieved only by using `pg_receivewal`.

### Setting up Backup from Standby

For Postgres Pro 9.6 or higher, `pg_probackup` can take backups from a standby server. This requires the following additional setup:

- On the standby server, set the `hot_standby` parameter to `on`.
- On the master server, set the `full_page_writes` parameter to `on`.
- To perform standalone backups on standby, complete all steps in section [Setting up STREAM Backups](#).
- To perform archive backups on standby, complete all steps in section [Setting up continuous WAL archiving](#).

Once these steps are complete, you can start taking FULL, PAGE, DELTA, or PTRACK backups with appropriate WAL delivery mode: ARCHIVE or STREAM, from the standby server.

Backup from the standby server has the following limitations:

- If the standby is promoted to the master during backup, the backup fails.
- All WAL records required for the backup must contain sufficient full-page writes. This requires you to enable `full_page_writes` on the master, and not to use tools like `pg_compresslog` as `archive_command` to remove full-page writes from WAL files.

### Setting up Cluster Verification

Logical verification of a database cluster requires the following additional setup. Role `backup` is used as an example:

- Install the `amcheck` or `amcheck_next` extension **in every database** of the cluster:

```
CREATE EXTENSION amcheck;
```

- Grant the following permissions to the `backup` role **in every database** of the cluster:

```
GRANT SELECT ON TABLE pg_catalog.pg_am TO backup;
GRANT SELECT ON TABLE pg_catalog.pg_class TO backup;
GRANT SELECT ON TABLE pg_catalog.pg_database TO backup;
GRANT SELECT ON TABLE pg_catalog.pg_namespace TO backup;
GRANT SELECT ON TABLE pg_catalog.pg_extension TO backup;
GRANT EXECUTE ON FUNCTION bt_index_check(regclass) TO backup;
GRANT EXECUTE ON FUNCTION bt_index_check(regclass, bool) TO backup;
GRANT EXECUTE ON FUNCTION bt_index_check(regclass, bool, bool) TO backup;
```

### Setting up Partial Restore

If you are planning to use partial restore, complete the following additional step:

- Grant the read-only access to `pg_catalog.pg_database` to the `backup` role **only in the database used for connection** to Postgres Pro server:

```
GRANT SELECT ON TABLE pg_catalog.pg_database TO backup;
```

## Configuring the Remote Mode

pg\_probackup supports the remote mode that allows to perform backup, restore and WAL archiving operations remotely. In this mode, the backup catalog is stored on a local system, while Postgres Pro instance to backup and/or to restore is located on a remote system. Currently the only supported remote protocol is SSH.

### Set up SSH

If you are going to use pg\_probackup in remote mode via SSH, complete the following steps:

- Install pg\_probackup on both systems: `backup_host` and `db_host`.
- For communication between the hosts set up the passwordless SSH connection between `backup` user on `backup_host` and `postgres` user on `db_host`:

```
[backup@backup_host] ssh-copy-id postgres@db_host
```

- If you are going to rely on [continuous WAL archiving](#), set up passwordless SSH connection between `postgres` user on `db_host` and `backup` user on `backup_host`:

```
[postgres@db_host] ssh-copy-id backup@backup_host
```

where:

- `backup_host` is the system with *backup catalog*.
- `db_host` is the system with Postgres Pro cluster.
- `backup` is the OS user on `backup_host` used to run pg\_probackup.
- `postgres` is the OS user on `db_host` used to start the Postgres Pro cluster. For Postgres Pro 11 or higher a more secure approach can be used thanks to [group access](#) feature.

pg\_probackup in the remote mode via SSH works as follows:

- Only the following commands can be launched in the remote mode: [add-instance](#), [backup](#), [restore](#), [catchup](#), [archive-push](#), and [archive-get](#).
- Operating in remote mode requires pg\_probackup binary to be installed on both local and remote systems. The versions of local and remote binary must be the same.
- When started in the remote mode, the main pg\_probackup process on the local system connects to the remote system via SSH and launches one or more agent processes on the remote system, which are called *remote agents*. The number of remote agents is equal to the `-j/--threads` setting.
- The main pg\_probackup process uses remote agents to access remote files and transfer data between local and remote systems.
- Remote agents try to minimize the network traffic and the number of round-trips between hosts.
- The main process is usually started on `backup_host` and connects to `db_host`, but in case of `archive-push` and `archive-get` commands the main process is started on `db_host` and connects to `backup_host`.
- Once data transfer is complete, remote agents are terminated and SSH connections are closed.
- If an error condition is encountered by a remote agent, then all agents are terminated and error details are reported by the main pg\_probackup process, which exits with an error.
- Compression is always done on `db_host`, while decompression is always done on `backup_host`.

### Note

You can impose [additional restrictions](#) on SSH settings to protect the system in the event of account compromise.

## Setting up PTRACK Backups

### Note

PTRACK versions lower than 2.0 are deprecated and not supported. Postgres Pro Standard and Postgres Pro Enterprise versions starting with 11.9.1 contain PTRACK 2.0. Upgrade your server to avoid issues in backups that you will take in future and be sure to take fresh backups of your clusters with the upgraded PTRACK since the backups taken with PTRACK 1.x might be corrupt.

If you are going to use PTRACK backups, complete the following additional steps. The role that will perform PTRACK backups (the `backup` role in the examples below) must have access to all the databases of the cluster.

For Postgres Pro 11 or higher:

1. Create PTRACK extension:

```
CREATE EXTENSION ptrack;
```

2. To enable tracking page updates, set `ptrack.map_size` parameter to a positive integer and restart the server.

For optimal performance, it is recommended to set `ptrack.map_size` to  $N / 1024$ , where  $N$  is the size of the Postgres Pro cluster, in MB. If you set this parameter to a lower value, PTRACK is more likely to map several blocks together, which leads to false-positive results when tracking changed blocks and increases the incremental backup size as unchanged blocks can also be copied into the incremental backup. Setting `ptrack.map_size` to a higher value does not affect PTRACK operation, but it is not recommended to set this parameter to a value higher than 1024.

### Note

If you change the `ptrack.map_size` parameter value, the previously created PTRACK map file is cleared, and tracking newly changed blocks starts from scratch. Thus, you have to retake a full backup before taking incremental PTRACK backups after changing `ptrack.map_size`.

## Usage

### Creating a Backup

To create a backup, run the following command:

```
pg_probackup backup -B backup_dir --instance instance_name -b backup_mode
```

Where `backup_mode` can take one of the following values:

- FULL — creates a full backup that contains all the data files of the cluster to be restored.
- DELTA — reads all data files in the data directory and creates an incremental backup for pages that have changed since the previous backup.
- PAGE — creates an incremental backup based on the WAL files that have been generated since the previous full or incremental backup was taken. Only changed blocks are read from data files.
- PTRACK — creates an incremental backup tracking page changes on the fly.

When restoring a cluster from an incremental backup, `pg_probackup` relies on the parent full backup and all the incremental backups between them, which is called “the backup chain”. You must create at least one full backup before taking incremental ones.

### ARCHIVE Mode

ARCHIVE is the default WAL delivery mode.

For example, to make a FULL backup in ARCHIVE mode, run:

```
pg_probackup backup -B backup_dir --instance instance_name -b FULL
```

ARCHIVE backups rely on [continuous archiving](#) to get WAL segments required to restore the cluster to a consistent state at the time the backup was taken.

When a backup is taken, `pg_probackup` ensures that WAL files containing WAL records between `Start LSN` and `Stop LSN` actually exist in `backup_dir/wal/instance_name` directory. `pg_probackup` also ensures that WAL records between `Start LSN` and `Stop LSN` can be parsed. This precaution eliminates the risk of silent WAL corruption.

### STREAM Mode

STREAM is the optional WAL delivery mode.

For example, to make a FULL backup in the STREAM mode, add the `--stream` flag to the command from the previous example:

```
pg_probackup backup -B backup_dir --instance instance_name -b FULL --stream --temp-slot
```

The optional `--temp-slot` flag ensures that the required segments remain available if the WAL is rotated before the backup is complete.

Unlike backups in ARCHIVE mode, STREAM backups include all the WAL segments required to restore the cluster to a consistent state at the time the backup was taken.

During [backup](#) `pg_probackup` streams WAL files containing WAL records between `Start LSN` and `Stop LSN` to `backup_dir/backups/instance_name/backup_id/database/pg_wal` directory. To eliminate the risk of silent WAL corruption, `pg_probackup` also checks that WAL records between `Start LSN` and `Stop LSN` can be parsed.

Even if you are using [continuous archiving](#), STREAM backups can still be useful in the following cases:

- STREAM backups can be restored on the server that has no file access to WAL archive.
- STREAM backups enable you to restore the cluster state at the point in time for which WAL files in archive are no longer available.
- Backup in STREAM mode can be taken from a standby of a server that generates small amount of WAL traffic, without long waiting for WAL segment to fill up.

### Page Validation

If [data checksums](#) are enabled in the database cluster, `pg_probackup` uses this information to check correctness of data files during backup. While reading each page, `pg_probackup` checks whether the calculated checksum coincides with the checksum stored in the page header. This guarantees that the Postgres Pro instance and the backup itself have no corrupt pages. Note that `pg_probackup` reads database files directly from the filesystem, so under heavy write load during backup it can show false-positive checksum mismatches because of partial writes. If a page checksum mismatch occurs, the page is re-read and checksum comparison is repeated.

A page is considered corrupt if checksum comparison has failed more than 100 times. In this case, the backup is aborted.

Even if data checksums are not enabled, `pg_probackup` always performs sanity checks for page headers.

### External Directories

To back up a directory located outside of the data directory, use the optional `--external-dirs` parameter that specifies the path to this directory. If you would like to add more than one external directory, you can provide several paths separated by colons on Linux systems or semicolons on Windows systems.

For example, to include `/etc/dir1` and `/etc/dir2` directories into the full backup of your `instance_name` instance that will be stored under the `backup_dir` directory on Linux, run:

```
pg_probackup backup -B backup_dir --instance instance_name -b FULL --external-dirs=/etc/dir1:/etc/dir2
```

Similarly, to include `C:\dir1` and `C:\dir2` directories into the full backup on Windows, run:

```
pg_probackup backup -B backup_dir --instance instance_name -b FULL --external-dirs=C:\dir1;C:\dir2
```

`pg_probackup` recursively copies the contents of each external directory into a separate subdirectory in the backup catalog. Since external directories included into different backups do not have to be the same, when you are restoring the cluster from an incremental backup, only those directories that belong to this particular backup will be restored. Any external directories stored in the previous backups will be ignored.

To include the same directories into each backup of your instance, you can specify them in the `pg_probackup.conf` configuration file using the `set-config` command with the `--external-dirs` option.

## Performing Cluster Verification

To verify that Postgres Pro database cluster is not corrupt, run the following command:

```
pg_probackup checkdb [-B backup_dir [--instance instance_name]] [-D data_dir] [connection_options]
```

This command performs physical verification of all data files located in the specified data directory by running page header sanity checks, as well as block-level checksum verification if checksums are enabled. If a corrupt page is detected, `checkdb` continues cluster verification until all pages in the cluster are validated.

By default, similar [page validation](#) is performed automatically while a backup is taken by `pg_probackup`. The `checkdb` command enables you to perform such page validation on demand, without taking any backup copies, even if the cluster is not backed up using `pg_probackup` at all.

To perform cluster verification, `pg_probackup` needs to connect to the cluster to be verified. In general, it is enough to specify the backup instance of this cluster for `pg_probackup` to determine the required connection options. However, if `-B` and `--instance` options are omitted, you have to provide [connection options](#) and `data_dir` via environment variables or command-line options.

Physical verification cannot detect logical inconsistencies, missing or nullified blocks and entire files, or similar anomalies. Extensions [amcheck](#) and [amcheck\\_next](#) provide a partial solution to these problems.

If you would like, in addition to physical verification, to verify all indexes in all databases using these extensions, you can specify the `--amcheck` flag when running the `checkdb` command:

```
pg_probackup checkdb -D data_dir --amcheck [connection_options]
```

You can skip physical verification by specifying the `--skip-block-validation` flag. In this case, you can omit `backup_dir` and `data_dir` options, only [connection options](#) are mandatory:

```
pg_probackup checkdb --amcheck --skip-block-validation [connection_options]
```

Logical verification can be done more thoroughly with the `--heapallindexed` flag by checking that all heap tuples that should be indexed are actually indexed, but at the higher cost of CPU, memory, and I/O consumption.

## Validating a Backup

`pg_probackup` calculates checksums for each file in a backup during the backup process. The process of checking checksums of backup data files is called *the backup validation*. By default, validation is run immediately after the backup is taken and right before the restore, to detect possible backup corruption.

If you would like to skip backup validation, you can specify the `--no-validate` flag when running `backup` and `restore` commands.

To ensure that all the required backup files are present and can be used to restore the database cluster, you can run the `validate` command with the exact [recovery target options](#) you are going to use for recovery.

For example, to check that you can restore the database cluster from a backup copy up to transaction ID 4242, run this command:

```
pg_probackup validate -B backup_dir --instance instance_name --recovery-target-xid=4242
```

If validation completes successfully, `pg_probackup` displays the corresponding message. If validation fails, you will receive an error message with the exact time, transaction ID, and LSN up to which the recovery is possible.

If you specify `backup_id` via `-i/--backup-id` option, then only the backup copy with specified backup ID will be validated. If `backup_id` is specified with [recovery target options](#), the `validate` command will check whether it is possible to restore the specified backup to the specified recovery target.

For example, to check that you can restore the database cluster from a backup copy with the `PT8XFX` backup ID up to the specified timestamp, run this command:

```
pg_probackup validate -B backup_dir --instance instance_name -i PT8XFX --recovery-target-time="2017-05-18 14:18:11+03"
```

If you specify the `backup_id` of an incremental backup, all its parents starting from FULL backup will be validated.

If you omit all the parameters, all backups are validated.

## Restoring a Cluster

To restore the database cluster from a backup, run the `restore` command with at least the following options:

```
pg_probackup restore -B backup_dir --instance instance_name -i backup_id
```

where:

- `backup_dir` is the backup catalog that stores all backup files and meta information.
- `instance_name` is the backup instance for the cluster to be restored.
- `backup_id` specifies the backup to restore the cluster from. If you omit this option, `pg_probackup` uses the latest valid backup available for the specified instance. If you specify an incremental backup to restore, `pg_probackup` automatically restores the underlying full backup and then sequentially applies all the necessary increments.

Once the `restore` command is complete, start the database service.

If you restore [ARCHIVE](#) backups, perform [PITR](#), or specify the `--restore-as-replica` flag with the `restore` command to set up a standby server, `pg_probackup` creates a recovery configuration file once all data files are copied into the target directory. This file includes the minimal settings required for recovery, except for the password in the [primary\\_conninfo](#) parameter; you have to add the password manually or use the `--primary-conninfo` option, if required. For Postgres Pro 11 or lower, recovery settings are written into the `recovery.conf` file. Starting from Postgres Pro 12, `pg_probackup` writes these settings into the `probackup_recovery.conf` file and then includes it into `postgresql.auto.conf`.

If you are restoring a [STREAM](#) backup, the restore is complete at once, with the cluster returned to a self-consistent state at the point when the backup was taken. For [ARCHIVE](#) backups, Postgres Pro replays all available archived WAL segments, so the cluster is restored to the latest state possible within the current timeline. You can change this behavior by using the [recovery target options](#) with the `restore` command, as explained in [the section called “Performing Point-in-Time \(PITR\) Recovery”](#).

If the cluster to restore contains tablespaces, `pg_probackup` restores them to their original location by default. To restore tablespaces to a different location, use the `--tablespace-mapping/-T` option.

Otherwise, restoring the cluster on the same host will fail if tablespaces are in use, because the backup would have to be written to the same directories.

When using the `--tablespace-mapping/-T` option, you must provide absolute paths to the old and new tablespace directories. If a path happens to contain an equals sign (=), escape it with a backslash. This option can be specified multiple times for multiple tablespaces. For example:

```
pg_probackup restore -B backup_dir --instance instance_name -D data_dir -j 4 -
i backup_id -T tablespace1_dir=tablespace1_newdir -T tablespace2_dir=tablespace2_newdir
```

To restore the cluster on a remote host, follow the instructions in [the section called “Using pg\\_probackup in the Remote Mode”](#).

### Note

By default, the `restore` command validates the specified backup before restoring the cluster. If you run regular backup validations and would like to save time when restoring the cluster, you can specify the `--no-validate` flag to skip validation and speed up the recovery.

### Incremental Restore

The speed of restore from backup can be significantly improved by replacing only invalid and changed pages in already existing Postgres Pro data directory using [incremental restore options](#) with the `restore` command.

To restore the database cluster from a backup in incremental mode, run the `restore` command with the following options:

```
pg_probackup restore -B backup_dir --instance instance_name -D data_dir -
I incremental_mode
```

Where `incremental_mode` can take one of the following values:

- **CHECKSUM** — read all data files in the data directory, validate header and checksum in every page and replace only invalid pages and those with checksum and LSN not matching with corresponding page in backup. This is the simplest, the most fool-proof incremental mode. Recommended to use by default.
- **LSN** — read the `pg_control` in the data directory to obtain redo LSN and redo TLI, which allows to determine a point in history(shiftpoint), where data directory state shifted from target backup chain history. If shiftpoint is not within reach of backup chain history, then restore is aborted. If shiftpoint is within reach of backup chain history, then read all data files in the data directory, validate header and checksum in every page and replace only invalid pages and those with LSN greater than shiftpoint. This mode offers a greater speed up compared to CHECKSUM, but rely on two conditions to be met. First, [data checksums](#) parameter must be enabled in data directory (to avoid corruption due to hint bits). This condition will be checked at the start of incremental restore and the operation will be aborted if checksums are disabled. Second, the `pg_control` file must be synched with state of data directory. This condition cannot be checked at the start of restore, so it is a user responsibility to ensure that `pg_control` contain valid information. Therefore it is not recommended to use LSN mode in any situation, where `pg_control` cannot be trusted or has been tampered with: after `pg_resetxlog` execution, after restore from backup without recovery been run, etc.
- **NONE** — regular restore without any incremental optimizations.

Regardless of chosen incremental mode, `pg_probackup` will check, that postmaster in given destination directory is not running and `system-identifier` is the same as in the backup.

Suppose you want to return an old master as replica after switchover using incremental restore in LSN mode:

## Additional Supplied Programs

Instance Data	Version WAL	ID Zratio	Recovery Time Start LSN	Stop LSN	Mode Status	WAL Mode	TLI	Time
node	12	QBRNBP	2020-06-11 17:40:58+03		DELTA	ARCHIVE	16/15	40s

INFO: Restore of backup QBRNBP completed.
```

### Note

Incremental restore is possible only for backups with `program_version` equal or greater than 2.4.0.

### Partial Restore

If you have enabled [partial restore](#) before taking backups, you can restore only some of the databases using [partial restore options](#) with the `restore` commands.

To restore the specified databases only, run the `restore` command with the following options:

```
pg_probackup restore -B backup_dir --instance instance_name --db-include=database_name
```

The `--db-include` option can be specified multiple times. For example, to restore only databases `db1` and `db2`, run the following command:

```
pg_probackup restore -B backup_dir --instance instance_name --db-include=db1 --db-include=db2
```

To exclude one or more databases from restore, use the `--db-exclude` option:

```
pg_probackup restore -B backup_dir --instance instance_name --db-exclude=database_name
```

The `--db-exclude` option can be specified multiple times. For example, to exclude the databases `db1` and `db2` from restore, run the following command:

```
pg_probackup restore -B backup_dir --instance instance_name --db-exclude=db1 --db-exclude=db2
```

Partial restore relies on lax behavior of Postgres Pro recovery process toward truncated files. For recovery to work properly, files of excluded databases are restored as files of zero size. After the Postgres Pro cluster is successfully started, you must drop the excluded databases using `DROP DATABASE` command.

To decouple a single cluster containing multiple databases into separate clusters with minimal downtime, you can do partial restore of the cluster as a standby using the `--restore-as-replica` option for specific databases.

### Note

The `template0` and `template1` databases are always restored.

### Note

Due to recovery specifics of Postgres Pro versions earlier than 12, it is advisable that you set the `hot standby` parameter to `off` when running partial restore of a Postgres Pro cluster of version earlier than 12. Otherwise the recovery may fail.

## Performing Point-in-Time (PITR) Recovery

If you have enabled [continuous WAL archiving](#) before taking backups, you can restore the cluster to its state at an arbitrary point in time (recovery target) using [recovery target options](#) with the `restore` command.

You can use both STREAM and ARCHIVE backups for point in time recovery as long as the WAL archive is available at least starting from the time the backup was taken. If `-i/--backup-id` option is omitted, `pg_probackup` automatically chooses the backup that is the closest to the specified recovery target and starts the restore process, otherwise `pg_probackup` will try to restore the specified backup to the specified recovery target.

- To restore the cluster state at the exact time, specify the `--recovery-target-time` option, in the timestamp format. For example:

```
pg_probackup restore -B backup_dir --instance instance_name --recovery-target-time="2017-05-18 14:18:11+03"
```

- To restore the cluster state up to a specific transaction ID, use the `--recovery-target-xid` option:

```
pg_probackup restore -B backup_dir --instance instance_name --recovery-target-xid=687
```

- To restore the cluster state up to the specific LSN, use `--recovery-target-lsn` option:

```
pg_probackup restore -B backup_dir --instance instance_name --recovery-target-lsn=16/B374D848
```

- To restore the cluster state up to the specific named restore point, use `--recovery-target-name` option:

```
pg_probackup restore -B backup_dir --instance instance_name --recovery-target-name="before_app_upgrade"
```

- To restore the backup to the latest state available in the WAL archive, use `--recovery-target` option with `latest` value:

```
pg_probackup restore -B backup_dir --instance instance_name --recovery-target="latest"
```

- To restore the cluster to the earliest point of consistency, use `--recovery-target` option with the `immediate` value:

```
pg_probackup restore -B backup_dir --instance instance_name --recovery-  
target='immediate'
```

### Using pg\_probackup in the Remote Mode

`pg_probackup` supports the remote mode that allows to perform `backup` and `restore` operations remotely via SSH. In this mode, the backup catalog is stored on a local system, while Postgres Pro instance to be backed up is located on a remote system. You must have `pg_probackup` installed on both systems.

#### Note

`pg_probackup` relies on passwordless SSH connection for communication between the hosts.

The typical workflow is as follows:

- On your backup host, configure `pg_probackup` as explained in the section [Installation and Setup](#). For the `add-instance` and `set-config` commands, make sure to specify `remote options` that point to the database host with the Postgres Pro instance.
- If you would like to take remote backups in `PAGE` mode, or rely on `ARCHIVE` WAL delivery mode, or use `PITR`, configure continuous WAL archiving from the database host to the backup host as explained in the section [Setting up continuous WAL archiving](#). For the `archive-push` and `archive-get` commands, you must specify the `remote options` that point to the backup host with the backup catalog.
- Run `backup` or `restore` commands with `remote options on the backup host`. `pg_probackup` connects to the remote system via SSH and creates a backup locally or restores the previously taken backup on the remote system, respectively.

For example, to create an archive full backup of a Postgres Pro cluster located on a remote system with host address `192.168.0.2` on behalf of the `postgres` user via SSH connection through port `2302`, run:

```
pg_probackup backup -B backup_dir --instance instance_name -b FULL --remote-  
user=postgres --remote-host=192.168.0.2 --remote-port=2302
```

To restore the latest available backup on a remote system with host address `192.168.0.2` on behalf of the `postgres` user via SSH connection through port `2302`, run:

```
pg_probackup restore -B backup_dir --instance instance_name --remote-user=postgres --  
remote-host=192.168.0.2 --remote-port=2302
```

Restoring an `ARCHIVE` backup or performing `PITR` in the remote mode require additional information: destination address, port and username for establishing an SSH connection **from** the host with database **to** the host with the backup catalog. This information will be used by the `restore_command` to copy WAL segments from the archive to the Postgres Pro `pg_wal` directory.

To solve this problem, you can use [Remote WAL Archive Options](#).

For example, to restore latest backup on remote system using remote mode through SSH connection to user `postgres` on host with address `192.168.0.2` via port `2302` and user `backup` on backup catalog host with address `192.168.0.3` via port `2303`, run:

```
pg_probackup restore -B backup_dir --instance instance_name --remote-user=postgres  
--remote-host=192.168.0.2 --remote-port=2302 --archive-host=192.168.0.3 --archive-  
port=2303 --archive-user=backup
```

Provided arguments will be used to construct the `restore_command`:

```
restore_command = '"install_dir/pg_probackup" archive-get -B "backup_dir" --
instance instance_name --wal-file-path=%p --wal-file-name=%f --remote-host=192.168.0.3
--remote-port=2303 --remote-user=backup'
```

Alternatively, you can use the `--restore-command` option to provide the entire `restore_command`:

```
pg_probackup restore -B backup_dir --instance instance_name --remote-user=postgres
--remote-host=192.168.0.2 --remote-port=2302 --restore-command='"install_dir/
pg_probackup" archive-get -B "backup_dir" --instance instance_name --wal-file-path=%p
--wal-file-name=%f --remote-host=192.168.0.3 --remote-port=2303 --remote-user=backup'
```

### Note

The remote mode is currently unavailable for Windows systems.

## Running pg\_probackup on Parallel Threads

[backup](#), [restore](#), [merge](#), [delete](#), [catchup](#), [checkdb](#), and [validate](#) processes can be executed on several parallel threads. This can significantly speed up `pg_probackup` operation given enough resources (CPU cores, disk, and network bandwidth).

Parallel execution is controlled by the `-j/--threads` command-line option. For example, to create a backup using four parallel threads, run:

```
pg_probackup backup -B backup_dir --instance instance_name -b FULL -j 4
```

### Note

Parallel restore applies only to copying data from the backup catalog to the data directory of the cluster. When Postgres Pro server is started, WAL records need to be replayed, and this cannot be done in parallel.

## Configuring pg\_probackup

Once the backup catalog is initialized and a new backup instance is added, you can use the `pg_probackup.conf` configuration file located in the `backup_dir/backups/instance_name` directory to fine-tune `pg_probackup` configuration.

For example, [backup](#) and [checkdb](#) commands use a regular Postgres Pro connection. To avoid specifying [connection options](#) each time on the command line, you can set them in the `pg_probackup.conf` configuration file using the [set-config](#) command.

### Note

It is **not recommended** to edit `pg_probackup.conf` manually.

Initially, `pg_probackup.conf` contains the following settings:

- `PGDATA` — the path to the data directory of the cluster to back up.
- `system-identifier` — the unique identifier of the Postgres Pro instance.

Additionally, you can define [remote](#), [retention](#), [logging](#), and [compression](#) settings using the `set-config` command:

```
pg_probackup set-config -B backup_dir --instance instance_name
[--external-dirs=external_directory_path] [remote_options] [connection_options]
[retention_options] [logging_options]
```

To view the current settings, run the following command:

```
pg_probackup show-config -B backup_dir --instance instance_name
```

You can override the settings defined in `pg_probackup.conf` when running `pg_probackup` [commands](#) via the corresponding environment variables and/or command line options.

### Specifying Connection Settings

If you define connection settings in the `pg_probackup.conf` configuration file, you can omit connection options in all the subsequent `pg_probackup` commands. However, if the corresponding environment variables are set, they get higher priority. The options provided on the command line overwrite both environment variables and configuration file settings.

If nothing is given, the default values are taken. By default `pg_probackup` tries to use local connection via Unix domain socket (`localhost` on Windows) and tries to get the database name and the user name from the `PGUSER` environment variable or the current OS user name.

### Managing the Backup Catalog

With `pg_probackup`, you can manage backups from the command line:

- [View backup information](#)
- [View WAL Archive Information](#)
- [Validate backups](#)
- [Merge backups](#)
- [Delete backups](#)

### Viewing Backup Information

To view the list of existing backups for every instance, run the command:

```
pg_probackup show -B backup_dir
```

`pg_probackup` displays the list of all the available backups. For example:

```
BACKUP INSTANCE 'node'
```

Instance	Version	ID	Recovery time	Mode	WAL Mode	TLI	Time	Data
WAL	Zratio	Start LSN	Stop LSN	Status				
node	10	PYSUE8	2019-10-03 15:51:48+03	FULL	ARCHIVE	1/0	16s	9047kB
16MB	4.31	0/12000028	0/12000160	OK				
node	10	P7XDQV	2018-04-29 05:32:59+03	DELTA	STREAM	1/1	11s	19MB
16MB	1.00	0/15000060	0/15000198	OK				
node	10	P7XDJA	2018-04-29 05:28:36+03	PTRACK	STREAM	1/1	21s	32MB
32MB	1.00	0/13000028	0/13000198	OK				
node	10	P7XDHU	2018-04-29 05:27:59+03	PAGE	STREAM	1/1	15s	33MB
16MB	1.00	0/11000028	0/110001D0	OK				
node	10	P7XDHB	2018-04-29 05:27:15+03	FULL	STREAM	1/0	11s	39MB
16MB	1.00	0/F000028	0/F000198	OK				

For each backup, the following information is provided:

- Instance — the instance name.
- Version — Postgres Pro major version.
- ID — the backup identifier.
- Recovery time — the earliest moment for which you can restore the state of the database cluster.
- Mode — the method used to take this backup. Possible values: FULL, PAGE, DELTA, PTRACK.
- WAL Mode — WAL delivery mode. Possible values: STREAM and ARCHIVE.
- TLI — timeline identifiers of the current backup and its parent.

- **Time** — the time it took to perform the backup.
- **Data** — the size of the data files in this backup. This value does not include the size of WAL files. For **STREAM** backups, the total size of the backup can be calculated as **Data + WAL**.
- **WAL** — the uncompressed size of WAL files that need to be applied during recovery for the backup to reach a consistent state.
- **Zratio** — compression ratio calculated as “uncompressed-bytes” / “data-bytes”.
- **Start LSN** — WAL log sequence number corresponding to the start of the backup process. REDO point for Postgres Pro recovery process to start from.
- **Stop LSN** — WAL log sequence number corresponding to the end of the backup process. Consistency point for Postgres Pro recovery process.
- **Status** — backup status. Possible values:
  - **OK** — the backup is complete and valid.
  - **DONE** — the backup is complete, but was not validated.
  - **RUNNING** — the backup is in progress.
  - **MERGING** — the backup is being merged.
  - **MERGED** — the backup data files were successfully merged, but its metadata is in the process of being updated. Only full backups can have this status.
  - **DELETING** — the backup files are being deleted.
  - **CORRUPT** — some of the backup files are corrupt.
  - **ERROR** — the backup was aborted because of an unexpected error.
  - **ORPHAN** — the backup is invalid because one of its parent backups is corrupt or missing.

You can restore the cluster from the backup only if the backup status is **OK** or **DONE**.

To get more detailed information about the backup, run the `show` command with the backup ID:

```
pg_probackup show -B backup_dir --instance instance_name -i backup_id
```

The sample output is as follows:

```
#Configuration
backup-mode = FULL
stream = false
compress-alg = zlib
compress-level = 1
from-replica = false

#Compatibility
block-size = 8192
wal-block-size = 8192
checksum-version = 1
program-version = 2.1.3
server-version = 10

#Result backup info
timelineid = 1
start-lsn = 0/04000028
stop-lsn = 0/040000f8
start-time = '2017-05-16 12:57:29'
end-time = '2017-05-16 12:57:31'
recovery-xid = 597
recovery-time = '2017-05-16 12:57:31'
expire-time = '2020-05-16 12:57:31'
data-bytes = 22288792
wal-bytes = 16777216
```

```
uncompressed-bytes = 39961833
pgdata-bytes = 39859393
status = OK
parent-backup-id = 'PT8XFX'
primary_conninfo = 'user=backup passfile=/var/lib/pgsql/.pgpass port=5432
sslmode=disable sslcompression=1 target_session_attrs=any'
```

Detailed output has additional attributes:

- `compress-alg` — compression algorithm used during backup. Possible values: `zlib`, `pglz`, `none`.
- `compress-level` — compression level used during backup.
- `from-replica` — was this backup taken on standby? Possible values: `1`, `0`.
- `block-size` — the [block\\_size](#) setting of Postgres Pro cluster at the backup start.
- `checksum-version` — are [data\\_checksums](#) enabled in the backed up Postgres Pro cluster? Possible values: `1`, `0`.
- `program-version` — full version of `pg_probackup` binary used to create the backup.
- `start-time` — the backup start time.
- `end-time` — the backup end time.
- `expire-time` — the point in time when a pinned backup can be removed in accordance with retention policy. This attribute is only available for pinned backups.
- `uncompressed-bytes` — the size of data files before adding page headers and applying compression. You can evaluate the effectiveness of compression by comparing `uncompressed-bytes` to `data-bytes` if compression is used.
- `pgdata-bytes` — the size of Postgres Pro cluster data files at the time of backup. You can evaluate the effectiveness of an incremental backup by comparing `pgdata-bytes` to `uncompressed-bytes`.
- `recovery-xid` — transaction ID at the backup end time.
- `parent-backup-id` — ID of the parent backup. Available only for incremental backups.
- `primary_conninfo` — `libpq` connection parameters used to connect to the Postgres Pro cluster to take this backup. The password is not included.
- `note` — text note attached to backup.
- `content-crc` — CRC32 checksum of `backup_content.control` file. It is used to detect corruption of backup metainformation.

You can also get the detailed information about the backup in the JSON format:

```
pg_probackup show -B backup_dir --instance instance_name --format=json -i backup_id
```

The sample output is as follows:

```
[
  {
    "instance": "node",
    "backups": [
      {
        "id": "PT91HZ",
        "parent-backup-id": "PT8XFX",

        "primary_conninfo": "user=backup passfile=/var/lib/pgsql/.pgpass
port=5432 sslmode=disable sslcompression=1 target_session_attrs=any",
        "status": "OK"
    }
}
]
}
]

```

### Viewing WAL Archive Information

To view the information about WAL archive for every instance, run the command:

```
pg_probackup show -B backup_dir [--instance instance_name] --archive
```

`pg_probackup` displays the list of all the available WAL files grouped by timelines. For example:

```

ARCHIVE INSTANCE 'node'
=====

```

TLI	Parent TLI	Switchpoint	Min Segno	Max Segno	N
segments	Size	Zratio	N backups	Status

For each timeline, the following information is provided:

- TLI — timeline identifier.
- Parent TLI — identifier of the timeline from which this timeline branched off.
- Switchpoint — LSN of the moment when the timeline branched off from its parent timeline.
- Min Segno — the first WAL segment belonging to the timeline.
- Max Segno — the last WAL segment belonging to the timeline.
- N segments — number of WAL segments belonging to the timeline.
- Size — the size that files take on disk.
- Zratio — compression ratio calculated as  $N \text{ segments} * wal\_segment\_size * wal\_block\_size / \text{Size}$ .
- N backups — number of backups belonging to the timeline. To get the details about backups, use the JSON format.
- Status — status of the WAL archive for this timeline. Possible values:
  - OK — all WAL segments between Min Segno and Max Segno are present.
  - DEGRADED — some WAL segments between Min Segno and Max Segno are missing. To find out which files are lost, view this report in the JSON format.

To get more detailed information about the WAL archive in the JSON format, run the command:

```
pg_probackup show -B backup_dir [--instance instance_name] --archive --format=json
```

```

Most fields are consistent with the plain format, with some exceptions:

- The size is in bytes.
- The `closest-backup-id` attribute contains the ID of the most recent valid backup that belongs to one of the previous timelines. You can use this backup to perform point-in-time recovery to this timeline. If such a backup does not exist, this string is empty.
- The `lost-segments` array provides with information about intervals of missing segments in DEGRADED timelines. In OK timelines, the `lost-segments` array is empty.
- The `backups` array lists all backups belonging to the timeline. If the timeline has no backups, this array is empty.

### Configuring Retention Policy

With `pg_probackup`, you can configure retention policy to remove redundant backups, clean up unneeded WAL files, as well as pin specific backups to ensure they are kept for the specified time, as explained in the sections below. All these actions can be combined together in any way.

**Removing Redundant Backups**

By default, all backup copies created with `pg_probackup` are stored in the specified backup catalog. To save disk space, you can configure retention policy to remove redundant backup copies.

To configure retention policy, set one or more of the following variables in the `pg_probackup.conf` file via [set-config](#):

```
--retention-redundancy=redundancy
```

Specifies **the number of full backup copies** to keep in the backup catalog.

```
--retention-window=window
```

Defines the earliest point in time for which `pg_probackup` can complete the recovery. This option is set in **the number of days** from the current moment. For example, if `retention-window=7`, `pg_probackup` must keep at least one backup copy that is older than seven days, with all the corresponding WAL files, and all the backups that follow.

If both `--retention-redundancy` and `--retention-window` options are set, both these conditions have to be taken into account when purging the backup catalog. For example, if you set `--retention-redundancy=2` and `--retention-window=7`, `pg_probackup` has to keep two full backup copies, as well as all the backups required to ensure recoverability for the last seven days:

```
pg_probackup set-config -B backup_dir --instance instance_name --retention-redundancy=2
--retention-window=7
```

To clean up the backup catalog in accordance with retention policy, you have to run the [delete](#) command with [retention flags](#), as shown below, or use the [backup](#) command with these flags to process the outdated backup copies right when the new backup is created.

For example, to remove all backup copies that no longer satisfy the defined retention policy, run the following command with the `--delete-expired` flag:

```
pg_probackup delete -B backup_dir --instance instance_name --delete-expired
```

If you would like to also remove the WAL files that are no longer required for any of the backups, you should also specify the `--delete-wal` flag:

```
pg_probackup delete -B backup_dir --instance instance_name --delete-expired --delete-wal
```

You can also set or override the current retention policy by specifying `--retention-redundancy` and `--retention-window` options directly when running `delete` or `backup` commands:

```
pg_probackup delete -B backup_dir --instance instance_name --delete-expired --
retention-window=7 --retention-redundancy=2
```

Since incremental backups require that their parent full backup and all the preceding incremental backups are available, if any of such backups expire, they still cannot be removed while at least one incremental backup in this chain satisfies the retention policy. To avoid keeping expired backups that are still required to restore an active incremental one, you can merge them with this backup using the `--merge-expired` flag when running [backup](#) or [delete](#) commands.

Suppose you have backed up the `node` instance in the `backup_dir` directory, with the `--retention-window` option set to `7`, and you have the following backups available on April 10, 2019:

```
BACKUP INSTANCE 'node'
```

```
=====
Instance  Version  ID      Recovery time      Mode  WAL    TLI  Time    Data
WAL      Zratio  Start LSN    Stop LSN    Status
=====
```

## Additional Supplied Programs

```

node      10      P7XDHR  2019-04-10 05:27:15+03 FULL  STREAM  1/0   11s   200MB
16MB     1.0    0/18000059 0/18000197 OK
node      10      P7XDQV  2019-04-08 05:32:59+03 PAGE  STREAM  1/0   11s   19MB
16MB     1.0    0/15000060 0/15000198 OK
node      10      P7XDJA  2019-04-03 05:28:36+03 DELTA STREAM  1/0   21s   32MB
16MB     1.0    0/13000028 0/13000198 OK
-----retention
window-----
node      10      P7XDHU  2019-04-02 05:27:59+03 PAGE  STREAM  1/0   31s   33MB
16MB     1.0    0/11000028 0/110001D0 OK
node      10      P7XDHB  2019-04-01 05:27:15+03 FULL  STREAM  1/0   11s   200MB
16MB     1.0    0/F000028  0/F000198  OK
node      10      P7XDFT  2019-03-29 05:26:25+03 FULL  STREAM  1/0   11s   200MB
16MB     1.0    0/D000028  0/D000198  OK

```

Even though P7XDHB and P7XDHU backups are outside the retention window, they cannot be removed as it invalidates the succeeding incremental backups P7XDJA and P7XDQV that are still required, so, if you run the `delete` command with the `--delete-expired` flag, only the P7XDFT full backup will be removed.

With the `--merge-expired` option, the P7XDJA backup is merged with the underlying P7XDHU and P7XDHB backups and becomes a full one, so there is no need to keep these expired backups anymore:

```

pg_probackup delete -B backup_dir --instance node --delete-expired --merge-expired
pg_probackup show -B backup_dir

```

```

BACKUP INSTANCE 'node'

```

Instance	Version	ID	Recovery time	Mode	WAL	TLI	Time	Data
WAL	Zratio	Start LSN	Stop LSN	Status				
node	10	P7XDHR	2019-04-10 05:27:15+03	FULL	STREAM	1/0	11s	200MB
16MB	1.0	0/18000059	0/18000197	OK				
node	10	P7XDQV	2019-04-08 05:32:59+03	PAGE	STREAM	1/0	11s	19MB
16MB	1.0	0/15000060	0/15000198	OK				
node	10	P7XDJA	2019-04-03 05:28:36+03	FULL	STREAM	1/0	21s	32MB
16MB	1.0	0/13000028	0/13000198	OK				

The `Time` field for the merged backup displays the time required for the merge.

### Pinning Backups

If you need to keep certain backups longer than the established retention policy allows, you can pin them for arbitrary time. For example:

```

pg_probackup set-backup -B backup_dir --instance instance_name -i backup_id --ttl=30d

```

This command sets the expiration time of the specified backup to 30 days starting from the time indicated in its `recovery-time` attribute.

You can also explicitly set the expiration time for a backup using the `--expire-time` option. For example:

```

pg_probackup set-backup -B backup_dir --instance instance_name -i backup_id --expire-time="2020-01-01 00:00:00+03"

```

Alternatively, you can use the `--ttl` and `--expire-time` options with the `backup` command to pin the newly created backup:

```

pg_probackup backup -B backup_dir --instance instance_name -b FULL --ttl=30d
pg_probackup backup -B backup_dir --instance instance_name -b FULL --expire-time="2020-01-01 00:00:00+03"

```

To check if the backup is pinned, run the `show` command:

```
pg_probackup show -B backup_dir --instance instance_name -i backup_id
```

If the backup is pinned, it has the `expire-time` attribute that displays its expiration time:

```
...
recovery-time = '2017-05-16 12:57:31'
expire-time = '2020-01-01 00:00:00+03'
data-bytes = 22288792
...
```

You can unpin the backup by setting the `--ttl` option to zero:

```
pg_probackup set-backup -B backup_dir --instance instance_name -i backup_id --ttl=0
```

### Note

A pinned incremental backup implicitly pins all its parent backups. If you unpin such a backup later, its implicitly pinned parents will also be automatically unpinned.

### Configuring WAL Archive Retention Policy

When [continuous WAL archiving](#) is enabled, archived WAL segments can take a lot of disk space. Even if you delete old backup copies from time to time, the `--delete-wal` flag can purge only those WAL segments that do not apply to any of the remaining backups in the backup catalog. However, if point-in-time recovery is critical only for the most recent backups, you can configure WAL archive retention policy to keep WAL archive of limited depth and win back some more disk space.

To configure WAL archive retention policy, you have to run the `set-config` command with the `--wal-depth` option that specifies the number of backups that can be used for PITR. This setting applies to all the timelines, so you should be able to perform PITR for the same number of backups on each timeline, if available. [Pinned backups](#) are not included into this count: if one of the latest backups is pinned, `pg_probackup` ensures that PITR is possible for one extra backup.

To remove WAL segments that do not satisfy the defined WAL archive retention policy, you simply have to run the `delete` or `backup` command with the `--delete-wal` flag. For archive backups, WAL segments between `Start LSN` and `Stop LSN` are always kept intact, so such backups remain valid regardless of the `--wal-depth` setting and can still be restored, if required.

You can also use the `--wal-depth` option with the `delete` and `backup` commands to override the previously defined WAL archive retention policy and purge old WAL segments on the fly.

Suppose you have backed up the `node` instance in the `backup_dir` directory and configured [continuous WAL archiving](#):

```
pg_probackup show -B backup_dir --instance node
```

```
BACKUP INSTANCE 'node'
```

```
=====
Instance  Version  ID          Recovery Time          Mode  WAL Mode  TLI  Time  Data

32MB     1.00   0/3E000028 0/3F0000B8  OK
=====
```

## Additional Supplied Programs

```
node      11      PZ7YK2  2019-10-11 19:45:45+03  FULL  STREAM  1/0  11s  180MB
16MB     1.00  0/3C000028  0/3C000198  OK
node      11      PZ7YFO  2019-10-11 19:43:04+03  FULL  STREAM  1/0  10s  30MB
16MB     1.00  0/20000028  0/200ADD8  OK
```

You can check the state of the WAL archive by running the `show` command with the `--archive` flag:

```
pg_probackup show -B backup_dir --instance node --archive
```

```
ARCHIVE INSTANCE 'node'
```

```
=====
TLI Parent TLI  Switchpoint  Min Segno          Max Segno          N
segments Size  Zratio  N backups  Status
=====
1    0          0/0          000000010000000000000001  000000010000000000000047  71
      36MB  31.00   6          OK
```

WAL purge without `--wal-depth` cannot achieve much, only one segment is removed:

```
pg_probackup delete -B backup_dir --instance node --delete-wal
```

```
ARCHIVE INSTANCE 'node'
```

```
=====

segments Size  Zratio  N backups  Status
=====
1    0          0/0          000000010000000000000002  000000010000000000000047  70
      34MB  32.00   6          OK
```

If you would like, for example, to keep only those WAL segments that can be applied to the latest valid backup, set the `--wal-depth` option to 1:

```
pg_probackup delete -B backup_dir --instance node --delete-wal --wal-depth=1
```

```
ARCHIVE INSTANCE 'node'
```

```
=====
TLI Parent TLI  Switchpoint  Min Segno          Max Segno          N
segments Size  Zratio  N backups  Status
=====
1    0          0/0          000000010000000000000046  000000010000000000000047  2
      143kB  228.00  6          OK
```

Alternatively, you can use the `--wal-depth` option with the `backup` command:

```
pg_probackup backup -B backup_dir --instance node -b DELTA --wal-depth=1 --delete-wal
```

```
ARCHIVE INSTANCE 'node'
```

```
=====

      72kB  228.00  7          OK
```

## Merging Backups

As you take more and more incremental backups, the total size of the backup catalog can substantially grow. To save disk space, you can merge incremental backups to their parent full backup by running the `merge` command, specifying the backup ID of the most recent incremental backup you would like to merge:

```
pg_probackup merge -B backup_dir --instance instance_name -i backup_id
```

This command merges backups that belong to a common incremental backup chain. If you specify a full backup, it will be merged with its first incremental backup. If you specify an incremental backup,

it will be merged to its parent full backup, together with all incremental backups between them. Once the merge is complete, the full backup takes in all the merged data, and the incremental backups are removed as redundant. Thus, the merge operation is virtually equivalent to retaking a full backup and removing all the outdated backups, but it allows to save much time, especially for large data volumes, as well as I/O and network traffic if you are using `pg_probackup` in the `remote` mode.

Before the merge, `pg_probackup` validates all the affected backups to ensure that they are valid. You can check the current backup status by running the `show` command with the backup ID:

```
pg_probackup show -B backup_dir --instance instance_name -i backup_id
```

If the merge is still in progress, the backup status is displayed as `MERGING`. For full backups, it can also be shown as `MERGED` while the metadata is being updated at the final stage of the merge. The merge is idempotent, so you can restart the merge if it was interrupted.

## Deleting Backups

To delete a backup that is no longer required, run the following command:

```
pg_probackup delete -B backup_dir --instance instance_name -i backup_id
```

This command will delete the backup with the specified `backup_id`, together with all the incremental backups that descend from `backup_id`, if any. This way you can delete some recent incremental backups, retaining the underlying full backup and some of the incremental backups that follow it.

To delete obsolete WAL files that are not necessary to restore any of the remaining backups, use the `--delete-wal` flag:

```
pg_probackup delete -B backup_dir --instance instance_name --delete-wal
```

To delete backups that are expired according to the current retention policy, use the `--delete-expired` flag:

```
pg_probackup delete -B backup_dir --instance instance_name --delete-expired
```

Expired backups cannot be removed while at least one incremental backup that satisfies the retention policy is based on them. If you would like to minimize the number of backups still required to keep incremental backups valid, specify the `--merge-expired` flag when running this command:

```
pg_probackup delete -B backup_dir --instance instance_name --delete-expired --merge-expired
```

In this case, `pg_probackup` searches for the oldest incremental backup that satisfies the retention policy and merges this backup with the underlying full and incremental backups that have already expired, thus making it a full backup. Once the merge is complete, the remaining expired backups are deleted.

Before merging or deleting backups, you can run the `delete` command with the `--dry-run` flag, which displays the status of all the available backups according to the current retention policy, without performing any irreversible actions.

To delete all backups with specific status, use the `--status`:

```
pg_probackup delete -B backup_dir --instance instance_name --status=ERROR
```

Deleting backups by status ignores established retention policies.

## Cloning and Synchronizing Postgres Pro Instance

`pg_probackup` can create a copy of a Postgres Pro instance directly, without using the backup catalog. To do this, you can run the `catchup` command. It can be useful in the following cases:

- To add a new standby server.

Usually, [pg\\_basebackup](#) is used to create a copy of a Postgres Pro instance. If the data directory of the destination instance is empty, the `catchup` command works similarly, but it can be faster if run in parallel mode.

- To have a fallen-behind standby server “catch up” with master.

Under write-intensive load, replicas may fail to replay WAL fast enough to keep up with master and hence may lag behind. A usual solution to create a new replica and switch to it requires a lot of extra space and data transfer. The `catchup` command allows you to update an existing replica much faster by bringing differences from master.

`catchup` is different from other `pg_probackup` operations:

- The backup catalog is not required.
- STREAM WAL delivery mode is only supported.
- Copying external directories is not supported.
- DDL commands [CREATE TABLESPACE/DROP TABLESPACE](#) cannot be run simultaneously with `catchup`.
- `catchup` takes configuration files, such as `postgresql.conf`, `postgresql.auto.conf`, or `pg_hba.conf`, from the source server and overwrites them on the target server. The `--exclude-path` option allows you to keep the configuration files intact.

To prepare for cloning/synchronizing a Postgres Pro instance, set up the source instance server as follows:

- [Configure the database cluster](#) for the instance to copy.
- To copy from a remote server, [configure the remote mode](#).
- To use the PTRACK `catchup` mode, [set up PTRACK backups](#).

Before cloning/synchronizing a Postgres Pro instance, ensure that the source instance server is running and accepting connections. To clone/sync a Postgres Pro instance, on the server with the destination instance, you can run the `catchup` command as follows:

```
pg_probackup catchup -b catchup_mode --source-pgdata=path_to_pgdata_on_remote_server --
destination-pgdata=path_to_local_dir --stream [connection_options] [remote_options]
```

Where `catchup_mode` can take one of the following values: FULL, DELTA, or PTRACK.

- FULL — creates a full copy of the Postgres Pro instance. The data directory of the destination instance must be empty for this mode.
- DELTA — reads all data files in the data directory and creates an incremental copy for pages that have changed since the destination instance was shut down.
- PTRACK — tracking page changes on the fly, only reads and copies pages that have changed since the point of divergence of the source and destination instances.

### Warning

PTRACK `catchup` mode requires PTRACK not earlier than 2.0 and hence, Postgres Pro not earlier than 11.

By specifying the `--stream` option, you can set [STREAM](#) WAL delivery mode of copying, which will include all the necessary WAL files by streaming them from the instance server via replication protocol.

You can use [connection\\_options](#) to specify the connection to the source database cluster. If it is located on a different server, also specify [remote\\_options](#).

If the source database cluster contains tablespaces that must be located in a different directory, additionally specify the `--tablespace-mapping` option:

```
pg_probackup catchup -b catchup_mode --source-pgdata=path_to_pgdata_on_remote_server --
destination-pgdata=path_to_local_dir --stream --tablespace-mapping=OLDDIR=NEWDIR
```

To run the `catchup` command on parallel threads, specify the number of threads with the `--threads` option:

```
pg_probackup catchup -b catchup_mode --source-pgdata=path_to_pgdata_on_remote_server --
destination-pgdata=path_to_local_dir --stream --threads=num_threads
```

Before cloning/synchronising a Postgres Pro instance, you can run the `catchup` command with the `--dry-run` flag to estimate the size of data files to be transferred, but make no changes on disk:

```
pg_probackup catchup -b catchup_mode --source-pgdata=path_to_pgdata_on_remote_server --
destination-pgdata=path_to_local_dir --stream --dry-run
```

For example, assume that a remote standby server with the Postgres Pro instance having `/replica-pgdata` data directory has fallen behind. To sync this instance with the one in `/master-pgdata` data directory, you can run the `catchup` command in the `PTRACK` mode on four parallel threads as follows:

```
pg_probackup catchup --source-pgdata=/master-pgdata --destination-pgdata=/replica-
pgdata -p 5432 -d postgres -U remote-postgres-user --stream --backup-mode=PTRACK
--remote-host=remote-hostname --remote-user=remote-unix-username -j 4 --exclude-
path=postgresql.conf --exclude-path=postgresql.auto.conf --exclude-path=pg_hba.conf --
exclude-path=pg_ident.conf
```

Note that in this example, the configuration files will not be overwritten during synchronization.

Another example shows how you can add a new remote standby server with the Postgres Pro data directory `/replica-pgdata` by running the `catchup` command in the `FULL` mode on four parallel threads:

```
pg_probackup catchup --source-pgdata=/master-pgdata --destination-pgdata=/replica-
pgdata -p 5432 -d postgres -U remote-postgres-user --stream --backup-mode=FULL --
remote-host=remote-hostname --remote-user=remote-unix-username -j 4
```

## Command-Line Reference

### Commands

This section describes `pg_probackup` commands. Optional parameters are enclosed in square brackets. For detailed parameter descriptions, see the section [Options](#).

#### version

```
pg_probackup version
```

Prints `pg_probackup` version.

#### help

```
pg_probackup help [command]
```

Displays the synopsis of `pg_probackup` commands. If one of the `pg_probackup` commands is specified, shows detailed information about the options that can be used with this command.

#### init

```
pg_probackup init -B backup_dir [--help]
```

Initializes the backup catalog in `backup_dir` that will store backup copies, WAL archive, and meta information for the backed up database clusters. If the specified `backup_dir` already exists, it must be empty. Otherwise, `pg_probackup` displays a corresponding error message.

For details, see the section [Initializing the Backup Catalog](#).

**add-instance**

```
pg_probackup add-instance -B backup_dir -D data_dir --instance instance_name [--help]
```

Initializes a new backup instance inside the backup catalog *backup\_dir* and generates the `pg_probackup.conf` configuration file that controls `pg_probackup` settings for the cluster with the specified *data\_dir* data directory.

For details, see the section [Adding a New Backup Instance](#).

**del-instance**

```
pg_probackup del-instance -B backup_dir --instance instance_name [--help]
```

Deletes all backups and WAL files associated with the specified instance.

**set-config**

```
pg_probackup set-config -B backup_dir --instance instance_name
[--help] [--pgdata=pgdata-path]
[--retention-redundancy=redundancy] [--retention-window=window] [--wal-depth=wal_depth]
[--compress-algorithm=compression_algorithm] [--compress-level=compression_level]
[-d dbname] [-h host] [-p port] [-U username]
[--archive-timeout=timeout] [--external-dirs=external_directory_path]
[--restore-command=cmdline]
[remote_options] [remote_wal_archive_options] [logging_options]
```

Adds the specified connection, compression, retention, logging, and external directory settings into the `pg_probackup.conf` configuration file, or modifies the previously defined values.

For all available settings, see the [Options](#) section.

It is **not recommended** to edit `pg_probackup.conf` manually.

**set-backup**

```
pg_probackup set-backup -B backup_dir --instance instance_name -i backup_id
{--ttl=ttl | --expire-time=time}
[--note=backup_note] [--help]
```

Sets the provided backup-specific settings into the `backup.control` configuration file, or modifies the previously defined values.

```
--note=backup_note
```

Sets the text note for backup copy. If *backup\_note* contain newline characters, then only substring before first newline character will be saved. Max size of text note is 1 KB. The 'none' value removes current note.

For all available pinning settings, see the section [Pinning Options](#).

**show-config**

```
pg_probackup show-config -B backup_dir --instance instance_name [--format=plain|json]
```

Displays the contents of the `pg_probackup.conf` configuration file located in the `backup_dir/backups/instance_name` directory. You can specify the `--format=json` option to get the result in the JSON format. By default, configuration settings are shown as plain text.

To edit `pg_probackup.conf`, use the [set-config](#) command.

**show**

```
pg_probackup show -B backup_dir
[--help] [--instance instance_name [-i backup_id | --archive]] [--format=plain|json]
[--no-color]
```

Shows the contents of the backup catalog. If *instance\_name* and *backup\_id* are specified, shows detailed information about this backup. If the `--archive` option is specified, shows the contents of WAL archive of the backup catalog.

By default, the contents of the backup catalog is shown as plain text. You can specify the `--format=json` option to get the result in the JSON format. If `--no-color` flag is used, then the output is not colored.

For details on usage, see the sections [Managing the Backup Catalog](#) and [Viewing WAL Archive Information](#).

## backup

```
pg_probackup backup -B backup_dir -b backup_mode --instance instance_name
[--help] [-j num_threads] [--progress]
[-C] [--stream [-S slot_name] [--temp-slot]] [--backup-pg-log]
[--no-validate] [--skip-block-validation]
[-w --no-password] [-W --password]
[--archive-timeout=timeout] [--external-dirs=external_directory_path]
[--no-sync] [--note=backup_note]
[connection_options] [compression_options] [remote_options]
[retention_options] [pinning_options] [logging_options]
```

Creates a backup copy of the Postgres Pro instance.

`-b mode`

`--backup-mode=mode`

Specifies the backup mode to use. Possible values are:

- **FULL** — creates a full backup that contains all the data files of the cluster to be restored.
- **DELTA** — reads all data files in the data directory and creates an incremental backup for pages that have changed since the previous backup.
- **PAGE** — creates an incremental PAGE backup based on the WAL files that have changed since the previous full or incremental backup was taken.
- **PTRACK** — creates an incremental PTRACK backup tracking page changes on the fly.

`-C`

`--smooth-checkpoint`

Spreads out the checkpoint over a period of time. By default, `pg_probackup` tries to complete the checkpoint as soon as possible.

`--stream`

Makes a **STREAM** backup, which includes all the necessary WAL files by streaming them from the database server via replication protocol.

`--temp-slot`

Creates a temporary physical replication slot for streaming WAL from the backed up Postgres Pro instance. It ensures that all the required WAL segments remain available if WAL is rotated while the backup is in progress. This flag can only be used together with the `--stream` flag. The default slot name is `pg_probackup_slot`, which can be changed using the `--slot/-S` option.

`-S slot_name`

`--slot=slot_name`

Specifies the replication slot for WAL streaming. This option can only be used together with the `--stream` flag.

`--backup-pg-log`

Includes the log directory into the backup. This directory usually contains log messages. By default, log directory is excluded.

```
-E external_directory_path
--external-dirs=external_directory_path
```

Includes the specified directory into the backup by recursively copying its contents into a separate subdirectory in the backup catalog. This option is useful to back up scripts, SQL dump files, and configuration files located outside of the data directory. If you would like to back up several external directories, separate their paths by a colon on Unix and a semicolon on Windows.

```
--archive-timeout=wait_time
```

Sets the timeout for WAL segment archiving and streaming, in seconds. By default, `pg_probackup` waits 300 seconds.

```
--skip-block-validation
```

Disables block-level checksum verification to speed up the backup process.

```
--no-validate
```

Skips automatic validation after the backup is taken. You can use this flag if you validate backups regularly and would like to save time when running backup operations.

```
--no-sync
```

Do not sync backed up files to disk. You can use this flag to speed up the backup process. Using this flag can result in data corruption in case of operating system or hardware crash. If you use this option, it is recommended to run the `validate` command once the backup is complete to detect possible issues.

```
--note=backup_note
```

Sets the text note for backup copy. If *backup\_note* contain newline characters, then only substring before first newline character will be saved. Max size of text note is 1 KB. The `'none'` value removes current note.

Additionally, [connection options](#), [retention options](#), [pinning options](#), [remote mode options](#), [compression options](#), [logging options](#), and [common options](#) can be used.

For details on usage, see the section [Creating a Backup](#).

## restore

```
pg_probackup restore -B backup_dir --instance instance_name
[--help] [-D data_dir] [-i backup_id]
[-j num_threads] [--progress]
[-T OLDDIR=NEWDIR] [--external-mapping=OLDDIR=NEWDIR] [--skip-external-dirs]
[-R | --restore-as-replica] [--no-validate] [--skip-block-validation]
[--force] [--no-sync]
[--restore-command=cmdline]
[--primary-conninfo=primary_conninfo]
[-S | --primary-slot-name=slot_name]
[recovery_target_options] [logging_options] [remote_options]
[partial_restore_options] [remote_wal_archive_options]
```

Restores the Postgres Pro instance from a backup copy located in the *backup\_dir* backup catalog. If you specify a [recovery target option](#), `pg_probackup` finds the closest backup and restores it to the specified recovery target. If neither the backup ID nor recovery target options are provided, `pg_probackup` uses the most recent backup to perform the recovery.

```
-R
--restore-as-replica
```

Creates a minimal recovery configuration file to facilitate setting up a standby server. If the replication connection requires a password, you must specify the password manually in the [primary\\_conninfo](#) parameter as it is not included. For Postgres Pro 11 or lower, recovery settings

are written into the `recovery.conf` file. Starting from Postgres Pro 12, `pg_probackup` writes these settings into the `probackup_recovery.conf` file in the data directory, and then includes them into the `postgresql.auto.conf` when the cluster is started.

`--primary-conninfo=primary_conninfo`

Sets the `primary_conninfo` parameter to the specified value. This option will be ignored unless the `-R` flag is specified.

**Example:** `--primary-conninfo="host=192.168.1.50 port=5432 user=foo password=foopass"`

`-S`

`--primary-slot-name=slot_name`

Sets the `primary_slot_name` parameter to the specified value. This option will be ignored unless the `-R` flag is specified.

`-T OLDDIR=NEWDIR`

`--tablespace-mapping=OLDDIR=NEWDIR`

Relocates the tablespace from the `OLDDIR` to the `NEWDIR` directory at the time of recovery. Both `OLDDIR` and `NEWDIR` must be absolute paths. If the path contains the equals sign (`=`), escape it with a backslash. This option can be specified multiple times for multiple tablespaces.

`--external-mapping=OLDDIR=NEWDIR`

Relocates an external directory included into the backup from the `OLDDIR` to the `NEWDIR` directory at the time of recovery. Both `OLDDIR` and `NEWDIR` must be absolute paths. If the path contains the equals sign (`=`), escape it with a backslash. This option can be specified multiple times for multiple directories.

`--skip-external-dirs`

Skip external directories included into the backup with the `--external-dirs` option. The contents of these directories will not be restored.

`--skip-block-validation`

Disables block-level checksum verification to speed up validation. During automatic validation before the restore only file-level checksums will be verified.

`--no-validate`

Skips backup validation. You can use this flag if you validate backups regularly and would like to save time when running restore operations.

`--restore-command=cmdline`

Sets the `restore_command` parameter to the specified command. For example: `--restore-command='cp /mnt/server/archivedir/%f "%p"'`

`--force`

Allows to ignore an invalid status of the backup. You can use this flag if you need to restore the Postgres Pro cluster from a corrupt or an invalid backup. Use with caution. If `PGDATA` contains a non-empty directory with system ID different from that of the backup being restored, `incremental restore` with this flag overwrites the directory contents (while an error occurs without the flag). If tablespaces are remapped through the `--tablespace-mapping` option into non-empty directories, the contents of such directories will be deleted.

`--no-sync`

Do not sync restored files to disk. You can use this flag to speed up restore process. Using this flag can result in data corruption in case of operating system or hardware crash. If it happens, you have to run the `restore` command again.

Additionally, [recovery target options](#), [remote mode options](#), [remote WAL archive options](#), [logging options](#), [partial restore options](#), and [common options](#) can be used.

For details on usage, see the section [Restoring a Cluster](#).

### checkdb

```
pg_probackup checkdb
[-B backup_dir] [--instance instance_name] [-D data_dir]
[--help] [-j num_threads] [--progress]
[--amcheck [--skip-block-validation] [--checkunique] [--heapallindexed]]
[connection_options] [logging_options]
```

Verifies the Postgres Pro database cluster correctness by detecting physical and logical corruption.

#### --amcheck

Performs logical verification of indexes for the specified Postgres Pro instance if no corruption was found while checking data files. You must have the [amcheck](#) extension or the `amcheck_next` extension installed in the database to check its indexes. For databases without `amcheck`, index verification will be skipped. Additional options `--checkunique` and `--heapallindexed` are effective depending on the version of `amcheck` installed.

#### --checkunique

Verifies unique constraints during logical verification of indexes. You can use this flag only together with the `--amcheck` flag when the `amcheck` extension is installed in the database.

The verification of unique constraints is only possible if in the version of the `amcheck` extension you are using, the `bt_index_check` function takes the `checkunique` parameter.

#### --heapallindexed

Checks that all heap tuples that should be indexed are actually indexed. You can use this flag only together with the `--amcheck` flag.

This check is only possible if in the version of the `amcheck/amcheck_next` extension you are using, the `bt_index_check` function takes the `heapallindexed` parameter.

#### --skip-block-validation

Skip validation of data files. You can use this flag only together with the `--amcheck` flag, so that only logical verification of indexes is performed.

Additionally, [connection options](#) and [logging options](#) can be used.

For details on usage, see the section [Verifying a Cluster](#).

### validate

```
pg_probackup validate -B backup_dir
[--help] [--instance instance_name] [-i backup_id]
[-j num_threads] [--progress]
[--skip-block-validation]
[recovery_target_options] [logging_options]
```

Verifies that all the files required to restore the cluster are present and are not corrupt. If `instance_name` is not specified, `pg_probackup` validates all backups available in the backup catalog. If you specify the `instance_name` without any additional options, `pg_probackup` validates all the backups available for this backup instance. If you specify the `instance_name` with a [recovery target option](#) and/or a `backup_id`, `pg_probackup` checks whether it is possible to restore the cluster using these options.

For details, see the section [Validating a Backup](#).

**merge**

```
pg_probackup merge -B backup_dir --instance instance_name -i backup_id
[--help] [-j num_threads] [--progress] [--no-validate] [--no-sync]
[logging_options]
```

Merges backups that belong to a common incremental backup chain. If you specify a full backup, it will be merged with its first incremental backup. If you specify an incremental backup, it will be merged to its parent full backup, together with all incremental backups between them. Once the merge is complete, the full backup takes in all the merged data, and the incremental backups are removed as redundant.

`--no-validate`

Skips automatic validation before and after merge.

`--no-sync`

Do not sync merged files to disk. You can use this flag to speed up the merge process. Using this flag can result in data corruption in case of operating system or hardware crash.

For details, see the section [Merging Backups](#).

**delete**

```
pg_probackup delete -B backup_dir --instance instance_name
[--help] [-j num_threads] [--progress]
[--retention-redundancy=redundancy] [--retention-window=window] [--wal-depth=wal_depth]
[--delete-wal]
{-i backup_id | --delete-expired [--merge-expired] | --merge-expired | --
status=backup_status}
[--dry-run] [--no-validate] [--no-sync] [logging_options]
```

Deletes backup with specified *backup\_id* or launches the retention purge of backups and archived WAL that do not satisfy the current retention policies.

`--no-validate`

Skips automatic validation before and after retention merge.

`--no-sync`

Do not sync merged files to disk. You can use this flag to speed up the retention merge process. Using this flag can result in data corruption in case of operating system or hardware crash.

For details, see the sections [Deleting Backups](#), [Retention Options](#), and [Configuring Retention Policy](#).

**archive-push**

```
pg_probackup archive-push -B backup_dir --instance instance_name
--wal-file-name=wal_file_name [--wal-file-path=wal_file_path]
[--help] [--no-sync] [--compress] [--no-ready-rename] [--overwrite]
[-j num_threads] [--batch-size=batch_size]
[--archive-timeout=timeout]
[--compress-algorithm=compression_algorithm]
[--compress-level=compression_level]
[remote_options] [logging_options]
```

Copies WAL files into the corresponding subdirectory of the backup catalog and validates the backup instance by *instance\_name* and `system-identifier`. If parameters of the backup instance and the cluster do not match, this command fails with the following error message: `Refuse to push WAL segment segment_name into archive. Instance parameters mismatch.`

If the files to be copied already exists in the backup catalog, `pg_probackup` computes and compares their checksums. If the checksums match, `archive-push` skips the corresponding file and returns a successful

execution code. Otherwise, `archive-push` fails with an error. If you would like to replace WAL files in the case of checksum mismatch, run the `archive-push` command with the `--overwrite` flag.

Each file is copied to a temporary file with the `.part` suffix. If the temporary file already exists, `pg_probackup` will wait `archive_timeout` seconds before discarding it. After the copy is done, atomic rename is performed. This algorithm ensures that a failed `archive-push` will not stall continuous archiving and that concurrent archiving from multiple sources into a single WAL archive has no risk of archive corruption.

To speed up archiving, you can specify the `--batch-size` option to copy WAL segments in batches of the specified size. If `--batch-size` option is used, then you can also specify the `-j` option to copy the batch of WAL segments on multiple threads.

WAL segments copied to the archive are synced to disk unless the `--no-sync` flag is used.

You can use `archive-push` in the `archive_command` Postgres Pro parameter to set up [continuous WAL archiving](#).

For details, see sections [Archiving Options](#) and [Compression Options](#).

#### **archive-get**

```
pg_probackup archive-get -B backup_dir --instance instance_name --wal-file-  
path=wal_file_path --wal-file-name=wal_file_name  
[-j num_threads] [--batch-size=batch_size]  
[--prefetch-dir=prefetch_dir_path] [--no-validate-wal]  
[--help] [remote_options] [logging_options]
```

Copies WAL files from the corresponding subdirectory of the backup catalog to the cluster's write-ahead log location. This command is automatically set by `pg_probackup` as part of the `restore_command` when restoring backups using a WAL archive. You do not need to set it manually.

To speed up recovery, you can specify the `--batch-size` option to copy WAL segments in batches of the specified size. If `--batch-size` option is used, then you can also specify the `-j` option to copy the batch of WAL segments on multiple threads.

For details, see section [Archiving Options](#).

#### **catchup**

```
pg_probackup catchup -b catchup_mode  
--source-pgdata=path_to_pgdata_on_remote_server  
--destination-pgdata=path_to_local_dir  
[--help] [-j | --threads=num_threads] [--stream] [--dry-run]  
[--temp-slot] [-P | --perm-slot] [-S | --slot=slot_name]  
[--exclude-path=PATHNAME]  
[-T OLDDIR=NEWDIR]  
[connection_options] [remote_options]
```

Creates a copy of a Postgres Pro instance without using the backup catalog.

```
-b catchup_mode  
--backup-mode=catchup_mode
```

Specifies the catchup mode to use. Possible values are:

- `FULL` — creates a full copy of the Postgres Pro instance.
- `DELTA` — reads all data files in the data directory and creates an incremental copy for pages that have changed since the destination instance was shut down.
- `PTRACK` — tracking page changes on the fly, only reads and copies pages that have changed since the point of divergence of the source and destination instances.

**Warning**

PTRACK catchup mode requires PTRACK not earlier than 2.0 and hence, Postgres Pro not earlier than 11.

`--source-pgdata=path_to_pgdata_on_remote_server`

Specifies the path to the data directory of the instance to be copied. The path can be local or remote.

`--destination-pgdata=path_to_local_dir`

Specifies the path to the local data directory to copy to.

`-j num_threads`

`--threads=num_threads`

Sets the number of parallel threads for `catchup` process.

`--stream`

Copies the instance in **STREAM** WAL delivery mode, including all the necessary WAL files by streaming them from the instance server via replication protocol.

`--dry-run`

Displays the total size of the files to be transferred by `catchup`. This flag initiates a trial run of `catchup`, which does not actually create, delete or move files on disk. WAL streaming is skipped with `--dry-run`. This flag also allows you to check that all the options are correct and cloning/synchronising is ready to run.

`-x=path_prefix`

`--exclude-path=path_prefix`

Specifies a prefix for files to exclude from the synchronization of Postgres Pro instances during copying. The prefix must contain a path relative to the data directory of an instance. If the prefix specifies a directory, all files in this directory will not be synchronized.

**Warning**

This option is dangerous since excluding files from synchronization can result in incomplete synchronization; use with care.

`--temp-slot`

Creates a *temporary* physical replication slot for streaming WAL from the Postgres Pro instance being copied. It ensures that all the required WAL segments remain available if WAL is rotated while the backup is in progress. This flag can only be used together with the `--stream` flag and cannot be used together with the `--perm-slot` flag. The default slot name is `pg_probackup_slot`, which can be changed using the `--slot/-S` option.

`-P`

`--perm-slot`

Creates a *permanent* physical replication slot for streaming WAL from the Postgres Pro instance being copied. This flag can only be used together with the `--stream` flag and cannot be used together with the `--temp-slot` flag. The default slot name is `pg_probackup_perm_slot`, which can be changed using the `--slot/-S` option.

```
-S slot_name
--slot=slot_name
```

Specifies the replication slot for WAL streaming. This option can only be used together with the `--stream` flag.

```
-T OLDDIR=NEWDIR
--tablespace-mapping=OLDDIR=NEWDIR
```

Relocates the tablespace from the *OLDDIR* to the *NEWDIR* directory at the time of recovery. Both *OLDDIR* and *NEWDIR* must be absolute paths. If the path contains the equals sign (=), escape it with a backslash. This option can be specified multiple times for multiple tablespaces.

Additionally, [connection options](#), [remote mode options](#) can be used.

For details on usage, see the section [Cloning and Synchronizing Postgres Pro Instance](#).

## Options

This section describes command-line options for `pg_probackup` commands. If the option value can be derived from an environment variable, this variable is specified below the command-line option, in the uppercase. Some values can be taken from the `pg_probackup.conf` configuration file located in the backup catalog.

For details, see [the section called "Configuring pg\\_probackup"](#).

If an option is specified using more than one method, command-line input has the highest priority, while the `pg_probackup.conf` settings have the lowest priority.

## Common Options

The list of general options.

```
-B directory
--backup-path=directory
BACKUP_PATH
```

Specifies the absolute path to the backup catalog. Backup catalog is a directory where all backup files and meta information are stored. Since this option is required for most of the `pg_probackup` commands, you are recommended to specify it once in the `BACKUP_PATH` environment variable. In this case, you do not need to use this option each time on the command line.

```
-D directory
--pgdata=directory
PGDATA
```

Specifies the absolute path to the data directory of the database cluster. This option is mandatory only for the [add-instance](#) command. Other commands can take its value from the `PGDATA` environment variable, or from the `pg_probackup.conf` configuration file.

```
-i backup_id
--backup-id=backup_id
```

Specifies the unique identifier of the backup.

```
-j num_threads
--threads=num_threads
```

Sets the number of parallel threads for backup, restore, merge, validate, checkdb, and archive-push processes.

```
--progress
```

Shows the progress of operations.

`--help`

Shows detailed information about the options that can be used with this command.

### Recovery Target Options

If [continuous WAL archiving](#) is configured, you can use one of these options together with [restore](#) or [validate](#) commands to specify the moment up to which the database cluster must be restored or validated.

`--recovery-target=immediate|latest`

Defines when to stop the recovery:

- The `immediate` value stops the recovery after reaching the consistent state of the specified backup, or the latest available backup if the `-i/--backup-id` option is omitted. This is the default behavior for STREAM backups.
- The `latest` value continues the recovery until all WAL segments available in the archive are applied. This is the default behavior for ARCHIVE backups.

`--recovery-target-timeline=timeline`

Specifies a particular timeline to be used for recovery. By default, the timeline of the specified backup is used.

`--recovery-target-lsn=lsn`

Specifies the LSN of the write-ahead log location up to which recovery will proceed. Can be used only when restoring a database cluster of major version 10 or higher.

`--recovery-target-name=recovery_target_name`

Specifies a named savepoint up to which to restore the cluster.

`--recovery-target-time=time`

Specifies the timestamp up to which recovery will proceed. If the time zone offset is not specified, the local time zone is used.

Example: `--recovery-target-time="2020-01-01 00:00:00+03"`

`--recovery-target-xid=xid`

Specifies the transaction ID up to which recovery will proceed.

`--recovery-target-inclusive=boolean`

Specifies whether to stop just after the specified recovery target (`true`), or just before the recovery target (`false`). This option can only be used together with `--recovery-target-name`, `--recovery-target-time`, `--recovery-target-lsn` or `--recovery-target-xid` options. The default depends on the [recovery\\_target\\_inclusive](#) parameter.

`--recovery-target-action=pause|promote|shutdown`

Specifies [recovery\\_target\\_action](#) the server should take when the recovery target is reached.

Default: `pause`

### Retention Options

You can use these options together with [backup](#) and [delete](#) commands.

For details on configuring retention policy, see the section [Configuring Retention Policy](#).

`--retention-redundancy=redundancy`

Specifies the number of full backup copies to keep in the data directory. Must be a non-negative integer. The zero value disables this setting.

Default: 0

`--retention-window=window`

Number of days of recoverability. Must be a non-negative integer. The zero value disables this setting.

Default: 0

`--wal-depth=wal_depth`

Number of latest valid backups on every timeline that must retain the ability to perform PITR. Must be a non-negative integer. The zero value disables this setting.

Default: 0

`--delete-wal`

Deletes WAL files that are no longer required to restore the cluster from any of the existing backups.

`--delete-expired`

Deletes backups that do not conform to the retention policy defined in the `pg_probackup.conf` configuration file.

`--merge-expired`

Merges the oldest incremental backup that satisfies the requirements of retention policy with its parent backups that have already expired.

`--dry-run`

Displays the current status of all the available backups, without deleting or merging expired backups, if any.

### Pinning Options

You can use these options together with [backup](#) and [set-backup](#) commands.

For details on backup pinning, see the section [Backup Pinning](#).

`--ttl=ttd`

Specifies the amount of time the backup should be pinned. Must be a non-negative integer. The zero value unpins the already pinned backup. Supported units: ms, s, min, h, d (s by default).

Example: `--ttl=30d`

`--expire-time=time`

Specifies the timestamp up to which the backup will stay pinned. Must be an ISO-8601 complaint timestamp. If the time zone offset is not specified, the local time zone is used.

Example: `--expire-time="2020-01-01 00:00:00+03"`

### Logging Options

You can use these options with any command.

`--no-color`

Disable coloring for console log messages of `warning` and `error` levels.

`--log-level-console=log_level`

Controls which message levels are sent to the console log. Valid values are `verbose`, `log`, `info`, `warning`, `error` and `off`. Each level includes all the levels that follow it. The later the level, the fewer messages are sent. The `off` level disables console logging.

Default: `info`

### Note

All console log messages are going to `stderr`, so the output of `show` and `show-config` commands does not mingle with log messages.

`--log-level-file=log_level`

Controls which message levels are sent to a log file. Valid values are `verbose`, `log`, `info`, `warning`, `error`, and `off`. Each level includes all the levels that follow it. The later the level, the fewer messages are sent. The `off` level disables file logging.

Default: `off`

`--log-filename=log_filename`

Defines the filenames of the created log files. The filenames are treated as a `strftime` pattern, so you can use %-escapes to specify time-varying filenames.

Default: `pg_probackup.log`

For example, if you specify the `pg_probackup-%u.log` pattern, `pg_probackup` generates a separate log file for each day of the week, with `%u` replaced by the corresponding decimal number: `pg_probackup-1.log` for Monday, `pg_probackup-2.log` for Tuesday, and so on.

This option takes effect if file logging is enabled by the `--log-level-file` option.

`--error-log-filename=error_log_filename`

Defines the filenames of log files for error messages only. The filenames are treated as a `strftime` pattern, so you can use %-escapes to specify time-varying filenames.

Default: `none`

For example, if you specify the `error-pg_probackup-%u.log` pattern, `pg_probackup` generates a separate log file for each day of the week, with `%u` replaced by the corresponding decimal number: `error-pg_probackup-1.log` for Monday, `error-pg_probackup-2.log` for Tuesday, and so on.

This option is useful for troubleshooting and monitoring.

`--log-directory=log_directory`

Defines the directory in which log files will be created. You must specify the absolute path. This directory is created lazily, when the first log message is written.

Default: `$BACKUP_PATH/log/`

`--log-rotation-size=log_rotation_size`

Maximum size of an individual log file. If this value is reached, the log file is rotated once a `pg_probackup` command is launched, except `help` and `version` commands. The zero value disables size-based rotation. Supported units: `kB`, `MB`, `GB`, `TB` (`kB` by default).

Default: `0`

`--log-rotation-age=log_rotation_age`

Maximum lifetime of an individual log file. If this value is reached, the log file is rotated once a `pg_probackup` command is launched, except `help` and `version` commands. The time of the last log file creation is stored in `$BACKUP_PATH/log/log_rotation`. The zero value disables time-based rotation. Supported units: `ms`, `s`, `min`, `h`, `d` (`min` by default).

Default: 0

### Connection Options

You can use these options together with [backup](#), [catchup](#), and [checkdb](#) commands.

All [libpq environment variables](#) are supported.

`-d dbname`  
`--pgdatabase=dbname`  
PGDATABASE

Specifies the name of the database to connect to. The connection is used only for managing backup process, so you can connect to any existing database. If this option is not provided on the command line, PGDATABASE environment variable, or the `pg_probackup.conf` configuration file, `pg_probackup` tries to take this value from the PGUSER environment variable, or from the current user name if PGUSER variable is not set.

`-h host`  
`--pghost=host`  
PGHOST

Specifies the host name of the system on which the server is running. If the value begins with a slash, it is used as a directory for the Unix domain socket.

Default: localhost

`-p port`  
`--pgport=port`  
PGPORT

Specifies the TCP port or the local Unix domain socket file extension on which the server is listening for connections.

Default: 5432

`-U username`  
`--pguser=username`  
PGUSER

User name to connect as.

`-w`  
`--no-password`

Disables a password prompt. If the server requires password authentication and a password is not available by other means such as a [.pgpass](#) file or PGPASSWORD environment variable, the connection attempt will fail. This flag can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`  
`--password`

Forces a password prompt. (Deprecated)

### Compression Options

You can use these options together with [backup](#) and [archive-push](#) commands.

`--compress-algorithm=compression_algorithm`

Defines the algorithm to use for compressing data files. Possible values are `zlib`, `pglz`, and `none`. If set to `zlib` or `pglz`, this option enables compression. By default, compression is disabled. For the [archive-push](#) command, the `pglz` compression algorithm is not supported.

Default: none

`--compress-level=compression_level`

Defines compression level (0 through 9, 0 being no compression and 9 being best compression). This option can be used together with the `--compress-algorithm` option.

Default: 1

`--compress`

Alias for `--compress-algorithm=zlib` and `--compress-level=1`.

### Archiving Options

These options can be used with the [archive-push](#) command in the `archive_command` setting and the [archive-get](#) command in the `restore_command` setting.

Additionally, [remote mode options](#) and [logging options](#) can be used.

`--wal-file-path=wal_file_path`

Provides the path to the WAL file in `archive_command` and `restore_command`. Use the `%p` variable as the value for this option or explicitly specify the path to a file outside of the data directory. If you skip this option, the path specified in `pg_probackup.conf` will be used.

`--wal-file-name=wal_file_name`

Provides the name of the WAL file in `archive_command` and `restore_command`. Use the `%f` variable as the value for this option for correct processing. If the value of `--wal-file-path` is a path outside of the data directory, explicitly specify the filename.

`--overwrite`

Overwrites archived WAL file. Use this flag together with the [archive-push](#) command if the specified subdirectory of the backup catalog already contains this WAL file and it needs to be replaced with its newer copy. Otherwise, `archive-push` reports that a WAL segment already exists, and aborts the operation. If the file to replace has not changed, `archive-push` skips this file regardless of the `--overwrite` flag.

`--batch-size=batch_size`

Sets the maximum number of files that can be copied into the archive by a single `archive-push` process, or from the archive by a single `archive-get` process.

`--archive-timeout=wait_time`

Sets the timeout for considering existing `.part` files to be stale. By default, `pg_probackup` waits 300 seconds. This option can be used only with [archive-push](#) command.

`--no-ready-rename`

Do not rename status files in the `archive_status` directory. This option should be used only if `archive_command` contains multiple commands. This option can be used only with [archive-push](#) command.

`--no-sync`

Do not sync copied WAL files to disk. You can use this flag to speed up archiving process. Using this flag can result in WAL archive corruption in case of operating system or hardware crash. This option can be used only with [archive-push](#) command.

`--prefetch-dir=path`

Directory used to store prefetched WAL segments if `--batch-size` option is used. Directory must be located on the same filesystem and on the same mountpoint the `PGDATA/pg_wal` is located. By

default files are stored in `PGDATA/pg_wal/pbk_prefetch` directory. This option can be used only with [archive-get](#) command.

`--no-validate-wal`

Do not validate prefetched WAL file before using it. Use this option if you want to increase the speed of recovery. This option can be used only with [archive-get](#) command.

### Remote Mode Options

This section describes the options related to running `pg_probackup` operations remotely via SSH. These options can be used with [add-instance](#), [set-config](#), [backup](#), [catchup](#), [restore](#), [archive-push](#), and [archive-get](#) commands.

For details on configuring and using the remote mode, see [the section called “Configuring the Remote Mode”](#) and [the section called “Using pg\\_probackup in the Remote Mode”](#).

`--remote-proto=proto`

Specifies the protocol to use for remote operations. Currently only the SSH protocol is supported. Possible values are:

- `ssh` enables the remote mode via SSH. This is the default value.
- `none` explicitly disables the remote mode.

You can omit this option if the `--remote-host` option is specified.

`--remote-host=destination`

Specifies the remote host IP address or hostname to connect to.

`--remote-port=port`

Specifies the remote host port to connect to.

Default: 22

`--remote-user=username`

Specifies remote host user for SSH connection. If you omit this option, the current user initiating the SSH connection is used.

`--remote-path=path`

Specifies `pg_probackup` installation directory on the remote system.

`--ssh-options=ssh_options`

Provides a string of SSH command-line options. For example, the following options can be used to set `keep-alive` for SSH connections opened by `pg_probackup`: `--ssh-options="-o ServerAliveCountMax=5 -o ServerAliveInterval=60"`. For the full list of possible options, see [ssh\\_config manual page](#).

### Remote WAL Archive Options

This section describes the options used to provide the arguments for [remote mode options](#) in [archive-get](#) used in the [restore\\_command](#) command when restoring ARCHIVE backups or performing PITR.

`--archive-host=destination`

Provides the argument for the `--remote-host` option in the `archive-get` command.

`--archive-port=port`

Provides the argument for the `--remote-port` option in the `archive-get` command.

Default: 22

`--archive-user=username`

Provides the argument for the `--remote-user` option in the `archive-get` command. If you omit this option, the user that has started the Postgres Pro cluster is used.

Default: Postgres Pro user

### Incremental Restore Options

This section describes the options for incremental cluster restore. These options can be used with the `restore` command.

`-I incremental_mode`

`--incremental-mode=incremental_mode`

Specifies the incremental mode to be used. Possible values are:

- `CHECKSUM` — replace only pages with mismatched checksum and LSN.
- `LSN` — replace only pages with LSN greater than point of divergence.
- `NONE` — regular restore.

### Partial Restore Options

This section describes the options for partial cluster restore. These options can be used with the `restore` command.

`--db-exclude=dbname`

Specifies the name of the database to exclude from restore. All other databases in the cluster will be restored as usual, including `template0` and `template1`. This option can be specified multiple times for multiple databases.

`--db-include=dbname`

Specifies the name of the database to restore from a backup. All other databases in the cluster will not be restored, with the exception of `template0` and `template1`. This option can be specified multiple times for multiple databases.

### Replica Options

This section describes the options related to taking a backup from standby.

#### Note

Starting from `pg_probackup 2.0.24`, backups can be taken from standby without connecting to the master server, so these options are no longer required. In lower versions, `pg_probackup` had to connect to the master to determine recovery time — the earliest moment for which you can restore a consistent state of the database cluster.

`--master-db=dbname`

Deprecated. Specifies the name of the database on the master server to connect to. The connection is used only for managing the backup process, so you can connect to any existing database. Can be set in the `pg_probackup.conf` using the `set-config` command.

Default: `postgres`, the default Postgres Pro database

`--master-host=host`

Deprecated. Specifies the host name of the system on which the master server is running.

`--master-port=port`

Deprecated. Specifies the TCP port or the local Unix domain socket file extension on which the master server is listening for connections.

Default: 5432, the Postgres Pro default port

```
--master-user=username
```

Deprecated. User name to connect as.

Default: postgres, the Postgres Pro default user name

```
--replica-timeout=timeout
```

Deprecated. Wait time for WAL segment streaming via replication, in seconds. By default, `pg_probackup` waits 300 seconds. You can also define this parameter in the `pg_probackup.conf` configuration file using the [set-config](#) command.

Default: 300 sec

## How-To

All examples below assume the remote mode of operations via SSH. If you are planning to run backup and restore operation locally, skip the “Setup passwordless SSH connection” step and omit all `--remote-*` options.

Examples are based on Ubuntu 18.04, Postgres Pro 11, and `pg_probackup 2.2.0`.

- `backup` — Postgres Pro role used for connection to Postgres Pro cluster.
- `backupdb` — database used for connection to Postgres Pro cluster.
- `backup_host` — host with backup catalog.
- `backupman` — user on `backup_host` running all `pg_probackup` operations.
- `/mnt/backups` — directory on `backup_host` where backup catalog is stored.
- `postgres_host` — host with Postgres Pro cluster.
- `postgres` — user on `postgres_host` that has started the Postgres Pro cluster.
- `/var/lib/postgresql/11/main` — Postgres Pro data directory on `postgres_host`.

## Minimal Setup

This scenario illustrates setting up standalone FULL and DELTA backups.

1. **Set up passwordless SSH connection from `backup_host` to `postgres_host`:**

```
[backupman@backup_host] ssh-copy-id postgres@postgres_host
```

2. **Configure your Postgres Pro cluster.**

For security purposes, it is recommended to use a separate database for backup operations.

```
postgres=#  
CREATE DATABASE backupdb;
```

Connect to the `backupdb` database, create the `probackup` role, and grant the following permissions to this role:

```
backupdb=#  
BEGIN;  
CREATE ROLE backup WITH LOGIN REPLICATION;  
GRANT USAGE ON SCHEMA pg_catalog TO backup;  
GRANT EXECUTE ON FUNCTION pg_catalog.current_setting(text) TO backup;  
GRANT EXECUTE ON FUNCTION pg_catalog.set_config(text, text, boolean) TO backup;  
GRANT EXECUTE ON FUNCTION pg_catalog.pg_is_in_recovery() TO backup;  
GRANT EXECUTE ON FUNCTION pg_catalog.pg_start_backup(text, boolean, boolean) TO  
backup;  
GRANT EXECUTE ON FUNCTION pg_catalog.pg_stop_backup(boolean, boolean) TO backup;  
GRANT EXECUTE ON FUNCTION pg_catalog.pg_create_restore_point(text) TO backup;
```

```
GRANT EXECUTE ON FUNCTION pg_catalog.pg_switch_wal() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_last_wal_replay_lsn() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current_snapshot() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_snapshot_xmax(txid_snapshot) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_control_checkpoint() TO backup;
COMMIT;
```

**3. Initialize the backup catalog:**

```
[backupman@backup_host]$ pg_probackup-11 init -B /mnt/backups
INFO: Backup catalog '/mnt/backups' successfully initied
```

**4. Add instance pg-11 to the backup catalog:**

```
[backupman@backup_host]$ pg_probackup-11 add-instance -B /mnt/backups --
instance pg-11 --remote-host=postgres_host --remote-user=postgres -D /var/lib/
postgresql/11/main
INFO: Instance 'node' successfully initied
```

**5. Take a FULL backup:**

```
[backupman@backup_host] pg_probackup-11 backup -B /mnt/backups --instance pg-11
-b FULL --stream --remote-host=postgres_host --remote-user=postgres -U backup -d
backupdb
INFO: Backup start, pg_probackup version: 2.2.0, instance: node, backup ID: PZ7YK2,
backup mode: FULL, wal mode: STREAM, remote: true, compress-algorithm: none,
compress-level: 1
INFO: Start transferring data files
INFO: Data files are transferred
INFO: wait for pg_stop_backup()
INFO: pg_stop_backup() successfully executed
INFO: Validating backup PZ7YK2
INFO: Backup PZ7YK2 data files are valid
INFO: Backup PZ7YK2 resident size: 196MB
INFO: Backup PZ7YK2 completed
```

**6. Let's take a look at the backup catalog:**

```
[backupman@backup_host] pg_probackup-11 show -B /mnt/backups --instance pg-11

BACKUP INSTANCE 'pg-11'
=====
 Instance  Version  ID          Recovery Time          Mode  WAL Mode  TLI  Time
 Data    WAL  Zratio  Start LSN  Stop LSN   Status
=====
 node      11      PZ7YK2  2019-10-11 19:45:45+03  FULL  STREAM    1/0  11s
 180MB 16MB    1.00  0/3C000028  0/3C000198  OK
=====
```

**7. Take an incremental backup in the DELTA mode:**

```
[backupman@backup_host] pg_probackup-11 backup -B /mnt/backups --instance pg-11 -
b delta --stream --remote-host=postgres_host --remote-user=postgres -U backup -d
backupdb
INFO: Backup start, pg_probackup version: 2.2.0, instance: node, backup ID: PZ7YMP,
backup mode: DELTA, wal mode: STREAM, remote: true, compress-algorithm: none,
compress-level: 1
INFO: Parent backup: PZ7YK2
INFO: Start transferring data files
INFO: Data files are transferred
INFO: wait for pg_stop_backup()
INFO: pg_stop_backup() successfully executed
INFO: Validating backup PZ7YMP
```

```
INFO: Backup PZ7YMP data files are valid
INFO: Backup PZ7YMP resident size: 32MB
INFO: Backup PZ7YMP completed
```

8. **Let's add some parameters to pg\_probackup configuration file, so that you can omit them from the command line:**

```
[backupman@backup_host] pg_probackup-11 set-config -B /mnt/backups --instance pg-11
--remote-host=postgres_host --remote-user=postgres -U backup -d backupdb
```

9. **Take another incremental backup in the DELTA mode, omitting some of the previous parameters:**

```
[backupman@backup_host] pg_probackup-11 backup -B /mnt/backups --instance pg-11 -b
delta --stream
INFO: Backup start, pg_probackup version: 2.2.0, instance: node, backup ID: PZ7YR5,
backup mode: DELTA, wal mode: STREAM, remote: true, compress-algorithm: none,
compress-level: 1
INFO: Parent backup: PZ7YMP
INFO: Start transferring data files
INFO: Data files are transferred
INFO: wait for pg_stop_backup()
INFO: pg_stop_backup() successfully executed
INFO: Validating backup PZ7YR5
INFO: Backup PZ7YR5 data files are valid
INFO: Backup PZ7YR5 resident size: 32MB
INFO: Backup PZ7YR5 completed
```

10. **Let's take a look at the instance configuration:**

```
[backupman@backup_host] pg_probackup-11 show-config -B /mnt/backups --instance
pg-11

# Backup instance information
pgdata = /var/lib/postgresql/11/main
system-identifier = 6746586934060931492
xlog-seg-size = 16777216
# Connection parameters
pgdatabase = backupdb
pghost = postgres_host
pguser = backup
# Replica parameters
replica-timeout = 5min
# Archive parameters
archive-timeout = 5min
# Logging parameters
log-level-console = INFO
log-level-file = OFF
log-filename = pg_probackup.log
log-rotation-size = 0
log-rotation-age = 0
# Retention parameters

### Versioning

pg\_probackup follows *semantic* versioning.

### Authors

Postgres Professional, Moscow, Russia.

### Credits

pg\_probackup utility is based on pg\_arman, which was originally written by NTT and then developed and maintained by Michael Paquier.

## pg\_repack

`pg_repack` — utility and Postgres Pro Standard extension to reorganize tables

### Synopsis

```
pg_repack [option...] [dbname]
```

### Description

`pg_repack` is a Postgres Pro Standard extension which lets you remove bloat from tables and indexes, and optionally restore the physical order of clustered indexes. Unlike `CLUSTER` and `VACUUM FULL` it works online, without holding an exclusive lock on the processed tables during processing. `pg_repack` is efficient to boot, with performance comparable to using `CLUSTER` directly.

`pg_repack` is a fork of the previous [https://github.com/reorg/pg\\_reorg](https://github.com/reorg/pg_reorg) project.

You can choose one of the following methods to reorganize data:

- Online `CLUSTER` (ordered by cluster index)
- Ordering by specified columns
- Online `VACUUM FULL` (packing rows only)
- Rebuild or relocate only the indexes of a table

#### Note

Only superusers can use the utility.

#### Note

Target table must have a PRIMARY KEY, or at least a UNIQUE total index on a NOT NULL column.

### Installation

On Linux systems, `pg_repack` is provided together with Postgres Pro as a separate pre-built package and requires the `postgrespro-std-13-server` package to be installed with all the dependencies. For the list of available packages and detailed installation instructions, see [Chapter 16](#). On Windows systems, `pg_repack` is automatically installed as part of Postgres Pro.

Once you have `pg_repack` installed, load the `pg_repack` extension in the database you want to process, as follows:

```
$ psql -c "CREATE EXTENSION pg_repack" -d your_database
```

You can later remove `pg_repack` from a Postgres Pro installation using `DROP EXTENSION pg_repack`.

If you are upgrading from a previous version of `pg_repack`, just drop the old version from the database as explained above and install the new version.

### Options

#### Reorganization Options

```
-a  
--all
```

Attempt to repack all the databases of the cluster. Databases where the `pg_repack` extension is not installed will be skipped.

`-t table`  
`--table=table`

Reorganize the specified table(s) only. Multiple tables may be reorganized by writing multiple `-t` switches. By default, all eligible tables in the target databases are reorganized.

`-c schema`  
`--schema=schema`

Repack the tables in the specified schema(s) only. Multiple schemas may be repacked by writing multiple `-c` switches. Can be used in conjunction with `--tablespace` to move tables to a different tablespace.

`-o column[, ...]`  
`--order-by=column[, ...]`

Perform an online `CLUSTER` ordered by the specified columns.

`-n`  
`--no-order`

Perform an online `VACUUM FULL`. Since version 1.2 this is the default for non-clustered tables.

`-N`  
`--dry-run`

Show what would be repacked and exit.

`-j num_jobs`  
`--jobs=num_jobs`

Create the specified number of extra connections to Postgres Pro Standard, and use these extra connections to parallelize the rebuild of indexes on each table. Parallel index builds are only supported for full-table repacks, not with `--index` or `--only-indexes` options. If your server has extra cores and disk I/O available, this can be a useful way to speed up `pg_repack`.

`-s tablespace`  
`--tablespace=tablespace`

Move the repacked tables to the specified tablespace: essentially an online version of `ALTER TABLE ... SET TABLESPACE`. The tables' indexes are left in the original tablespace unless `--moveidx` is specified too.

`-S`  
`--moveidx`

Also move the indexes of the repacked tables to the tablespace specified by the `--tablespace` option.

`-i index`  
`--index=index`

Repack the specified index(es) only. Multiple indexes may be repacked by writing multiple `-i` switches. May be used in conjunction with `--tablespace` to move the index(es) to a different tablespace.

`-x`  
`--only-indexes`

Repack only the indexes of the specified table(s), which must be specified with the `--table` option.

`-T secs`  
`--wait-timeout=secs`

`pg_repack` needs to take an exclusive lock at the end of the reorganization. This setting controls how many seconds `pg_repack` will wait to acquire this lock. If the lock cannot be taken after this duration,

`pg_repack` will forcibly cancel the conflicting queries. If you are using Postgres Pro or PostgreSQL version 8.4 or newer, `pg_repack` will fall back to using `pg_terminate_backend()` to disconnect any remaining backends after this timeout has passed twice. The default is 60 seconds.

`-Z`  
`--no-analyze`

Disable `ANALYZE` after a full-table reorganization. If not specified, `ANALYZE` is executed after the reorganization.

### Connection Options

`[-d] dbname`  
`[--dbname=] dbname`

Specifies the name of the database to be reorganized. If this is not specified and `-a` (or `--all`) is not used, the database name is read from the environment variable `PGDATABASE`. If that is not set, the user name specified for the connection is used.

`-h host`  
`--host=host`

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

`-p port`  
`--port=port`

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

`-U username`  
`--username=username`

User name to connect as.

`-w`  
`--no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`  
`--password`

Force `pg_repack` to prompt for a password before connecting to a database.

This option is never essential, since `pg_repack` will automatically prompt for a password if the server demands password authentication. However, `pg_repack` will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-w` to avoid the extra connection attempt.

### Generic Options

`-e`  
`--echo`

Echo the commands that `pg_repack` generates and sends to the server.

`-E level`  
`--elevel=level`

Choose the output message level from `DEBUG`, `INFO`, `NOTICE`, `WARNING`, `ERROR`, `LOG`, `FATAL`, and `PANIC`. The default is `INFO`.

```
--help
```

Show help about `pg_repack` command line arguments, and exit.

```
-V
```

```
--version
```

Print the `pg_repack` version and exit.

## Environment

```
PGDATABASE
```

```
PGHOST
```

```
PGPORT
```

```
PGUSER
```

Default connection parameters

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by `libpq` (see [Section 31.14](#)).

## Examples

Perform an online `CLUSTER` of all the clustered tables in the database `test`, and perform an online `VACUUM FULL` of all the non-clustered tables:

```
$ pg_repack test
```

Perform an online `VACUUM FULL` on the tables `foo` and `bar` in the database `test` (an eventual cluster index is ignored):

```
$ pg_repack --no-order --table foo --table bar test
```

Move all indexes of table `foo` to tablespace `tbs`:

```
$ pg_repack -d test --table foo --only-indexes --tablespace tbs
```

Move the specified index to tablespace `tbs`:

```
$ pg_repack -d test --index idx --tablespace tbs
```

## Diagnostics

Error messages are reported when `pg_repack` fails. The following list shows the cause of errors.

You need to cleanup by hand after fatal errors. To cleanup, just remove `pg_repack` from the database and install it again.

For Postgres Pro or PostgreSQL 9.1 and newer execute:

```
DROP EXTENSION pg_repack CASCADE
```

in the database where the error occurred, followed by

```
CREATE EXTENSION pg_repack
```

For previous versions load the script `$$SHAREDIR/contrib/uninstall_pg_repack.sql` into the database where the error occurred and then load `$$SHAREDIR/contrib/pg_repack.sql` again.

```
INFO: database "db" skipped:
```

```
pg_repack VER is not installed in the database:
```

```
pg_repack is not installed in the database when the --all option is specified.
```

Create the `pg_repack` extension in the database.

```
ERROR: pg_repack VER is not installed in the database:
pg_repack is not installed in the database specified by --dbname
```

Create the `pg_repack` extension in the database.

```
ERROR: program 'pg_repack V1' does not match database library 'pg_repack V2':
There is a mismatch between the pg_repack binary and the database library
(.so or .dll).
```

The mismatch could be due to the wrong binary in the `PATH` or the wrong database being addressed. Check the program directory and the database; if they are what expected you may need to repeat `pg_repack` installation.

```
ERROR: extension 'pg_repack V1' required, found 'pg_repack V2':
The SQL extension found in the database does not match the version required by the
pg_repack program.
```

You should drop the extension from the database and reload it as described in [the section called “Installation”](#).

```
ERROR: relation "table" must have a primary key or not-null unique keys:
The target table doesn't have a PRIMARY KEY or any UNIQUE constraints defined.
```

Define a `PRIMARY KEY` or a `UNIQUE` constraint on the table.

```
ERROR: query failed: ERROR: column "col" does not exist:
The target table doesn't have columns specified by --order-by option.
```

Specify existing columns.

```
WARNING: the table "tbl" already has a trigger called z_repack_trigger:
The trigger was probably installed during a previous attempt
to run pg_repack on the table which was interrupted
and for some reason failed to clean up the temporary objects.
```

You can remove all the temporary objects by dropping and re-creating the extension: see [the section called “Installation”](#) for the details.

```
WARNING: trigger "trg" conflicting on table "tbl":
The target table has a trigger whose name follows z_repack_trigger
in alphabetical order.
```

The `z_repack_trigger` should be the last `BEFORE` trigger to fire. Please rename your trigger so that it sorts alphabetically before `pg_repack` one; you can use:

```
ALTER TRIGGER zzz_my_trigger
ON sometable RENAME TO yyy_my_trigger;
```

ERROR: Another `pg_repack` command may be running on the table. Please try again later.

There is a chance of deadlock when two concurrent `pg_repack` commands are run on the same table. So, try to run the command after some time.

WARNING: Cannot create index "schema"."index\_xxxxx", already exists  
DETAIL: An invalid index may have been left behind by a previous `pg_repack` on the table which was interrupted. Please use `DROP INDEX "schema"."index_xxxxx"` to remove this index and try again.

A temporary index apparently created by `pg_repack` has been left behind, and we do not want to risk dropping this index ourselves. If the index was in fact created by an old `pg_repack` job which didn't get cleaned up, you should just use `DROP INDEX` and try the `repack` command again.

### Restrictions

`pg_repack` comes with the following restrictions.

#### Temporary tables

`pg_repack` cannot reorganize temporary tables.

#### GiST indexes

`pg_repack` cannot cluster tables by GiST indexes.

#### DDL commands

You will not be able to perform DDL commands of the target table(s) *except* `VACUUM` or `ANALYZE` while `pg_repack` is working. `pg_repack` will hold an `ACCESS SHARE` lock on the target table during a full-table repack, to enforce this restriction.

If you are using version 1.1.8 or earlier, you must not attempt to perform any DDL commands on the target table(s) while `pg_repack` is running. In many cases `pg_repack` would fail and rollback correctly, but there were some cases in these earlier versions which could result in data corruption.

## vacuumlo

vacuumlo — remove orphaned large objects from a Postgres Pro database

### Synopsis

```
vacuumlo [option...] dbname...
```

### Description

vacuumlo is a simple utility program that will remove any “orphaned” large objects from a Postgres Pro database. An orphaned large object (LO) is considered to be any LO whose OID does not appear in any `oid` or `lo` data column of the database.

If you use this, you may also be interested in the `lo_manage` trigger in the `lo` module. `lo_manage` is useful to try to avoid creating orphaned LOs in the first place.

All databases named on the command line are processed.

### Options

vacuumlo accepts the following command-line arguments:

```
-l limit  
--limit=limit
```

Remove no more than *limit* large objects per transaction (default 1000). Since the server acquires a lock per LO removed, removing too many LOs in one transaction risks exceeding [max\\_locks\\_per\\_transaction](#). Set the limit to zero if you want all removals done in a single transaction.

```
-n  
--dry-run
```

Don't remove anything, just show what would be done.

```
-v  
--verbose
```

Write a lot of progress messages.

```
-V  
--version
```

Print the vacuumlo version and exit.

```
-?  
--help
```

Show help about vacuumlo command line arguments, and exit.

vacuumlo also accepts the following command-line arguments for connection parameters:

```
-h host  
--host=host
```

Database server's host.

```
-p port  
--port=port
```

Database server's port.

```
-U username
--username=username
```

User name to connect as.

```
-w
--no-password
```

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

```
-W
--password
```

Force vacuumlo to prompt for a password before connecting to a database.

This option is never essential, since vacuumlo will automatically prompt for a password if the server demands password authentication. However, vacuumlo will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-w` to avoid the extra connection attempt.

## Environment

```
PGHOST
PGPORT
PGUSER
```

Default connection parameters.

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by libpq (see [Section 31.14](#)).

The environment variable `PG_COLOR` specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

## Notes

vacuumlo works by the following method: First, vacuumlo builds a temporary table which contains all of the OIDs of the large objects in the selected database. It then scans through all columns in the database that are of type `oid` or `lo`, and removes matching entries from the temporary table. (Note: Only types with these names are considered; in particular, domains over them are not considered.) The remaining entries in the temporary table identify orphaned LOs. These are removed.

Peter Mount <[peter@retep.org.uk](mailto:peter@retep.org.uk)>

## G.2. Server Applications

This section covers Postgres Pro Standard server-related applications. They are typically run on the host where the database server resides. See also [Postgres Pro Server Applications](#) for information about server applications that are part of the core Postgres Pro Standard distribution.

## mamonsu

mamonsu — a monitoring agent for collecting Postgres Pro and system metrics.

### Synopsis

```
mamonsu agent [agent_action]

mamonsu bootstrap -M mamonsu_user [-c | --config] [-x | --create-extensions]
[connection_options]

mamonsu export {template | config} filename [export_options]

mamonsu report [report_options] [connection_options]

mamonsu tune [tuning_options] [connection_options]

mamonsu upload [upload_options]

mamonsu zabbix dashboard upload template_name

mamonsu zabbix {template | host | hostgroup} server_action

mamonsu zabbix item {error | lastvalue | lastclock} host_id

mamonsu zabbix version

mamonsu --version

mamonsu --help
```

### Description

mamonsu is a monitoring agent for collecting Postgres Pro and system metrics that can be visualized on the Zabbix server. Unlike the native Zabbix Agent configured to collect Postgres Pro metrics, mamonsu uses a single database connection, which allows to minimize performance impact on the monitored system.

The mamonsu agent includes the following components:

- A supervisor process that monitors database and system activity.
- Plugins that specify which Postgres Pro and system metrics to collect.
- Customizable configuration and template files that define which plugins to use and how to visualize the collected data.

mamonsu is an active agent, which means that it sends the data to the Zabbix server once it is collected. Pre-configured to monitor multiple Postgres Pro and system metrics out of the box, mamonsu can be extended with your own custom plugins to track other metrics critical for your system.

mamonsu also provides the command-line interface for updating some Zabbix server settings, as well as getting an overview of the monitored system configuration and tuning Postgres Pro and system settings on the fly. You can find the list of all mamonsu commands in [the section called “Command-Line Reference”](#).

### Installation and Setup

#### **Important**

Before you start installation, attentively read [Compatibility Considerations](#).

To use `mamonsu`, you must create a Zabbix account and set up a Zabbix server as explained in [Zabbix documentation](#). Naturally, you must also have a Postgres Pro instance up and running if you are going to monitor Postgres Pro metrics. If you are configuring your Postgres Pro cluster from scratch, see [Chapter 16](#) and [Section 17.2](#) for Postgres Pro installation and setup instructions, respectively.

### Note

While `mamonsu` can collect Postgres Pro metrics from a remote cluster, system metrics are only collected locally. If you choose to collect Postgres Pro metrics remotely, make sure to disable collection of system metrics to avoid confusion, as they will be displayed under the same host in Zabbix.

A pre-built `mamonsu` package is provided together with Postgres Pro Standard, but has a separate installer. Once you have installed `mamonsu`, complete the following steps to set up metrics collection:

#### 1. Optionally, bootstrap `mamonsu`

If you omit this step, metrics can only be collected on behalf of a superuser, which is not recommended.

In this step, the `bootstrap` command sets the `mamonsu` user, creates `mamonsu` schema in the specified or implied database, as well as extensions and objects needed for monitoring.

`bootstrap` has no mandatory options. When run without options, it takes the values needed from the configuration file (`/etc/mamonsu/agent.conf` by default). Below is a simple example of `bootstrap`:

1. In the `[postgres]` section of `agent.conf`, specify connection parameters for the Postgres Pro cluster you are going to monitor. For more details, see [Connection Parameters](#).
2. Run the following command to bootstrap `mamonsu`:

```
mamonsu bootstrap
```

This command will create the user `mamonsu` with the password `mamonsu`, create monitoring functions in the database specified in `agent.conf` and grant the right to execute them to the `mamonsu` user.

In the following example, `bootstrap` options are passed explicitly.

1. Create a non-privileged database user for `mamonsu`. For example:

```
CREATE USER mamonsu_user WITH PASSWORD 'mamonsu_password';
```

2. Create a database that will be used for connection to Postgres Pro. For example:

```
CREATE DATABASE mamonsu_database OWNER mamonsu_user;
```

3. Run the following command to bootstrap `mamonsu`:

```
mamonsu bootstrap -M mamonsu_user -x -c /etc/mamonsu/mamonsu.conf -d
mamonsu_database -U postgres --host myhost --port 5432
```

For details of the options `-M`, `-x` and `-c`, see [bootstrap](#). For details of other options, see [Connection Options](#). This command will create monitoring functions in the `mamonsu_database` and grant the right to execute them to `mamonsu_user`. The `pg_buffercache` extension will also be created to ensure collection of metrics on the shared buffer cache, and the path to the configuration file will be changed.

As a result, a superuser connection is no longer required. Note that `mamonsu` also creates several tables in the `mamonsu` schema in the specified database. Do not delete these tables as they are required for `mamonsu` to work.

#### 2. Configure `mamonsu`

Edit the `agent.conf` configuration file, which is located in the `/etc/mamonsu/` directory by default.

- Configure Zabbix-related settings. The `address` field must point to the running Zabbix server, while the `client` field must provide the name of the Zabbix host. You can find the list of hosts available for your account in the Zabbix web interface under **Configuration > Hosts**.

```
[zabbix]
; enabled by default
enabled = True
client = zabbix_host_name
address = zabbix_server
```

- By default, mamonsu will collect both Postgres Pro and system metrics. If required, you can disable metrics collection of either type by setting the `enabled` parameter to `False` in the `[postgres]` or `[system]` section of the `agent.conf` file, respectively.

```
[system]
; enabled by default
enabled = True
```

### Note

While mamonsu can collect Postgres Pro metrics from a remote cluster, system metrics are only collected locally. If you choose to collect Postgres Pro metrics remotely, make sure to disable collection of system metrics to avoid confusion, as they will be displayed under the same host in Zabbix.

- If you are going to collect Postgres Pro metrics, specify connection parameters for the Postgres Pro cluster you are going to monitor. In the `user`, `password`, and `database` fields, you must specify the `mamonsu_user`, `mamonsu_password`, and the `mamonsu_database` used for bootstrap, respectively. If you skipped the bootstrap, specify superuser credentials and the database to connect to.

```
[postgres]
; enabled by default
enabled = True
user = mamonsu_user
database = mamonsu_database
password = mamonsu_password
port = 5432
```

These are the main mamonsu settings to get started. You can also fine-tune other mamonsu settings as explained in [the section called “Configuration Parameters”](#).

### 3. Configure how to display metrics on the Zabbix server

1. Generate a template that defines how to visualize the collected metrics on the Zabbix server:

```
mamonsu export template template.xml
```

mamonsu generates the `template.xml` file in your current directory. By default, the name of the template that will be displayed in the Zabbix account is `PostgresPro-OS`, where `OS` is the name of your operating system. To get a template with a different display name, you can run the above command with the `--template-name` option.

2. Optionally, specify your Zabbix account settings in the following environment variables on your monitoring system:
  - Set the `ZABBIX_USER` and `ZABBIX_PASSWD` variables to the login and password of your Zabbix account, respectively.
  - Set the `ZABBIX_URL` to `http://zabbix/`

If you skip this step, you will have to add the following options to all `mamonsu zabbix` commands that you run:

```
--url=http://zabbix/ --user=zabbix_login --password=zabbix_password
```

3. Upload `template.xml` to the Zabbix server.

```
mamonsu zabbix template export template.xml
```

Alternatively, you can upload the template through the Zabbix web interface: log in to your Zabbix account and select **Templates > Import**.

4. Link the generated template to the host to be monitored.

In the Zabbix web interface, select your host, go to **Templates > Add**, select your template, and click **Update**.

### Tip

If you would like to link a template with a new Zabbix host, you can do it from the command line using `mamonsu zabbix` commands. See [the section called “Managing Zabbix Server Settings from the Command Line”](#) for details.

When the setup is complete, start `mamonsu`. For example, on Linux systems, you can start `mamonsu` as a service with the following command:

```
service mamonsu start
```

`mamonsu` picks up all the parameters from the `mamonsu` configuration file and starts monitoring your system.

## Command-Line Reference

### agent

Syntax:

```
mamonsu agent { metric-list | metric-get metric_name | version }
```

Provides information on the collected metrics from the command line. You can specify one of the following parameters:

```
metric-list
```

Show the list of metrics that `mamonsu` is collecting. The output of this command provides the item key of each metric, its latest value, and the time when this value was received.

```
metric-get metric_name
```

Check the latest value for the specified metric. You can get the list of available metrics using the `metric-list` option.

```
version
```

Display `mamonsu` version.

### bootstrap

Syntax:

```
mamonsu bootstrap -M mamonsu_user  
[-c[ config_file] | --config[=config_file]]  
[-x | --create-extensions] [connection_options]
```

Bootstrap mamonsu. This command can take the following options:

- M  
Specify a non-privileged user that will own all mamonsu processes.
- c *config\_file*  
--config=*config\_file*  
Specify the *agent.conf* file where the [postgres] section contains the database name to be used if --dbname is not specified through *connection\_options*.  
  
Default: /etc/mamonsu/agent.conf
- x  
--create-extensions  
Create auxiliary extensions. Only [pg\\_buffercache](#) will be currently created, which is no longer created by default.
- connection\_options*  
Provide optional *command-line connection parameters*.

## export

Syntax:

```
mamonsu export config filename.conf [--add-plugins=plugin_directory]  
mamonsu export template filename.xml [--add-plugins=plugin_directory]  
                                         [--template-name=template_name]  
                                         [--application=application_name]  
                                         [--old-zabbix]
```

Generate a template or configuration file for metrics collection. The optional parameters to customize metrics collection are as follows:

- add-plugins=*plugin\_directory*  
Collect metrics that are defined in custom plugins located in the specified *plugin\_directory*. If you are going to use custom plugins, you must provide this option when generating both the configuration file and the template.
- template-name=*template\_name*  
Specify the name of the template that will be displayed on the Zabbix server.  
  
Default: PostgresPro-OS, where OS is the name of your operating system
- application=*application\_name*  
Specify an identifier under which the collected metrics will be displayed on the Zabbix server.  
  
Default: App-PostgresPro-OS, where OS is the name of your operating system
- old-zabbix  
Export a template for Zabbix server version 4.2 or lower. By default, the template is generated in a format compatible with Zabbix 4.4 or higher.

## export zabbix-parameters

Syntax:

```
mamonsu export zabbix-parameters filename.conf [--add-plugins=plugin_directory]
```

```
[--plugin-type={pg | sys | all}]  
[--pg-version=version]  
[--config=config_file]
```

Export metrics configuration for use with the native *Zabbix agent*. The optional parameters to customize metrics collection are as follows:

```
--add-plugins=plugin_directory
```

Collect metrics that are defined in custom plugins located in the specified *plugin\_directory*. If you are going to use custom plugins, you must provide this option when generating both the configuration file and the template.

```
--plugin-type={pg | sys | all}
```

Specify the type of metrics to collect:

- `pg` for Postgres Pro metrics.
- `sys` for system metrics.
- `all` for both Postgres Pro and system metrics.

Default: `all`

```
--pg-version=version
```

Specify the major version of the server for which to configure metrics collection. *mamonsu* can collect metrics for all supported Postgres Pro versions, as well as PostgreSQL versions starting from 9.5.

Default: `10`

```
--config=config_file
```

Specify the `agent.conf` file to be used as the source for metrics definitions.

Default: `/etc/mamonsu/agent.conf`

### export zabbix-template

Syntax:

```
mamonsu export zabbix-template filename.conf [--add-plugins=plugin_directory]  
                                         [--plugin-type={pg | sys | all}]  
                                         [--template-name=template_name]  
                                         [--application=application_name]  
                                         [--config=config_file]  
                                         [--old-zabbix]
```

Export a template for use with the native *Zabbix agent*. The optional parameters to customize metrics collection are as follows:

```
--add-plugins=plugin_directory
```

Collect metrics that are defined in custom plugins located in the specified *plugin\_directory*. If you are going to use custom plugins, you must provide this option when generating both the configuration file and the template.

```
--plugin-type={pg | sys | all}
```

Specify the type of metrics to collect:

- `pg` configures Postgres Pro metrics.
- `sys` configures system metrics.
- `all` configures both Postgres Pro and system metrics.

Default: all

`--template-name=template_name`

Specify the name of the template that will be displayed on the Zabbix server.

Default: `PostgresPro-OS`, where *OS* is the name of your operating system

`--application=application_name`

Specify an identifier under which the collected metrics will be displayed on the Zabbix server.

Default: `App-PostgresPro-OS`, where *OS* is the name of your operating system

`--config=config_file`

Specify the `agent.conf` file to be used as the source for metrics definitions.

Default: `/etc/mamonsu/agent.conf`

`--old-zabbix`

Export a template for Zabbix server version 4.2 or lower. By default, the template is generated in a format compatible with Zabbix 4.4 or higher.

## report

Syntax:

```
mamonsu report [--run-system=Boolean] [--run-postgres=Boolean]  
               [--print-report=Boolean] [--report-path=report_file]  
               [--disable-sudo] [connection_options]
```

Generate a detailed report on the hardware, operating system, memory usage and other parameters of the monitored system, as well as Postgres Pro configuration.

The following optional parameters customize the report:

`--run-system=Boolean`

Include system information into the generated report.

Default: `True`

`--run-postgres=Boolean`

Include information on Postgres Pro into the generated report.

Default: `True`

`--print-report=Boolean`

Print the report to stdout.

Default: `True`

`--report-path=report_file`

Save the report into the specified file.

Default: `/tmp/report.txt`

`--disable-sudo`

Do not report data that can only be received with superuser rights. This option is only available for Linux systems.

*connection\_options*

Provide optional *command-line connection parameters*.

## tune

Syntax:

```
mamonsu tune [--dry-run] [--disable-sudo] [--log-level {INFO|DEBUG|WARN}]
             [--dont-tune-pgbadger] [--dont-reload-postgresql]
             [connection_options]
```

Optimize Postgres Pro and system configuration based on the collected statistics. You can use the following options:

`--dry-run`

Display the settings to be tuned without changing the actual system and Postgres Pro configuration.

`--disable-sudo`

Do not tune the settings that can only be changed by a superuser. This option is only available for Linux systems.

`--dont-tune-pgbadger`

Do not tune pgbadger parameters.

`--log-level { INFO | DEBUG | WARN }`

Change the logging level.

Default: INFO

`--dont-reload-postgresql`

Forbid mamonsu to run the `pg_reload_conf()` function. If you specify this option, the modified settings that require reloading Postgres Pro configuration do not take effect immediately.

*connection\_options*

Provide optional *command-line connection parameters*.

## upload

Syntax:

```
mamonsu upload [--zabbix-file=metrics_file]
               [--zabbix-address=zabbix_address] [--zabbix-port=port_number]
               [--zabbix-client=zabbix_host_name] [--zabbix-log-level={INFO|DEBUG|
WARN}]
```

Upload metrics data previously saved into a file onto a Zabbix server for visualization. For details on how to save metrics into a file, see [the section called “Logging Parameters”](#).

This command can take the following options:

`--zabbix-address=zabbix_address`

The address of the Zabbix server.

Default: localhost

`--zabbix-port=port_number`

The port of the Zabbix server.

Default: 10051

`--zabbix-file=metrics_file`

A text file that stores the collected metrics data to be visualized, such as `localhost.log`.

`--zabbix-client=zabbix_host_name`

The name of the Zabbix host.

Default: `localhost`

`--zabbix-log-level={INFO|DEBUG|WARN}`

Change the logging level.

Default: `INFO`

### **zabbix dashboard upload**

Syntax:

```
mamonsu dashboard upload template_name
```

Upload a Zabbix dashboard with the mamonsu metrics to a template on the Zabbix server version 6.0 or higher.

### **zabbix item**

Syntax:

```
mamonsu zabbix item {error | lastvalue | lastclock } host_name
```

View the specified property of the latest metrics data received by Zabbix for the specified host.

### **zabbix version**

Syntax:

```
mamonsu zabbix version
```

Get the version of the Zabbix server that mamonsu is connected to.

### **zabbix host**

Syntax:

```
mamonsu zabbix host list
mamonsu zabbix host show host_name
mamonsu zabbix host id host_name
mamonsu zabbix host delete host_id
mamonsu zabbix host create host_name hostgroup_id template_id mamonsu_address
mamonsu zabbix host info {templates | hostgroups | graphs | items} host_id
```

Manage Zabbix hosts using one of the actions described in [the section called “Zabbix Server Actions”](#).

### **zabbix hostgroup**

Syntax:

```
mamonsu zabbix hostgroup list
mamonsu zabbix hostgroup show hostgroup_name
mamonsu zabbix hostgroup id hostgroup_name
mamonsu zabbix hostgroup delete hostgroup_id
mamonsu zabbix hostgroup create hostgroup_name
```

Manage Zabbix host groups using one of the actions described in [the section called “Zabbix Server Actions”](#).

## **zabbix template**

Syntax:

```
mamonsu zabbix template list
mamonsu zabbix template show template_name
mamonsu zabbix template id template_name
mamonsu zabbix template delete template_id
mamonsu zabbix template export file
```

Manage Zabbix templates using one of the actions described in [the section called “Zabbix Server Actions”](#).

## **--version**

Syntax:

```
mamonsu --version
```

Display mamonsu version.

## **--help**

Syntax:

```
mamonsu --help
```

Display mamonsu command-line help.

## **Connection Options**

*connection\_options* provide command-line connection parameters for the target Postgres Pro cluster. *connection\_options* can be `--host`, `--port`, `--dbname (-d)`, `--username (-U)`, and `--password (-W)`. The `--dbname` option should specify the *mamonsu\_database* created for monitoring purposes. Note that the `--username (-U)` option must specify a superuser that can access the cluster.

If you omit *connection\_options*, mamonsu checks the configuration file for the needed settings.

## **Zabbix Server Actions**

Using mamonsu, you can control some of the Zabbix server functionality from the command line. Specifically, you can create or delete Zabbix hosts and host groups, as well as generate, import, and delete Zabbix templates using one of the following commands. The *object\_name* to use must correspond to the type of the Zabbix object specified in the command: *template*, *host*, or *hostgroup*.

```
list
```

Display the list of available templates, hosts, or host groups.

```
show object_name
```

Display the details about the specified template, host, or host group.

```
id object_name
```

Show the ID of the specified object, which is assigned automatically by the Zabbix server.

```
delete object_id
```

Delete the object with the specified ID.

```
create hostgroup_name
```

```
create host_name hostgroup_id template_id mamonsu_address
```

Create a new host or a host group.

`export template_name`

Generate a Zabbix template.

`info {templates | hostgroups | graphs | items} host_id`

Display detailed information about the templates, host groups, graphs, and metrics available on the host with the specified ID.

### Configuration Parameters

The `agent.conf` configuration file is located in the `/etc/mamonsu` directory by default. It provides several groups of parameters that control which metrics to collect and how to log the collected data:

- [connection parameters](#)
- [logging parameters](#)
- [plugin parameters](#)

All parameters must be specified in the `parameter = value` format.

### Connection Parameters

#### [postgres]

The `[postgres]` section controls Postgres Pro metrics collection and can contain the following parameters:

`enabled`

Enables/disables Postgres Pro metrics collection if set to `True` or `False`, respectively.

Default: `True`

`user`

The user on behalf of which the cluster will be monitored. It must be the `mamonsu` user set in `bootstrap`, or a superuser if `bootstrap` was not run.

Default: `postgres`

`password`

The password for the specified user.

`database`

The database to connect to for metrics collection.

Default: `postgres`

`host`

The server address to connect to.

Default: `localhost`

`port`

The port to connect to.

Default: `5432`

`application_name`

Application name that identifies `mamonsu` connected to the Postgres Pro cluster.

Default: mamonsu

query\_timeout

[statement\\_timeout](#) for the mamonsu session, in seconds. If a Postgres Pro metric query does not complete within this time interval, it gets terminated.

Default: 10

#### **[system]**

The `[system]` section controls system metrics collection and can contain the following parameters:

enabled

Enables/disables system metrics collection if set to `True` or `False`, respectively.

Default: `True`

#### **[zabbix]**

The `[zabbix]` section provides connection settings for the Zabbix server and can contain the following parameters:

enabled

Enables/disables sending the collected metrics data to the Zabbix server if set to `True` or `False`, respectively.

Default: `True`

client

The name of the Zabbix host.

address

The address of the Zabbix server.

Default: `127.0.0.1`

port

The port of the Zabbix server.

Default: `10051`

timeout

Maximum time to wait while connecting to the Zabbix server, in seconds.

Default: `15`

#### **[agent]**

The `[agent]` section specifies the location of mamonsu and whether it is allowed to access metrics from the command line:

enabled

Enables/disables metrics collection from the command line using the `agent` command.

Default: `True`

host

The address of the system on which mamonsu is running.

Default: 127.0.0.1

port

The port on which mamonsu is running.

Default: 10052

#### **[sender]**

The [sender] section controls the queue size of the data to be sent to the Zabbix server:

queue

The maximum number of collected metric values that can be accumulated locally before mamonsu sends them to the Zabbix server. Once the accumulated data is sent, the queue is cleared.

Default: 2048

### **Logging Parameters**

#### **[metric\_log]**

The [metric\_log] section enables storing the collected metrics data in text files locally. This section can contain the following parameters:

enabled

Enables/disables storing the collected metrics data in a text file. If this option is set to `True`, mamonsu creates the `localhost.log` file for storing metric values.

Default: `False`

directory

Specifies the directory where log files with metrics data will be stored.

Default: `/var/log/mamonsu`

max\_size\_mb

The maximum size of a log file, in MB. When the specified size is reached, it is renamed to `localhost.log.archive`, and an empty `localhost.log` file is created.

Default: 1024

#### **[log]**

The [log] section specifies logging settings for mamonsu and can contain the following parameters:

file

Specifies the log filename, which can be preceded by the full path.

level

Specifies the debug level. This option can take `DEBUG`, `ERROR`, or `INFO` values.

Default: `INFO`

format

The format of the logged data.

Default: `[% (levelname)s] %(asctime)s - %(name)s - %(message)s`

where `levelname` is the debug level, `asctime` returns the current time, `name` specifies the plugin that emitted this log entry or `root` otherwise, and `message` provides the actual log message.

## Plugin Parameters

### [plugins]

The [plugins] section specifies custom plugins to be added for metrics collection and can contain the following parameters:

enabled

Enables/disables using custom plugins for metrics collection if set to `True` or `False`, respectively.

Default: `False`

directory

Specifies the directory that contains custom plugins for metrics collection. Setting this parameter to `None` forbids using custom plugins.

Default: `/etc/mamonsu/plugins`

If you need to configure any of the plugins you add to mamonsu after installation, you have to add this plugin section to the `agent.conf` file.

The syntax of this section should follow the syntax used with the examples shown below in [the section called "Individual Plugin Sections"](#).

### Individual Plugin Sections

All built-in plugins are installed along with mamonsu. To configure a built-in plugin you should find a corresponding section below the `Individual Plugin Sections` heading and edit its parameter values.

To disable any plugin you should set the `enabled` parameter to `False` and to enable it — set it to `True`. These values are case sensitive.

The example below shows individual plugin sections corresponding to the `preparedtransaction` and the `pgprobackup` built-in plugins:

```
[preparedtransaction]
max_prepared_transaction_time = 60
interval = 60

[pgprobackup]
enabled = false
interval = 300
backup_dirs = /backup_dir1,/backup_dir2
pg_probackup_path = /usr/bin/pg_probackup-11
```

### [preparedtransaction]

This plugin gets age in seconds of the oldest prepared transaction and number of all transactions prepared for a two-phase commit. For additional information refer to [PREPARE TRANSACTION and Section 49.77](#).

The `max_prepared_transaction_time` parameter specifies the threshold in seconds for the age of the prepared transaction.

The `interval` parameter allows you to change the metrics collection interval.

The plugin collects two metrics: `pgsql.prepared.count` (number of prepared transactions) and `pgsql.prepared.oldest` (oldest prepared transaction age in seconds).

If `pgsql.prepared.oldest` value exceeds the threshold specified by the `max_prepared_transaction_time` parameter, a trigger with the following message is fired: "PostgreSQL prepared transaction is too old on {host}".

**[pgprobackup]**

This plugin uses `pg_probackup` to track its backups' state and gets size of backup directories which store all backup files.

Please note that this plugin counts the total size of all files in the target directory. Make sure that extraneous files are not stored in this directory.

The `backup_dirs` parameter specifies a comma-separated list of paths to directories for which metrics should be collected.

The `pg_probackup_path` parameter specifies the path to `pg_probackup`.

The `interval` parameter allows you to change the metrics collection interval.

By default this plugin is disabled. To enable it set the `enabled` parameter to `True`.

This plugin collects two metrics: `pg_probackup.dir.size[#backup_directory]` (the size of the target directory) and `pg_probackup.dir.error[#backup_directory]` (backup errors) for each specified `backup_directory`.

If any generated backup has bad status, like `ERROR`, `CORRUPT`, `ORPHAN`, a trigger is fired.

## Usage

### Collecting and Viewing Metrics Data

Once started, `mamonsu` begins collecting system and Postgres Pro metrics. The `agent` command enables you to get an overview of the collected metrics from the command line in real time.

To view the list of available metrics, use the `agent metric-list` command:

```
mamonsu agent metric-list
```

The output of this command provides the item key of each metric, its latest value, and the time when this value was received. For example:

```
system.memory[active]          7921004544    1564570818
system.memory[swap_cache]      868352       1564570818
pgsql.connections[idle]        6.0          1564570818
pgsql.archive_command[failed_trying_to_archive] 0           1564570818
```

To view the current value for a specific metric, you can use the `agent metric-get` command:

```
mamonsu agent metric-get metric_name
```

where `metric_name` is the item key of the metric to monitor, as returned by the `metric-list` command. For example, `pgsql.connections[idle]`.

You can view graphs for the collected metrics in the Zabbix web interface under the **Graphs** menu. For details on working with Zabbix, see its official documentation at <https://www.zabbix.com/documentation/current/>.

If you have chosen to save all the collected metrics data into a file, as explained in [the section called "Logging Parameters"](#), you can later upload these metrics onto a Zabbix server for visualization using the `upload` command.

### Adding Custom Plugins

You can extend `mamonsu` with your own custom plugins, as follows:

1. Save all custom plugins in a single directory, such as `/etc/mamonsu/plugins`.
2. Make sure this directory is specified in your configuration file under the `[plugins]` section:

```
[plugins]
directory = /etc/mamonsu/plugins
```

3. Generate a new Zabbix template to include custom plugins:

```
mamonsu export template template.xml --add-plugins=/etc/mamonsu/plugins
```

4. Upload the generated `template.xml` to the Zabbix server as explained in [the section called “Installation and Setup”](#).

### Tuning Postgres Pro and System Configuration

Based on the collected metrics data, mamonsu can tune your Postgres Pro and system configuration for optimal performance.

You can get detailed information about the hardware, operating system, memory usage and other parameters of the monitored system, as well as Postgres Pro configuration, as follows:

```
mamonsu report
```

To view the suggested optimizations without applying them, run the `tune` command with the `--dry-run` option:

```
mamonsu tune --dry-run
```

To apply all the suggested changes, run the `tune` command without any parameters:

```
mamonsu tune
```

You can exclude some settings from the report or disable some of the optimizations by passing optional parameters. See [the section called “Command-Line Reference”](#) for the full list of parameters available for `report` and `tune` commands.

### Managing Zabbix Server Settings from the Command Line

mamonsu enables you to work with the Zabbix server from the command line. You can upload template files to Zabbix, create and delete Zabbix hosts and host groups, link templates with hosts and check the latest metric values.

To set up your Zabbix host from scratch, you can follow these steps:

1. Optionally, specify your Zabbix account settings in the following environment variables on your monitoring system:
  - Set the `ZABBIX_USER` and `ZABBIX_PASSWD` variables to the login and password of your Zabbix account, respectively.
  - Set the `ZABBIX_URL` to `http://zabbix/`

If you skip this step, you will have to add the following options to all `mamonsu zabbix` commands that you run:

```
--url=http://zabbix/ --user=zabbix_login --password=zabbix_password
```

2. Generate a new template file and upload it to the Zabbix server:

```
mamonsu export template template.xml
mamonsu zabbix template export template.xml
```

3. Create a new host group:

```
mamonsu zabbix hostgroup create hostgroup_name
```

4. Check the IDs for this host group and the uploaded template, which are assigned automatically by the Zabbix server:

```
mamonsu zabbix hostgroup id hostgroup_name
```

```
mamonsu zabbix template id template_name
```

5. Create a host associated with this group and link it with the uploaded template using a single command:

```
mamonsu zabbix host create host_name hostgroup_id template_id mamonsu_address
```

where *host\_name* is the name of the host, *hostgroup\_id* and *template\_id* are the unique IDs returned in the previous step, and *mamonsu\_address* is the IP address of the system on which mamonsu runs.

Once your Zabbix host is configured, complete the setup of your monitoring system as explained in [the section called “Installation and Setup”](#).

### Exporting Metrics for Native Zabbix Agent

Using mamonsu, you can convert system and Postgres Pro metrics definitions to the format supported by the native [Zabbix agent](#).

This feature currently has the following limitations:

- You cannot export metrics if you run `mamonsu` on Windows systems.
- Metrics definitions for `pg_wait_sampling` and CFS features available in Postgres Pro Enterprise are not converted.

To collect metrics provided by mamonsu using the native Zabbix agent, do the following:

1. Generate a configuration file that is compatible with the native Zabbix agent and place it under `/etc/zabbix/zabbix_agent.d/`. You can prepend the filename with the required path:

```
mamonsu export zabbix-parameters /etc/zabbix/zabbix_agent.d/zabbix_agent.conf
```

For all possible options of the `export zabbix-parameters` command, see [the section called “Command-Line Reference”](#).

2. Generate a template for the native Zabbix agent:

```
mamonsu export zabbix-template template.xml
```

For all possible options of the `export zabbix-template` command, see [the section called “Command-Line Reference”](#).

3. Upload the generated template to the Zabbix server, as explained in [the section called “Installation and Setup”](#).
4. If you are going to collect Postgres Pro metrics, change the following macros in the template after the upload:
  - For `{$PG_CONNINFO}`, provide connection parameters for the Postgres Pro server to be monitored.
  - For `{$PG_PATH}`, specify `psql` installation directory.

### Compatibility Considerations

If you want to upgrade mamonsu to a version that is not compatible with the previous one, what you must do to continue using the application depends on whether you need to retain the metrics data collected.

- If you need to retain the collected data, do the following:
  1. Install the new version of mamonsu.
  2. Generate a new template for the Zabbix server.
  3. If you performed a bootstrap using the previous version of mamonsu, run the `bootstrap` command again.
  4. Upload the new template to the Zabbix server.

5. Rename the host for which you want to retain the collected data and leave the old template linked to that host.
  6. Create a new host for the same system and link the new template to it.
  7. Restart mamonsu. It will collect data for the new host. The old host will no longer be used, but the data collected will be available.
- If you do not need to retain the collected data, do the following:
    1. Install the new version of mamonsu.
    2. Generate a new template for the Zabbix server.
    3. If you performed a bootstrap using the previous version of mamonsu, run the `bootstrap` command again.
    4. Upload the new template to the Zabbix server.
    5. In the settings of the Zabbix host, link the new template to the host instead of the old one.
    6. Restart mamonsu. It will start collecting data. All the data collected earlier will be lost.

## pgbouncer

pgbouncer — a Postgres Pro connection pooler

### Synopsis

On Linux systems:

```
pgbouncer [ -d ] [ -R ] [ -v ] [ -u user ] pgbouncer.ini
```

```
pgbouncer -V | -h
```

On Windows:

```
pgbouncer [ -v ] [ -u user ] pgbouncer.ini
```

```
pgbouncer -V | -h
```

To use pgbouncer as a Windows service:

```
pgbouncer.exe --regservice pgbouncer.ini
```

```
pgbouncer.exe --unregservice pgbouncer.ini
```

### Description

pgbouncer is a Postgres Pro connection pooler. Any target application can be connected to pgbouncer as if it were a Postgres Pro server, and pgbouncer will create a connection to the actual server, or it will reuse one of its existing connections.

The aim of pgbouncer is to lower the performance impact of opening new connections to Postgres Pro.

In order not to compromise transaction semantics for connection pooling, pgbouncer supports several types of pooling when rotating connections:

#### Session pooling

Most polite method. When a client connects, a server connection will be assigned to it for the whole duration the client stays connected. When the client disconnects, the server connection will be put back into the pool. This is the default method.

#### Transaction pooling

A server connection is assigned to a client only during a transaction. When pgbouncer notices that transaction is over, the server connection will be put back into the pool.

#### Statement pooling

Most aggressive method. The server connection will be put back into the pool immediately after a query completes. Multi-statement transactions are disallowed in this mode as they would break.

The administration interface of pgbouncer consists of some new `SHOW` commands available when connected to a special “virtual” database `pgbouncer`.

### Quick Start

Basic setup and usage is as follows.

1. Create a `pgbouncer.ini` file. Details in the `pgbouncer(5)` man page. Simple example:

```
[databases]
template1 = host=localhost dbname=template1 auth_user=someuser
```

```
[pgbouncer]
listen_port = 6432
listen_addr = localhost
auth_type = md5
auth_file = userlist.txt
logfile = pgbouncer.log
pidfile = pgbouncer.pid
admin_users = someuser
```

2. Create a `userlist.txt` file that contains the users allowed in:

```
"someuser" "same_password_as_in_server"
```

3. Launch `pgbouncer`:

```
$ pgbouncer -d pgbouncer.ini
```

### Note

The above command does not work on Windows systems. Instead, `pgbouncer` must be launched as a service that first needs to be registered, as follows:

```
pgbouncer --regservice
```

4. Have your application (or the `psql` client) connect to `pgbouncer` instead of directly to the PostgreSQL server:

```
$ psql -p 6432 -U someuser template1
```

5. Manage `pgbouncer` by connecting to the special administration database `pgbouncer` and issuing `SHOW HELP`; to begin:

```
$ psql -p 6432 -U someuser pgbouncer
pgbouncer=# SHOW HELP;
NOTICE:  Console usage
DETAIL:
SHOW [HELP|CONFIG|DATABASES|FDS|POOLS|CLIENTS|SERVERS|SOCKETS|LISTS|VERSION|...]
SET key = arg
RELOAD
PAUSE
SUSPEND
RESUME
SHUTDOWN
[...]
```

6. If you made changes to the `pgbouncer.ini` file, you can reload it with:

```
pgbouncer=# RELOAD;
```

## Options

`-d, --daemon`

Run in the background. Without it, the process will run in the foreground. In daemon mode, setting `pidfile` as well as `logfile` or `syslog` is required. No log messages will be written to `stderr` after going into the background.

### Note

Does not work on Windows, `pgbouncer` needs to run as service there.

`-R, --reboot`

Do an online restart. That means connecting to the running process, loading the open sockets from it, and then using them. If there is no active process, boot normally.

### Note

Works only if OS supports Unix sockets and the `unix_socket_dir` is not disabled in configuration. Does not work on Windows. Does not work with TLS connections, they are dropped.

`-u user, --user user`

Switch to the given user on startup.

`-v, --verbose`

Increase verbosity. Can be used multiple times.

`-q, --quiet`

Be quiet: do not log to stderr. This does not affect logging verbosity, only that stderr is not to be used. For use in `init.d` scripts.

`-V, --version`

Show version.

`-h, --help`

Show short help.

`--regservice`

Win32: Register to run as Windows service. The `service_name` configuration parameter value is used as the name to register under.

`--unregservice`

Win32: Unregister Windows service.

## Admin Console

The console is available by connecting as normal to the database `pgbouncer`:

```
$ psql -p 6432 pgbouncer
```

Only users listed in the configuration parameters `admin_users` or `stats_users` are allowed to log in to the console. (Except when `auth_mode=any`, then any user is allowed in as a `stats_user`.)

Additionally, the user name `pgbouncer` is allowed to log in without password, if the login comes via the Unix socket and the client has same Unix user uid as the running process.

## Show Commands

The `SHOW` commands output information. Each command is described below.

### SHOW STATS

Shows statistics. In this and related commands, the total figures are since process start, the averages are updated every `stats_period`.

database

Statistics are presented per database.

`total_xact_count`

Total number of SQL transactions pooled by pgbouncer.

`total_query_count`

Total number of SQL queries pooled by pgbouncer.

`total_received`

Total volume in bytes of network traffic received by pgbouncer.

`total_sent`

Total volume in bytes of network traffic sent by pgbouncer.

`total_xact_time`

Total number of microseconds spent by pgbouncer when connected to Postgres Pro in a transaction, either idle in transaction or executing queries.

`total_query_time`

Total number of microseconds spent by pgbouncer when actively connected to Postgres Pro, executing queries.

`total_wait_time`

Time spent by clients waiting for a server, in microseconds.

`avg_xact_count`

Average transactions per second in last stat period.

`avg_query_count`

Average queries per second in last stat period.

`avg_recv`

Average received (from clients) bytes per second.

`avg_sent`

Average sent (to clients) bytes per second.

`avg_xact_time`

Average transaction duration, in microseconds.

`avg_query_time`

Average query duration, in microseconds.

`avg_wait_time`

Time spent by clients waiting for a server, in microseconds (average per second).

**SHOW STATS\_TOTALS**

Subset of `SHOW STATS` showing the total values (`total_`).

**SHOW STATS\_AVERAGES**

Subset of `SHOW STATS` showing the average values (`avg_`).

**SHOW TOTALS**

Like `SHOW STATS` but aggregated across all databases.

**SHOW SERVERS**

type

S, for server.

user

User name pgbouncer uses to connect to server.

database

Database name.

state

State of the pgbouncer server connection, one of active, idle, used, tested, or new.

addr

IP address of Postgres Pro server.

port

Port of Postgres Pro server.

local\_addr

Connection start address on local machine.

local\_port

Connection start port on local machine.

connect\_time

When the connection was made.

request\_time

When last request was issued.

wait

Current waiting time in seconds.

wait\_us

Microsecond part of the current waiting time.

close\_needed

1 if the connection will be closed as soon as possible, because a configuration file reload or DNS update changed the connection information or RECONNECT was issued.

ptr

Address of internal object for this connection. Used as unique ID.

link

Address of client connection the server is paired with.

remote\_pid

PID of backend server process. In case connection is made over Unix socket and OS supports getting process ID info, its OS PID. Otherwise it's extracted from cancel packet the server sent, which should

be the PID in case the server is Postgres Pro, but it's a random number in case the server is another pgbouncer.

tls

A string with TLS connection information, or empty if not using TLS.

#### **SHOW CLIENTS**

type

C, for client.

user

Client connected user.

database

Database name.

state

State of the client connection, one of `active` or `waiting`.

addr

IP address of the client.

port

Source port of the client.

local\_addr

Connection end address on local machine.

local\_port

Connection end port on local machine.

connect\_time

Timestamp of connect time.

request\_time

Timestamp of latest client request.

wait

Current waiting time in seconds.

wait\_us

Microsecond part of the current waiting time.

close\_needed

Not used for clients.

ptr

Address of internal object for this connection. Used as unique ID.

link

Address of server connection the client is paired with.

`remote_pid`

Process ID, in case client connects over Unix socket and OS supports getting it.

`tls`

A string with TLS connection information, or empty if not using TLS.

#### **SHOW POOLS**

A new pool entry is made for each couple of (database, user).

`database`

Database name.

`user`

User name.

`cl_active`

Client connections that are linked to server connection and can process queries.

`cl_waiting`

Client connections that have sent queries but have not yet got a server connection.

`cl_cancel_req`

Client connections that have not forwarded query cancellations to the server yet.

`sv_active`

Server connections that are linked to a client.

`sv_idle`

Server connections that are unused and immediately usable for client queries.

`sv_used`

Server connections that have been idle for more than `server_check_delay`, so they need `server_check_query` to run on them before they can be used again.

`sv_tested`

Server connections that are currently running either `server_reset_query` or `server_check_query`.

`sv_login`

Server connections currently in the process of logging in.

`maxwait`

How long the first (oldest) client in the queue has waited, in seconds. If this starts increasing, then the current pool of servers does not handle requests quickly enough. The reason may be either an overloaded server or just too small of a `pool_size` setting.

`maxwait_us`

Microsecond part of the maximum waiting time.

`pool_mode`

The pooling mode in use.

#### **SHOW LISTS**

Show following internal information, in columns (not rows):

databases

Count of databases.

users

Count of users.

pools

Count of pools.

free\_clients

Count of free clients.

used\_clients

Count of used clients.

login\_clients

Count of clients in login state.

free\_servers

Count of free servers.

used\_servers

Count of used servers.

dns\_names

Count of DNS names in the cache.

dns\_zones

Count of DNS zones in the cache.

dns\_queries

Count of in-flight DNS queries.

dns\_pending

Not used.

#### **SHOW USERS**

name

The user name.

pool\_mode

The user's override `pool_mode`, or `NULL` if the default will be used instead.

#### **SHOW DATABASES**

name

Name of configured database entry.

host

Host pgbouncer connects to.

port

Port pgbouncer connects to.

database

Actual database name pgbouncer connects to.

force\_user

When the user is part of the connection string, the connection between pgbouncer and Postgres Pro is forced to the given user, whatever the client user.

pool\_size

Maximum number of server connections.

min\_pool\_size

Minimum number of server connections.

reserve\_pool

Maximum number of additional connections for this database.

pool\_mode

The database's override pool\_mode, or NULL if the default will be used instead.

max\_connections

Maximum number of allowed connections for this database, as set by max\_db\_connections, either globally or per database.

current\_connections

Current number of connections for this database.

paused

1 if this database is currently paused, else 0.

disabled

1 if this database is currently disabled, else 0.

#### SHOW FDS

Internal command — shows list of file descriptors (FDs) in use with internal state attached to them.

When the connected user has the user name pgbouncer, connects through the Unix socket and has the same UID as the running process, the actual FDs are passed over the connection. This mechanism is used to do an online restart.

<p style="text-align: center;"><b>Note</b></p>
--

<p>This does not work on Windows.</p>
---------------------------------------

This command also blocks the internal event loop, so it should not be used while pgbouncer is in use.

fd

File descriptor numeric value.

task

One of pooler, client or server.

user

User of the connection using the FD.

database

Database of the connection using the FD.

addr

IP address of the connection using the FD, `unix` if a Unix socket is used.

port

Port used by the connection using the FD.

cancel

Cancel key for this connection.

link

File descriptor for corresponding server/client. `NULL` if idle.

#### **SHOW SOCKETS, SHOW ACTIVE\_SOCKETS**

Shows low-level information about sockets or only active sockets. This includes the information shown under `SHOW CLIENTS` and `SHOW SERVERS` as well as other more low-level information.

#### **SHOW CONFIG**

Show the current configuration settings, one per row, with the following columns:

key

Configuration variable name.

value

Configuration value.

default

Configuration default value.

changeable

Either `yes` or `no`, shows if the variable can be changed while running. If `no`, the variable can be changed only at boot-time. Use `SET` to change a variable at run time.

#### **SHOW MEM**

Shows low-level information about the current sizes of various internal memory allocations. The information presented is subject to change.

#### **SHOW DNS\_HOSTS**

Show host names in DNS cache.

hostname

Host name.

ttd

How many seconds until next lookup.

addrs

Comma separated list of addresses.

#### **SHOW DNS\_ZONES**

Show DNS zones in cache.

zonename

Zone name.

serial

Current serial.

count

Host names belonging to this zone.

#### **SHOW VERSION**

Show the pgbouncer version string.

#### **Process Controlling Commands**

##### **PAUSE** [*db*]

pgbouncer tries to disconnect from all servers, first waiting for all queries to complete. The command will not return before all queries are finished. To be used at the time of database restart.

If database name is given, only that database will be paused.

New client connections to a paused database will wait until `RESUME` is called.

##### **DISABLE** *db*

Reject all new client connections on the given database.

##### **ENABLE** *db*

Allow new client connections after a previous `DISABLE` command.

##### **RECONNECT** *db*

Close each open server connection for the given database, or all databases, after it is released (according to the pooling mode), even if its lifetime is not up yet. New server connections can be made immediately and will connect as necessary according to the pool size settings.

This command is useful when the server connection setup has changed, for example to perform a gradual switchover to a new server. It is not necessary to run this command when the connection string in `pgbouncer.ini` has been changed and reloaded (see `RELOAD`) or when DNS resolution has changed, because then the equivalent of this command will be run automatically. This command is only necessary if something downstream of pgbouncer routes the connections.

After this command is run, there could be an extended period where some server connections go to an old destination and some server connections go to a new destination. This is likely only sensible when switching read-only traffic between read-only replicas, or when switching between nodes of a multimaster replication setup. If all connections need to be switched at the same time, `PAUSE` is recommended instead. To close server connections without waiting (for example, in emergency failover rather than gradual switchover scenarios), also consider `KILL`.

##### **KILL** *db*

Immediately drop all client and server connections on given database.

New client connections to a killed database will wait until `RESUME` is called.

##### **SUSPEND**

All socket buffers are flushed and pgbouncer stops listening for data on them. The command will not return before all buffers are empty. To be used at the time of pgbouncer online reboot.

New client connections to a suspended database will wait until `RESUME` is called.

### **RESUME [*db*]**

Resume work from previous `KILL`, `PAUSE`, or `SUSPEND` command.

### **SHUTDOWN**

The `pgbouncer` process will exit.

### **RELOAD**

The `pgbouncer` process will reload its configuration file and update changeable settings.

PgBouncer notices when a configuration file reload changes the connection parameters of a database definition. An existing server connection to the old destination will be closed when the server connection is next released (according to the pooling mode), and new server connections will immediately use the updated connection parameters.

### **WAIT\_CLOSE [*db*]**

Wait until all server connections, either of the specified database or of all databases, have cleared the `close_needed` state (see [the section called “SHOW SERVERS”](#)). This can be called after a `RECONNECT` or `RELOAD` to wait until the respective configuration change has been fully activated, for example in switchover scripts.

### **Other Commands**

#### **SET *key* = *arg***

Changes a configuration setting (see also [the section called “SHOW CONFIG”](#)). For example:

```
SET log_connections = 1;
SET server_check_query = 'select 2';
```

(Note that this command is run on the `pgbouncer` admin console and sets `pgbouncer` settings. A `SET` command run on another database will be passed to the Postgres Pro backend like any other SQL command.)

### **Signals**

`SIGHUP`

Reload config. Same as issuing the command `RELOAD` on the console.

`SIGINT`

Safe shutdown. Same as issuing `PAUSE` and `SHUTDOWN` on the console.

`SIGTERM`

Immediate shutdown. Same as issuing `SHUTDOWN` on the console.

`SIGUSR1`

Same as issuing `PAUSE` on the console.

`SIGUSR2`

Same as issuing `RESUME` on the console.

### **Libevent Settings**

From the libevent documentation:

It is possible to disable support for `epoll`, `kqueue`, `devpoll`, `poll`, or `select` by setting the environment variable `EVENT_NOEPOLL`, `EVENT_NOKQUEUE`, `EVENT_NODEVPOLL`, `EVENT_NOPOLL` or `EVENT_NOSELECT`, respectively.

By setting the environment variable `EVENT_SHOW_METHOD`, `libevent` displays the kernel notification method that it uses.

### `pgbouncer.ini` Configuration File

The configuration file is in the `.ini` format. Section names are between `[` and `]`. Lines starting with `;` or `#` are taken as comments and ignored. The characters `;` and `#` are not recognized as special when they appear later in the line.

#### Generic Settings

##### `logfile`

Specifies the log file. For daemonization (`-d`), either this or `syslog` has to be set. The log file is kept open, so after rotation `kill -HUP` or on console `RELOAD`; should be done. On Windows, the service must be stopped and started.

Note that setting `logfile` does not by itself turn off logging to `stderr`. Use the command-line option `-q` or `-d` for that.

Default: not set

##### `pidfile`

Specifies the PID file. Without `pidfile` set, daemonization (`-d`) is not allowed.

Default: not set

##### `listen_addr`

Specifies a list of addresses where to listen for TCP connections. You may also use `*` meaning "listen on all addresses". When not set, only Unix socket connections are accepted.

Addresses can be specified numerically (IPv4/IPv6) or by name.

Default: not set

##### `listen_port`

Which port to listen on. Applies to both TCP and Unix sockets.

Default: 6432

##### `unix_socket_dir`

Specifies location for Unix sockets. Applies to both listening socket and server connections. If set to an empty string, Unix sockets are disabled. A value that starts with `@` specifies that a Unix socket in the abstract namespace should be created (currently supported on Linux and Windows).

For online reboot (`-R`) to work, a Unix socket needs to be configured, and it needs to be in the file-system namespace.

Default: `/tmp` (empty on Windows)

##### `unix_socket_mode`

File system mode for Unix socket. Ignored for sockets in the abstract namespace. Not supported on Windows.

Default: 0777

##### `unix_socket_group`

Group name to use for Unix socket. Ignored for sockets in the abstract namespace. Not supported on Windows.

Default: not set

user

If set, specifies the Unix user to change to after startup. Works only if pgbouncer is started as root or if it's already running as given user.

Not supported on Windows.

Default: not set

auth\_file

The name of the file to load user names and passwords from. See [the section called "Authentication File Format"](#) for details.

Default: not set

auth\_hba\_file

HBA configuration file to use when [auth\\_type](#) is hba.

Default: not set

auth\_type

How to authenticate users.

pam

Pluggable Authentication Modules (PAM) method is used to authenticate users, [auth\\_file](#) is ignored. This method is not compatible with databases using the [auth\\_user](#) option. The service name reported to PAM is `pgbouncer`. PAM is not supported in the HBA configuration file.

hba

The actual authentication type is loaded from [auth\\_hba\\_file](#). This allows different authentication methods for different access paths, for example: connection over Unix socket uses `peer` authentication method, connections over TCP must use TLS.

cert

The client must connect over TLS connection with a valid client certificate. The user name is then taken from the `CommonName` field from the certificate.

md5

Use MD5-based password check. This is the default authentication method. [auth\\_file](#) may contain both MD5-encrypted and plain-text passwords. If `md5` is configured and a user has a SCRAM secret, then SCRAM authentication is used automatically instead.

scram-sha-256

Use password check with SCRAM-SHA-256. [auth\\_file](#) has to contain SCRAM secrets or plain-text passwords. Note that SCRAM secrets can only be used for verifying the password of a client but not for logging into a server. To be able to use SCRAM on server connections, use plain-text passwords.

plain

The clear-text password is sent over the wire. Deprecated.

trust

No authentication is done. The user name must still exist in [auth\\_file](#).

any

Like the `trust` method, but the user name given is ignored. Requires that all databases are configured to log in as a specific user. Additionally, the console database allows any user to log in as admin.

auth\_query

Query to load user's password from database.

Direct access to `pg_shadow` requires admin rights. It's preferable to use a non-superuser that calls a `SECURITY DEFINER` function instead.

Note that the query is run inside the target database. So if a function is used, it needs to be installed into each database.

Default: `SELECT username, passwd FROM pg_shadow WHERE username=$1`

auth\_user

If `auth_user` is set, then any user not specified in `auth_file` will be queried through the `auth_query` query from `pg_shadow` in the database, using `auth_user`. The password of `auth_user` will be taken from `auth_file`. (If `auth_user` does not require a password, then it does not need to be defined in `auth_file`.)

Direct access to `pg_shadow` requires admin rights. It's preferable to use a non-superuser that calls a `SECURITY DEFINER` function instead.

Default: not set

pool\_mode

Specifies when a server connection can be reused by other clients.

session

Server is released back to pool after client disconnects. Default.

transaction

Server is released back to pool after transaction finishes.

statement

Server is released back to pool after query finishes. Transactions spanning multiple statements are disallowed in this mode.

max\_client\_conn

Maximum number of client connections allowed. When increased, the file descriptor limits should also be increased. Note that the actual number of file descriptors used is more than `max_client_conn`. If each user connects under its own username to the server, the theoretical maximum used is:

`max_client_conn + (max pool_size * total databases * total users)`

If a database user is specified in the connection string (all users connect under the same user name), the theoretical maximum is:

`max_client_conn + (max pool_size * total databases)`

The theoretical maximum should be never reached, unless somebody deliberately crafts a special load for it. Still, it means you should set the number of file descriptors to a safely high number.

Search for `ulimit` in your favorite shell man page. Note: `ulimit` does not apply in a Windows environment.

Default: 100

`default_pool_size`

How many server connections to allow per user/database pair. Can be overridden in the per-database configuration.

Default: 20

`min_pool_size`

Add more server connections to pool if below this number. Improves behavior when usual load suddenly comes back after a period of total inactivity. The value is effectively capped at the pool size.

Default: 0 (disabled)

`reserve_pool_size`

How many additional connections to allow to a pool (see [reserve\\_pool\\_timeout](#)). The 0 value disables this parameter.

Default: 0 (disabled)

`reserve_pool_timeout`

If a client has not been serviced in this many seconds, pgbouncer enables use of additional connections from the reserve pool. The 0 value disables this parameter.

Default: 5.0

`max_db_connections`

Do not allow more than this many server connections per database (regardless of user). This considers the pgbouncer database that the client has connected to, not the Postgres Pro database of the outgoing connection. This can also be set per database in the `[databases]` section.

Note that when you hit the limit, closing a client connection to one pool will not immediately allow a server connection to be established for another pool, because the server connection for the first pool is still open. Once the server connection closes (due to idle timeout), a new server connection will immediately be opened for the waiting pool.

Default: 0 (unlimited)

`max_user_connections`

Do not allow more than this many server connections per user (regardless of database). This considers the pgbouncer user that is associated with a pool, which is either the user specified for the server connection or in absence of that the user the client has connected as. This can also be set per user in the `[users]` section.

Note that when you hit the limit, closing a client connection to one pool will not immediately allow a server connection to be established for another pool, because the server connection for the first pool is still open. Once the server connection closes (due to idle timeout), a new server connection will immediately be opened for the waiting pool.

Default: 0 (unlimited)

`server_round_robin`

By default, pgbouncer reuses server connections in LIFO (last-in, first-out) manner, so that few connections get the most load. This gives best performance if you have a single server serving a database. But if there is TCP round-robin behind a database IP address, then it is better if pgbouncer also uses connections in that manner, thus achieving uniform load.

Default: 0

`ignore_startup_parameters`

By default, `pgbouncer` allows only parameters it can keep track of in startup packets: `client_encoding`, `datestyle`, `timezone` and `standard_conforming_strings`.

All other parameters will raise an error. To allow other parameters, they can be specified here, so that `pgbouncer` knows that they are handled by the admin and it can ignore them.

Default: empty

`disable_pgexec`

Disable Simple Query protocol (PQexec). Unlike Extended Query protocol, Simple Query allows multiple queries in one packet, which allows some classes of SQL-injection attacks. Disabling it can improve security. Obviously this means only clients that exclusively use the Extended Query protocol will stay working.

Default: 0

`application_name_add_host`

Add the client host address and port to the application name setting set on connection start. This helps in identifying the source of bad queries, etc. This logic applies only on start of connection. If `application_name` is later changed with `SET`, `pgbouncer` does not change it again.

Default: 0

`conffile`

Show location of current configuration file. Changing it will make `pgbouncer` use another configuration file for next `RELOAD / SIGHUP`.

Default: file from command line

`service_name`

Used on win32 service registration.

Default: `pgbouncer`

`job_name`

Alias for `service_name`.

`stats_period`

Sets how often the averages shown in various `SHOW` commands are updated and how often aggregated statistics are written to the log (but see `log_stats`). [seconds]

Default: 60

### Log Settings

`syslog`

Toggles syslog on/off. On Windows, the event log is used instead.

Default: 0

`syslog_ident`

Under what name to send logs to syslog.

Default: `pgbouncer` (program name)

`syslog_facility`

Under what facility to send logs to syslog. Possibilities: `auth`, `authpriv`, `daemon`, `user`, `local0-7`.

Default: `daemon`

`log_connections`

Log successful logins.

Default: `1`

`log_disconnections`

Log disconnections with reasons.

Default: `1`

`log_pooler_errors`

Log error messages the pooler sends to clients.

Default: `1`

`log_stats`

Write aggregated statistics into the log, every `stats_period`. This can be disabled if external monitoring tools are used to grab the same data from `SHOW` commands.

Default: `1`

`verbose`

Increase verbosity. Mirrors the `-v` switch on the command line. Using `-v -v` on the command line is the same as `verbose=2`.

Default: `0`

### Console Access Control

`admin_users`

Comma-separated list of database users that are allowed to connect and run all commands on the console. Ignored when `auth_type` is `any`, in which case any user name is allowed in as admin.

Default: empty

`stats_users`

Comma-separated list of database users that are allowed to connect and run read-only queries on the console. That means all `SHOW` commands except `SHOW FDS`.

Default: empty

### Connection Sanity Checks, Timeouts

`server_reset_query`

Query sent to server on connection release, before making it available to other clients. At that moment no transaction is in progress so it should not include `ABORT` or `ROLLBACK`.

The query is supposed to clean any changes made to the database session so that the next client gets the connection in a well-defined state. The default is `DISCARD ALL` which cleans everything, but that leaves the next client no pre-cached state. It can be made lighter, e.g. `DEALLOCATE ALL` to just drop prepared statements, if the application does not break when some state is kept around.

When transaction pooling is used, the `server_reset_query` is not used, as clients must not use any session-based features as each transaction ends up in a different connection and thus gets a different session state.

Default: DISCARD ALL

`server_reset_query_always`

Whether `server_reset_query` should be run in all pooling modes. When this setting is off (default), the `server_reset_query` will be run only in pools that are in sessions-pooling mode. Connections in transaction-pooling mode should not have any need for a reset query.

This setting is for working around broken setups that run applications that use session features over a transaction-pooled pgbouncer. It changes non-deterministic breakage to deterministic breakage: clients always lose their state after each transaction.

Default: 0

`server_check_delay`

How long to keep released connections available for immediate re-use, without running sanity-check queries on it. If 0 then the query is always run.

Default: 30.0

`server_check_query`

Simple do-nothing query to check if the server connection is alive.

If an empty string, then sanity checking is disabled.

Default: SELECT 1;

`server_fast_close`

Disconnect a server in session pooling mode immediately or after the end of the current transaction if it is in `close_needed` mode (set by `RECONNECT`, `RELOAD` that changes connection settings, or DNS change), rather than waiting for the session end. In statement or transaction pooling mode, this has no effect since that is the default behavior there.

If because of this setting a server connection is closed before the end of the client session, the client connection is also closed. This ensures that the client notices that the session has been interrupted.

This setting makes connection configuration changes take effect sooner if session pooling and long-running sessions are used. The downside is that client sessions are liable to be interrupted by a configuration change, so client applications will need logic to reconnect and reestablish session state. But note that no transactions will be lost, because running transactions are not interrupted, only idle sessions.

Default: 0

`server_lifetime`

The pooler will close an unused server connection that has been connected longer than this. Setting it to 0 means the connection is to be used only once, then closed. [seconds]

Default: 3600.0

`server_idle_timeout`

If a server connection has been idle more than this many seconds it will be dropped. If 0 then timeout is disabled. [seconds]

Default: 600.0

`server_connect_timeout`

If connection and login won't finish in this amount of time, the connection will be closed. [seconds]

Default: 15.0

`server_login_retry`

If login failed, because of failure from `connect()` or authentication that pooler waits this much before retrying to connect. [seconds]

Default: 15.0

`client_login_timeout`

If a client connects but does not manage to log in in this amount of time, it will be disconnected. Mainly needed to avoid dead connections stalling `SUSPEND` and thus online restart. [seconds]

Default: 60.0

`autodb_idle_timeout`

If the automatically created (via `"*`) database pools have been unused this many seconds, they are freed. The negative aspect of that is that their statistics are also forgotten. [seconds]

Default: 3600.0

`dns_max_ttl`

How long the DNS lookups can be cached. If a DNS lookup returns several answers, pgbouncer will robin-between them in the meantime. The actual DNS TTL is ignored. [seconds]

Default: 15.0

`dns_nxdomain_ttl`

How long error and NXDOMAIN DNS lookups can be cached. [seconds]

Default: 15.0

`dns_zone_check_period`

Period to check if a zone serial has changed.

pgbouncer can collect DNS zones from host names (everything after first dot) and then periodically check if the zone serial changes. If it notices changes, all host names under that zone are looked up again. If any host IP changes, it's connections are invalidated.

Default: 0.0 (disabled)

`resolv_conf`

The location of a custom `resolv.conf` file. This is to allow specifying custom DNS servers and perhaps other name resolution options, independent of the global operating system configuration.

The parsing of the file is done by the DNS backend library, not pgbouncer, so see the library's documentation for details on allowed syntax and directives.

Default: empty (use operating system defaults)

### TLS Settings

`client_tls_sslmode`

TLS mode to use for connections from clients. TLS connections are disabled by default. When enabled, `client_tls_key_file` and `client_tls_cert_file` must be also configured to set up the key and certificate pgbouncer uses to accept client connections.

disable

Plain TCP. If client requests TLS, it's ignored. Default.

allow

If client requests TLS, it is used. If not, plain TCP is used. If the client presents a client certificate, it is not validated.

prefer

Same as allow.

require

The client must use TLS. If not, the client connection is rejected. If the client presents a client certificate, it is not validated.

verify-ca

Client must use TLS with valid client certificate.

verify-full

Same as verify-ca.

client\_tls\_key\_file

Private key for pgbouncer to accept client connections.

Default: not set

client\_tls\_cert\_file

Certificate for private key. Clients can validate it.

Default: not set

client\_tls\_ca\_file

Root certificate file to validate client certificates.

Default: not set

client\_tls\_protocols

Which TLS protocol versions are allowed. Allowed values: `tlsv1.0`, `tlsv1.1`, `tlsv1.2`, `tlsv1.3`. Shortcuts: `all` (`tlsv1.0,tlsv1.1,tlsv1.2,tlsv1.3`), `secure` (`tlsv1.2,tlsv1.3`), `legacy` (`all`).

Default: `secure`

client\_tls\_ciphers

Allowed TLS ciphers, in OpenSSL syntax. Shortcuts: `default/secure`, `compat/legacy`, `insecure/all`, `normal`, `fast`.

Only connections using TLS version 1.2 and lower are affected. There is currently no setting that controls the cipher choices used by TLS version 1.3 connections.

Default: `fast`

client\_tls\_ecdhcurve

Elliptic Curve name to use for ECDH key exchanges.

Allowed values: `none` (DH is disabled), `auto` (256-bit ECDH), `curve name`.

Default: auto

client\_tls\_dheparams

DHE key exchange type.

Allowed values: none (DH is disabled), auto (2048-bit DH), legacy (1024-bit DH).

Default: auto

server\_tls\_sslmode

TLS mode to use for connections to Postgres Pro servers. TLS connections are disabled by default.

disable

Plain TCP. TLS is not even requested from the server. Default.

prefer

TLS connection is always requested first from Postgres Pro, when refused connection will be established over plain TCP. Server certificate is not validated.

require

Connection must go over TLS. If server rejects it, plain TCP is not attempted. Server certificate is not validated.

verify-ca

Connection must go over TLS and server certificate must be valid according to [server\\_tls\\_ca\\_file](#). Server host name is not checked against certificate.

verify-full

Connection must go over TLS and server certificate must be valid according to [server\\_tls\\_ca\\_file](#). Server host name must match certificate information.

server\_tls\_ca\_file

Root certificate file to validate Postgres Pro server certificates.

Default: not set

server\_tls\_key\_file

Private key for pgbouncer to authenticate against Postgres Pro server.

Default: not set

server\_tls\_cert\_file

Certificate for private key. Postgres Pro server can validate it.

Default: not set

server\_tls\_protocols

Which TLS protocol versions are allowed. Allowed values: tlsv1.0, tlsv1.1, tlsv1.2, tlsv1.3. Shortcuts: all (tlsv1.0,tlsv1.1,tlsv1.2,tlsv1.3), secure (tlsv1.2,tlsv1.3), legacy (all).

Default: secure

server\_tls\_ciphers

Allowed TLS ciphers, in OpenSSL syntax. Shortcuts: default/secure, compat/legacy, insecure/all, normal, fast.

Only connections using TLS version 1.2 and lower are affected. There is currently no setting that controls the cipher choices used by TLS version 1.3 connections.

Default: `fast`

### Dangerous Timeouts

Setting the following timeouts can cause unexpected errors.

`query_timeout`

Queries running longer than that are canceled. This should be used only with slightly smaller server-side `statement_timeout`, to apply only for network problems. [seconds]

Default: 0.0 (disabled)

`query_wait_timeout`

Maximum time queries are allowed to spend waiting for execution. If the query is not assigned to a server during that time, the client is disconnected. This is used to prevent unresponsive servers from grabbing up connections. [seconds]

It also helps when the server is down or database rejects connections for any reason. If this is disabled, clients will be queued indefinitely.

Default: 120

`client_idle_timeout`

Client connections idling longer than this many seconds are closed. This should be larger than the client-side connection lifetime settings, and only used for network problems. [seconds]

Default: 0.0 (disabled)

`idle_transaction_timeout`

If a client has been in the “idle in transaction” state longer, it will be disconnected. [seconds]

Default: 0.0 (disabled)

`suspend_timeout`

How many seconds to wait for buffer flush during `SUSPEND` or `reboot (-R)`. A connection is dropped if the flush does not succeed.

Default: 10

### Low-Level Network Settings

`pkt_buf`

Internal buffer size for packets. Affects size of TCP packets sent and general memory usage. Actual libpq packets can be larger than this, so no need to set it large.

Default: 4096

`max_packet_size`

Maximum size for Postgres Pro packets that `pgbouncer` allows through. One packet is either one query or one result set row. Full result set can be larger.

Default: 2147483647

`listen_backlog`

The value of the `backlog` argument for `listen()`. Determines how many new unanswered connection attempts are kept in queue. When the queue is full, further new connections are dropped.

Default: 128

sbuf\_loopcnt

How many times to process data on one connection, before proceeding. Without this limit, one connection with a big result set can stall pgbouncer for a long time. One loop processes one `pkt_buf` amount of data. 0 means no limit.

Default: 5

so\_reuseport

Specifies whether to set the socket option `SO_REUSEPORT` on TCP listening sockets. On some operating systems, this allows running multiple pgbouncer instances on the same host listening on the same port and having the kernel distribute the connections automatically. This option is a way to get pgbouncer to use more CPU cores. (pgbouncer is single-threaded and uses one CPU core per instance.)

This setting has the desired effect on Linux. On systems that don't support the socket option at all, turning this setting on will result in an error.

Each pgbouncer instance on the same host needs different settings for at least `unix_socket_dir` and `pidfile`, as well as `logfile` if that is used. Also note that if you make use of this option, you can no longer connect to a specific pgbouncer instance via TCP/IP, which might have implications for monitoring and metrics collection.

Default: 0

tcp\_defer\_accept

For details on this and other TCP options, please see `man 7 tcp`.

Default: 45 on Linux, otherwise 0

tcp\_socket\_buffer

Default: not set

tcp\_keepalive

Turns on basic keepalive with OS defaults.

On Linux, the system defaults are **tcp\_keepidle=7200**, **tcp\_keepintvl=75**, **tcp\_keepcnt=9**. They are probably similar on other operating systems.

Default: 1

tcp\_keepcnt

Default: not set

tcp\_keepidle

Default: not set

tcp\_keepintvl

Default: not set

tcp\_user\_timeout

Sets the `TCP_USER_TIMEOUT` socket option. This specifies the maximum amount of time in milliseconds that transmitted data may remain unacknowledged before the TCP connection is forcibly closed. If set to 0, then operating system's default is used.

This is currently only supported on Linux.

Default: 0

#### Section [databases]

This contains key=value pairs where key will be taken as a database name and value as a libpq connect-string style list of key=value pairs. As actual libpq is not used, not all features from libpq can be used (service=, .pgpass).

The database name can contain characters `_0-9A-Za-z` without quoting. Names that contain other chars need to be quoted with standard SQL ident quoting: double quotes where `"` is taken as single quote.

The database name `pgbouncer` is reserved for the admin console and cannot be used as a key here.

\* acts as fallback database: if the exact name does not exist, its value is taken as connection string for the requested database. For example, if there is the following entry (and no other overriding entries):

```
* = host=foo
```

In this case, a connection to `pgbouncer` specifying a database `bar` will effectively behave as if the following entry exists (taking advantage of the default for `dbname` being the client-side database name):

```
bar = host=foo dbname=bar
```

Such automatically created database entries are cleaned up if they stay idle longer than the time specified by the `autodb_idle_timeout` parameter.

`dbname`

Destination database name.

Default: same as client-side database name

`host`

Host name or IP address to connect to. Host names are resolved at connection time, the result is cached per `dns_max_ttl` parameter. When a host name's resolution changes, existing server connections are automatically closed when they are released (according to the pooling mode), and new server connections immediately use the new resolution. If DNS returns several results, they are used in round-robin manner.

If the value begins with `/`, then a Unix socket in the file-system namespace is used. If the value begins with `@`, then a Unix socket in the abstract namespace is used.

Default: not set, meaning to use a Unix socket

`port`

Default: 5432

`user`

If `user=` is set, all connections to the destination database will be done with the specified user, meaning that there will be only one pool for this database.

Otherwise `pgbouncer` logs into the destination database with the client user name, meaning that there will be one pool per user.

`password`

If no password is specified here, the password from the `auth_file` or `auth_query` will be used.

`auth_user`

Override of the global `auth_user` setting, if specified.

`pool_size`

Set the maximum size of pools for this database. If not set, the `default_pool_size` is used.

`min_pool_size`

Set the minimum pool size for this database. If not set, the global `min_pool_size` is used.

`reserve_pool`

Set additional connections for this database. If not set, `reserve_pool_size` is used.

`connect_query`

Query to be executed after a connection is established, but before allowing the connection to be used by any clients. If the query raises errors, they are logged but ignored otherwise.

`pool_mode`

Set the pool mode specific to this database. If not set, the default `pool_mode` is used.

`max_db_connections`

Configure a database-wide maximum (i.e. all pools within the database will not have more than this many server connections).

`client_encoding`

Ask specific `client_encoding` from server.

`datestyle`

Ask specific `datestyle` from server.

`timezone`

Ask specific `timezone` from server.

#### **Section [users]**

This contains key=value pairs where the key will be taken as a user name and the value as a libpq connect-string style list of key=value pairs of configuration settings specific for this user. Only a few settings are available here.

`pool_mode`

Set the pool mode to be used for all connections from this user. If not set, the database or default `pool_mode` is used.

`max_user_connections`

Configure a maximum for the user (i.e. all pools with the user will not have more than this many server connections).

#### **Include Directive**

The `pgbouncer` configuration file can contain include directives, which specify another configuration file to read and process. This allows splitting the configuration file into physically separate parts. The include directives look like this:

```
%include filename
```

If the file name is not absolute path it is taken as relative to current working directory.

#### **Authentication File Format**

This section describes the format of the file specified by the `auth_file` setting. It is a text file in the following format:

```
"username1" "password" ...
"username2" "md5abcdef012342345" ...
"username2" "SCRAM-SHA-256$iterations:salt$storedkey:serverkey"
```

There should be at least two fields, surrounded by double quotes. The first field is the user name and the second is either a plain-text, a MD5-hashed password, or a SCRAM secret. pgbouncer ignores the rest of the line. Double quotes in a field value can be escaped by writing two double quotes.

Postgres Pro MD5-hashed password format:

```
"md5" + md5(password + username)
```

```
So user admin with password 1234 will have MD5-hashed password
md545f2603610af569b6155c45067268c6b.
```

Postgres Pro SCRAM secret format:

```
SCRAM-SHA-256$iterations:salt$storedkey:serverkey
```

The passwords or secrets stored in the authentication file serve two purposes. First, they are used to verify the passwords of incoming client connections, if a password-based authentication method is configured. Second, they are used as the passwords for outgoing connections to the backend server, if the backend server requires password-based authentication (unless the password is specified directly in the database's connection string). The latter works if the password is stored in plain text or MD5-hashed. SCRAM secrets can only be used for logging into a server if the client authentication also uses SCRAM, the pgbouncer database definition does not specify a user name, and the SCRAM secrets are identical in pgbouncer and the Postgres Pro server (same salt and iterations, not merely the same password). This is due to an inherent security property of SCRAM: the stored SCRAM secret cannot by itself be used for deriving login credentials.

The authentication file can be written by hand, but it's also useful to generate it from some other list of users and passwords. See `./etc/mkauth.py` for a sample script to generate the authentication file from the `pg_shadow` system table.

Alternatively, use `auth_query` instead of `auth_file` to avoid having to maintain a separate authentication file.

### HBA File Format

The location of the HBA file is specified by the setting `auth_hba_file`. It is only used if `auth_type` is set to `hba`.

The file follows the format of the Postgres Pro `pg_hba.conf` file described in [Section 19.1](#).

- **Supported record types:** `local`, `host`, `hostssl`, `hostnossl`.
- **Database field:** Supports `all`, `sameuser`, `@file`, multiple names. Not supported: `replication`, `samerole`, `samegroup`.
- **User name field:** Supports `all`, `@file`, multiple names. Not supported: `+groupname`.
- **Address field:** Supports `IPv4`, `IPv6`. Not supported: DNS names, domain prefixes.
- **Auth-method field:** Only methods supported by pgbouncer's `auth_type` are supported, except any and `pam`, which only work globally. User name map (`map=`) parameter is not supported.

### Example

Minimal config:

```
[databases]
template1 = host=localhost dbname=template1 auth_user=someuser

[pgbouncer]
pool_mode = session
listen_port = 6432
```

```
listen_addr = localhost
auth_type = md5
auth_file = users.txt
logfile = pgbouncer.log
pidfile = pgbouncer.pid
admin_users = someuser
stats_users = stat_collector
```

### Database defaults:

```
[databases]

; foodb over Unix socket
foodb =

; redirect bardb to bazdb on localhost
bardb = host=localhost dbname=bazdb

; access to destination database will go with single user
forcedb = host=localhost port=300 user=baz password=foo client_encoding=UNICODE
datestyle=ISO
```

### Example of a secure function for auth\_query:

```
CREATE OR REPLACE FUNCTION pgbouncer.user_lookup(in i_username text, out uname text,
out phash text)
RETURNS record AS $$
BEGIN
    SELECT username, passwd FROM pg_catalog.pg_shadow
    WHERE username = i_username INTO uname, phash;
    RETURN;
END;
$$ LANGUAGE plpgsql SECURITY DEFINER;
REVOKE ALL ON FUNCTION pgbouncer.user_lookup(text) FROM public, pgbouncer;
GRANT EXECUTE ON FUNCTION pgbouncer.user_lookup(text) TO pgbouncer;
```

## pg\_filedump

pg\_filedump — display formatted contents of a Postgres Pro heap, index, or control file

### Synopsis

```
pg_filedump [option...] [file]
```

### Description

pg\_filedump is a utility to format Postgres Pro heap/index/control files into a human-readable form. You can format/dump the files several ways, as listed in the [Options](#) section, as well as dump a straight binary. The type of file (heap/index) can usually be determined automatically by the content of the blocks within the file. However, to format a `pg_control` file you must use the `-c` option. The default is to format the entire file using the block size listed in block 0 and display block relative addresses. These defaults can be modified using run-time options. Some options may seem strange but they are there for a reason. For example, block size. It is there because if the header of block 0 is corrupt, you need a method of forcing a block size.

### Installation

pg\_filedump is provided with Postgres Pro as a separate pre-built package `pg-filedump-std-13` (for the detailed installation instructions, see [Chapter 16](#)).

### Options

Defaults are: relative addressing, range of the entire file, block size as listed on block 0 in the file.

The following options are valid for heap and index files:

`-a`  
Display absolute addresses when formatting. Block header information is always block-relative.

`-b`  
Display binary block images within a range. The option will turn off all formatting options.

`-d`  
Display formatted block content dump. The option will turn off all other formatting options.

`-D attrlist`  
Decode tuples using given comma-separated list of types. The list of supported types:

```
bigint  
bigserial  
bool  
char  
charN — char(n)  
date  
float  
float4  
float8  
int  
json  
macaddr  
name  
numeric  
oid  
real
```

serial  
smallint  
smallserial  
text  
time  
timestamp  
timetz  
uuid  
varchar  
varcharN — varchar(n)  
xid  
xml  
~ — ignore all attributes left in a tuple

- f  
Display formatted block content dump along with interpretation.
- h  
Display help.
- i  
Display interpreted item details.
- k  
Verify block checksums.
- o  
Do not dump old values.
- R *startblock* [*endblock*]  
Display specific block ranges within the file. Blocks are indexed from 0. *startblock*: block to start at. *endblock*: block to end at. A *startblock* without an *endblock* will format a single block.
- s *segsize*  
Force segment size to *segsize*.
- t  
Dump TOAST files.
- v  
Output additional information about TOAST relations.
- n *segnumber*  
Force segment number to *segnumber*.
- S *blocksize*  
Force block size to *blocksize*.
- x  
Force interpreted formatting of block items as index items.
- y  
Force interpreted formatting of block items as heap items.

The following options are valid for control files:

`-c`

Interpret the file listed as a control file.

`-f`

Display formatted content dump along with interpretation.

`-S blocksize`

Force block size to *blocksize*.

Additional parameters:

`-m`

Interpret file as `pg_filenode.map` file and print contents. All other options will be ignored.

In most cases, it is recommended to use the `-i` and `-f` options to get the most useful dump output.

## pgpro\_controldata

pgpro\_controldata — display control information of a PostgreSQL/Postgres Pro database cluster and compatibility information for a cluster and/or server

### Synopsis

```
pgpro_controldata [option...]
```

### Description

pgpro\_controldata prints control information, such as the catalog version, initialized by `initdb` command of any PostgreSQL/Postgres Pro server. It also shows information about write-ahead logging and checkpoint processing. This information is cluster-wide and not specific to any database.

pgpro\_controldata also helps to check compatibility between PostgreSQL/Postgres Pro database servers and clusters. It can print server or cluster parameters that can affect the compatibility and check whether a cluster and server are compatible by comparing those parameters.

### Options

pgpro\_controldata accepts the following command-line arguments. If no arguments are specified, pgpro\_controldata just prints the control information like [pg\\_controldata](#) does. Note that compatibility-related command-line arguments `-P` and `-S` specified together work the same way as `-C`.

#### General-Purpose

`-B`  
`--bindir`  
Specifies the PostgreSQL/Postgres Pro executable directory, needed to get server compatibility parameters.

`-D datadir`  
`--pgdata=datadir`  
Specifies the file system location of the database configuration files. If this option is omitted, the environment variable `PGDATA` is used.

`-V`  
`--version`  
Print the pgpro\_controldata version, then exit.

`-?`  
`--help`  
Show help about pgpro\_controldata command-line arguments, then exit.

#### Compatibility-Related

`-C`  
`--compatibility-check`  
Display all parameters that can affect compatibility between the specified server and cluster and check whether they are compatible.

Use the `-D` option or the environment variable `PGDATA` to provide the path to the data directory, where read access is required.

If the `-B` option is omitted, the current server is assumed.

The cluster data and the server must have the same byte order and architecture type for this option to work correctly.

`-P`  
`--cluster-compatibility-params`

Display all parameters of the specified cluster that can affect the compatibility.

Use the `-D` option or the environment variable `PGDATA` to provide the path to the data directory, where read access is required.

The cluster data and the server must have the same byte order and architecture type for this option to work correctly.

`-S`  
`--server-compatibility-params`

Display all parameters of the specified or current server that can affect the compatibility.

If the `-B` option is omitted, the current server is assumed.

### Environment

`PGDATA`  
Default data directory location

`PG_COLOR`  
Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

## pg\_standby

`pg_standby` — supports the creation of a Postgres Pro warm standby server

### Synopsis

```
pg_standby [option...] archivelocation nextwalfile walfilepath [restartwalfile]
```

### Description

`pg_standby` supports creation of a “warm standby” database server. It is designed to be a production-ready program, as well as a customizable template should you require specific modifications.

`pg_standby` is designed to be a waiting `restore_command`, which is needed to turn a standard archive recovery into a warm standby operation. Other configuration is required as well, all of which is described in the main server manual (see [Section 25.2](#)).

To configure a standby server to use `pg_standby`, put this into its `postgresql.conf` configuration file:

```
restore_command = 'pg_standby archiveDir %f %p %r'
```

where *archiveDir* is the directory from which WAL segment files should be restored.

If *restartwalfile* is specified, normally by using the `%r` macro, then all WAL files logically preceding this file will be removed from *archivelocation*. This minimizes the number of files that need to be retained, while preserving crash-restart capability. Use of this parameter is appropriate if the *archivelocation* is a transient staging area for this particular standby server, but *not* when the *archivelocation* is intended as a long-term WAL archive area.

`pg_standby` assumes that *archivelocation* is a directory readable by the server-owning user. If *restartwalfile* (or `-k`) is specified, the *archivelocation* directory must be writable too.

There are two ways to fail over to a “warm standby” database server when the master server fails:

#### Smart Failover

In smart failover, the server is brought up after applying all WAL files available in the archive. This results in zero data loss, even if the standby server has fallen behind, but if there is a lot of unapplied WAL it can be a long time before the standby server becomes ready. To trigger a smart failover, create a trigger file containing the word `smart`, or just create it and leave it empty.

#### Fast Failover

In fast failover, the server is brought up immediately. Any WAL files in the archive that have not yet been applied will be ignored, and all transactions in those files are lost. To trigger a fast failover, create a trigger file and write the word `fast` into it. `pg_standby` can also be configured to execute a fast failover automatically if no new WAL file appears within a defined interval.

### Options

`pg_standby` accepts the following command-line arguments:

- `-c`  
Use `cp` or `copy` command to restore WAL files from archive. This is the only supported behavior so this option is useless.
- `-d`  
Print lots of debug logging output on `stderr`.
- `-k`  
Remove files from *archivelocation* so that no more than this many WAL files before the current one are kept in the archive. Zero (the default) means not to remove any files from *archivelocation*. This

parameter will be silently ignored if *restartwalfile* is specified, since that specification method is more accurate in determining the correct archive cut-off point. Use of this parameter is *deprecated* as of PostgreSQL 8.3; it is safer and more efficient to specify a *restartwalfile* parameter. A too small setting could result in removal of files that are still needed for a restart of the standby server, while a too large setting wastes archive space.

`-r maxretries`

Set the maximum number of times to retry the copy command if it fails (default 3). After each failure, we wait for *sleeptime* \* *num\_retries* so that the wait time increases progressively. So by default, we will wait 5 secs, 10 secs, then 15 secs before reporting the failure back to the standby server. This will be interpreted as end of recovery and the standby will come up fully as a result.

`-s sleeptime`

Set the number of seconds (up to 60, default 5) to sleep between tests to see if the WAL file to be restored is available in the archive yet. The default setting is not necessarily recommended; consult [Section 25.2](#) for discussion.

`-t triggerfile`

Specify a trigger file whose presence should cause failover. It is recommended that you use a structured file name to avoid confusion as to which server is being triggered when multiple servers exist on the same system; for example `/tmp/pgsql.trigger.5432`.

`-V`

`--version`

Print the `pg_standby` version and exit.

`-w maxwaittime`

Set the maximum number of seconds to wait for the next WAL file, after which a fast failover will be performed. A setting of zero (the default) means wait forever. The default setting is not necessarily recommended; consult [Section 25.2](#) for discussion.

`-?`

`--help`

Show help about `pg_standby` command line arguments, and exit.

## Notes

`pg_standby` is designed to work with PostgreSQL 8.2 and later.

PostgreSQL 8.3 provides the `%r` macro, which is designed to let `pg_standby` know the last file it needs to keep. With PostgreSQL 8.2, the `-k` option must be used if archive cleanup is required. This option remains available in 8.3, but its use is deprecated.

PostgreSQL 8.4 provides the `recovery_end_command` option. Without this option a leftover trigger file can be hazardous.

`pg_standby` is written in C and has an easy-to-modify source code, with specifically designated sections to modify for your own needs

## Examples

On Linux or Unix systems, you might use:

```
archive_command = 'cp %p ../archive/%f'
```

```
restore_command = 'pg_standby -d -s 2 -t /tmp/pgsql.trigger.5442 ../archive %f %p %r  
2>>standby.log'
```

```
recovery_end_command = 'rm -f /tmp/pgsql.trigger.5442'
```

where the archive directory is physically located on the standby server, so that the `archive_command` is accessing it across NFS, but the files are local to the standby (enabling use of `ln`). This will:

- produce debugging output in `standby.log`
- sleep for 2 seconds between checks for next WAL file availability
- stop waiting only when a trigger file called `/tmp/pgsql.trigger.5442` appears, and perform failover according to its content
- remove the trigger file when recovery ends
- remove no-longer-needed files from the archive directory

On Windows, you might use:

```
archive_command = 'copy %p ...\\archive\\%f'
```

```
restore_command = 'pg_standby -d -s 5 -t C:\pgsql.trigger.5442 ...\archive %f %p %r  
2>>standby.log'
```

```
recovery_end_command = 'del C:\pgsql.trigger.5442'
```

Note that backslashes need to be doubled in the `archive_command`, but *not* in the `restore_command` or `recovery_end_command`. This will:

- use the `copy` command to restore WAL files from archive
- produce debugging output in `standby.log`
- sleep for 5 seconds between checks for next WAL file availability
- stop waiting only when a trigger file called `C:\pgsql.trigger.5442` appears, and perform failover according to its content
- remove the trigger file when recovery ends
- remove no-longer-needed files from the archive directory

The `copy` command on Windows sets the final file size before the file is completely copied, which would ordinarily confuse `pg_standby`. Therefore `pg_standby` waits `sleep_time` seconds once it sees the proper file size. GNUWin32's `cp` sets the file size only after the file copy is complete.

Since the Windows example uses `copy` at both ends, either or both servers might be accessing the archive directory across the network.

# Appendix H. External Projects

Postgres Pro is a complex software project, and managing the project is difficult. We have found that many enhancements to Postgres Pro can be more efficiently developed separately from the core project.

## H.1. Client Interfaces

There are only two client interfaces included in the base Postgres Pro Standard distribution:

- [libpq](#) is included because it is the primary C language interface, and because many other client interfaces are built on top of it.
- [ECPG](#) is included because it depends on the server-side SQL grammar, and is therefore sensitive to changes in Postgres Pro itself.

All other language interfaces are external projects and are distributed separately. [Table H.1](#) includes a list of some of these projects. Note that some of these packages might not be released under the same license as Postgres Pro. For more information on each language interface, including licensing terms, refer to its website and documentation.

**Table H.1. Externally Maintained Client Interfaces**

Name	Language	Comments	Website
DBD::Pg	Perl	Perl DBI driver	<a href="https://metacpan.org/release/DBD-Pg">https://metacpan.org/release/DBD-Pg</a>
JDBC	Java	Type 4 JDBC driver	<a href="https://jdbc.postgresql.org/">https://jdbc.postgresql.org/</a>
libpqxx	C++	C++ interface	<a href="https://pqxx.org/">https://pqxx.org/</a>
node-postgres	JavaScript	Node.js driver	<a href="https://node-postgres.com/">https://node-postgres.com/</a>

psqlODBC	ODBC	ODBC driver	<a href="https://odbc.postgresql.org/">https://odbc.postgresql.org/</a>
psycopg	Python	DB API 2.0-compliant	<a href="https://www.psycopg.org/">https://www.psycopg.org/</a>

## H.2. Administration Tools

There are several administration tools available for Postgres Pro. The most popular is [pgAdmin](#), and there are several commercially available ones as well.

## H.3. Procedural Languages

Postgres Pro includes several procedural languages with the base distribution: [PL/pgSQL](#), [PL/Tcl](#), [PL/Perl](#), and [PL/Python](#).

In addition, there are a number of procedural languages that are developed and maintained outside the core Postgres Pro distribution. [Table H.2](#) lists some of these packages. Note that some of these projects might not be released under the same license as Postgres Pro. For more information on each procedural language, including licensing information, refer to its website and documentation.

**Table H.2. Externally Maintained Procedural Languages**

Name	Language	Website
PL/Java	Java	<a href="https://tada.github.io/pljava/">https://tada.github.io/pljava/</a>
PL/Lua	Lua	<a href="https://github.com/pllua/pllua-ng">https://github.com/pllua/pllua-ng</a>
PL/R	R	<a href="https://github.com/postgres-plr/plr">https://github.com/postgres-plr/plr</a>
PL/sh	Unix shell	<a href="https://github.com/petere/plsh">https://github.com/petere/plsh</a>
PL/v8	JavaScript	<a href="https://github.com/plv8/plv8">https://github.com/plv8/plv8</a>

## H.4. Extensions

Postgres Pro is designed to be easily extensible. For this reason, extensions loaded into the database can function just like features that are built in. The `contrib/` directory shipped with the source code contains several extensions, which are described in [Appendix F](#). Other extensions are developed independently, like *PostGIS*. Even Postgres Pro replication solutions can be developed externally. For example, *Slony-I* is a popular master/standby replication solution that is developed independently from the core project.

---

# Appendix I. Configuring Postgres Pro for 1C Solutions

You can install and use Postgres Pro with 1C solutions in a client/server model. For optimal performance and stability, modify the following settings in the `postgresql.conf` configuration file of Postgres Pro server:

1. Increase the maximum number of allowed concurrent connections to the database server, up to 1000 connections. 1C solutions can open a large number of connections, even if not all of them are used, so it is recommended to allow not less than 500 connections.

```
max_connections = 1000
```

2. To ensure that temporary tables are handled correctly, modify the following parameters:

- Increase the buffer size for temporary tables:

```
temp_buffers = 32MB
```

- Increase the number of allowed locks of tables or indexes per transaction to 256:

```
max_locks_per_transaction = 256
```

Typically, 1C solutions use a lot of temporary tables. Every backend process usually contains multiple temporary tables. When closing a connection, Postgres Pro tries to drop all temporary tables in a single transaction, so this transaction may use a lot of locks. If the number of locks exceeds the `max_locks_per_transaction` value, the transaction will fail, leaving multiple orphaned temporary tables.

3. Enable backslash escapes in all strings, and switch off the warning about using the backslash escape symbol:

```
standard_conforming_strings = off  
escape_string_warning = off
```

4. Set the `effective_cache_size` parameter to at least half of RAM available on the system. Postgres Pro query optimizer performance depends on the amount of allocated RAM.

5. Optimize query planning using `online_analyze` and `plantuner` extensions, as follows:

- Add `online_analyze` and `plantuner` to the `shared_preload_libraries` variable.

```
shared_preload_libraries = 'online_analyze, plantuner'
```

- Enable automatic analysis of temporary tables when they are modified:

```
online_analyze.table_type = 'temporary'
```

- Tune Postgres Pro optimizer to improve planning for recently created empty tables:

```
plantuner.fix_empty_table = 'on'
```

- Suppress detailed messages from the `online_analyze` extension:

```
online_analyze.verbose = 'off'
```

---

# Appendix J. Postgres Pro Limits

Table J.1 describes various hard limits of Postgres Pro. However, practical limits, such as performance limitations or available disk space may apply before absolute hard limits are reached.

**Table J.1. Postgres Pro Limitations**

Item	Upper Limit	Comment
database size	unlimited	
number of databases	4,294,950,911	
relations per database	1,431,650,303	
relation size	32 TB	with the default <code>BLCKSZ</code> of 8192 bytes
rows per table	limited by the number of tuples that can fit onto 4,294,967,295 pages	
columns per table	1600	further limited by tuple size fitting on a single page; see note below
field size	1 GB	
identifier length	63 bytes	can be increased by recompiling Postgres Pro
indexes per table	unlimited	constrained by maximum relations per database
columns per index	32	can be increased by recompiling Postgres Pro
partition keys	32	can be increased by recompiling Postgres Pro

The maximum number of columns for a table is further reduced as the tuple being stored must fit in a single 8192-byte heap page. For example, excluding the tuple header, a tuple made up of 1600 `int` columns would consume 6400 bytes and could be stored in a heap page, but a tuple of 1600 `bigint` columns would consume 12800 bytes and would therefore not fit inside a heap page. Variable-length fields of types such as `text`, `varchar`, and `char` can have their values stored out of line in the table's TOAST table when the values are large enough to require it. Only an 18-byte pointer must remain inside the tuple in the table's heap. For shorter length variable-length fields, either a 4-byte or 1-byte field header is used and the value is stored inside the heap tuple.

Columns that have been dropped from the table also contribute to the maximum column limit. Moreover, although the dropped column values for newly created tuples are internally marked as null in the tuple's null bitmap, the null bitmap also occupies space.

---

# Appendix K. Demo Database “Airlines”

This is an overview of a demo database for Postgres Pro. This appendix describes the database schema, which consists of eight tables and several views. The subject field of this database is airline flights in Russia. You can download the database from [our website](#). See [Section K.1](#) for details.

**Figure K.1. Airlines in Russia**

You can use this database for various purposes, such as:

- learning SQL language on your own
- preparing books, manuals, and courses on SQL
- showing Postgres Pro features in stories and articles

When developing this demo database, we pursued several goals:

- Database schema must be simple enough to be understood without extra explanations.
- At the same time, database schema must be complex enough to allow writing meaningful queries.
- The database must contain true-to-life data that will be interesting to work with.

This demo database is distributed under the [PostgreSQL license](#).

You can send us your feedback to [edu@postgrespro.ru](mailto:edu@postgrespro.ru).

## K.1. Installation

The demo database is available at [edu.postgrespro.com](http://edu.postgrespro.com) in three flavors, which differ only in the data size:

- [demo-small-en.zip](#) (21 MB) — flight data for one month (DB size is about 300 MB)
- [demo-medium-en.zip](#) (62 MB) — flight data for three months (DB size is about 700 MB)
- [demo-big-en.zip](#) (232 MB) — flight data for one year (DB size is about 2.5 GB)

The small database is good for writing queries, and it will not take up much disk space. The large database can help you understand the query behavior on large data volumes and consider query optimization.

The files include an SQL script that creates the `demo` database and fills it with data (virtually, it is a backup copy created with the `pg_dump` utility). The owner of the `demo` database will be the DBMS user who runs the script. For example, to create the small database, run the script as the user `postgres` by means of `psql`:

```
psql -f demo_small_YYYYMMDD.sql -U postgres
```

Note that if the `demo` database already exists, it will be deleted and recreated!

## K.2. Schema Diagram

Figure K.2. Bookings Schema Diagram

## K.3. Schema Description

The main entity is a booking (`bookings`).

One booking can include several passengers, with a separate ticket (`tickets`) issued to each passenger. A ticket has a unique number and includes information about the passenger. As such, the passenger is not a separate entity. Both the passenger's name and identity document number can change over time, so it is impossible to uniquely identify all the tickets of a particular person; for simplicity, we can assume that all passengers are unique.

The ticket includes one or more flight segments (`ticket_flights`). Several flight segments can be included into a single ticket if there are no non-stop flights between the points of departure and destination (connecting flights), or if it is a round-trip ticket. Although there is no constraint in the schema, it is assumed that all tickets in the booking have the same flight segments.

Each flight (`flights`) goes from one airport (`airports`) to another. Flights with the same flight number have the same points of departure and destination, but differ in departure date.

At flight check-in, the passenger is issued a boarding pass (`boarding_passes`), where the seat number is specified. The passenger can check in for the flight only if this flight is included into the ticket. The flight-seat combination must be unique to avoid issuing two boarding passes for the same seat.

The number of seats (`seats`) in the aircraft and their distribution between different travel classes depends on the model of the aircraft (`aircrafts`) performing the flight. It is assumed that every aircraft model has only one cabin configuration. Database schema does not check that seat numbers in boarding passes have the corresponding seats in the aircraft (such verification can be done using table triggers, or at the application level).

## K.4. Schema Objects

### K.4.1. List of Relations

Name	Type	Small	Medium	Big	Description
<code>aircrafts</code>	view				Aircraft
<code>aircrafts_data</code>	table	16 kB	16 kB	16 kB	Aircraft (translations)
<code>airports</code>	view				Airports
<code>airports_data</code>	table	56 kB	56 kB	56 kB	Airports (translations)
<code>boarding_passes</code>	table	31 MB	102 MB	427 MB	Boarding passes
<code>bookings</code>	table	13 MB	30 MB	105 MB	Bookings
<code>flights</code>	table	3 MB	6 MB	19 MB	Flights
<code>flights_v</code>	view				Flights
<code>routes</code>	view				Routes
<code>seats</code>	table	88 kB	88 kB	88 kB	Seats
<code>ticket_flights</code>	table	64 MB	145 MB	516 MB	Flight segments
<code>tickets</code>	table	47 MB	107 MB	381 MB	Tickets

### K.4.2. View `bookings.aircrafts`

Each aircraft model is identified by its three-digit code (`aircraft_code`). The view also includes the name of the aircraft model (`model`) and the maximal flying distance, in kilometers (`range`).

The value of the `model` field is selected according to the chosen language. See [Section K.4.15](#) for details.

Column	Type	Modifiers	Description
<code>aircraft_code</code>	<code>char(3)</code>	<code>not null</code>	Aircraft code, IATA
<code>model</code>	<code>text</code>	<code>not null</code>	Aircraft model
<code>range</code>	<code>integer</code>	<code>not null</code>	Maximal flying distance, km

View definition:

```
SELECT ml.aircraft_code,
       ml.model ->> lang() AS model,
       ml.range
FROM aircrafts_data ml;
```

### K.4.3. Table `bookings.aircrafts_data`

This is the base table for the `aircrafts` view. The `model` field of this table contains translations of aircraft models to different languages, in the JSONB format. In most cases, this table is not supposed to be used directly.

Column	Type	Modifiers	Description
<code>aircraft_code</code>	<code>char(3)</code>	<code>not null</code>	Aircraft code, IATA

```

model          | jsonb   | not null    | Aircraft model
range         | integer | not null    | Maximal flying distance, km

```

Indexes:

```
PRIMARY KEY, btree (aircraft_code)
```

Check constraints:

```
CHECK (range > 0)
```

Referenced by:

```

TABLE "flights" FOREIGN KEY (aircraft_code)
REFERENCES aircrafts_data(aircraft_code)
TABLE "seats" FOREIGN KEY (aircraft_code)
REFERENCES aircrafts_data(aircraft_code) ON DELETE CASCADE

```

#### K.4.4. View `bookings.airports`

An airport is identified by a three-letter code (`airport_code`) and has a name (`airport_name`).

There is no separate entity for the city, but there is a city name (`city`) to identify the airports of the same city. The view also includes coordinates (`coordinates`) and the time zone (`timezone`).

The values of the `airport_name` and `city` fields are selected according to the chosen language. See [Section K.4.15](#) for details.

Column	Type	Modifiers	Description
<code>airport_code</code>	<code>char(3)</code>	<code>not null</code>	Airport code
<code>airport_name</code>	<code>text</code>	<code>not null</code>	Airport name
<code>city</code>	<code>text</code>	<code>not null</code>	City
<code>coordinates</code>	<code>point</code>	<code>not null</code>	Airport coordinates (longitude and latitude)
<code>timezone</code>	<code>text</code>	<code>not null</code>	Airport time zone

View definition:

```

SELECT ml.airport_code,
       ml.airport_name ->> lang() AS airport_name,
       ml.city ->> lang() AS city,
       ml.coordinates,
       ml.timezone
FROM airports_data ml;

```

#### K.4.5. Table `bookings.airports_data`

This is the base table for the `airports` view. This table contains translations of `airport_name` and `city` values to different languages, in the JSONB format. In most cases, this table is not supposed to be used directly.

Column	Type	Modifiers	Description
<code>airport_code</code>	<code>char(3)</code>	<code>not null</code>	Airport code
<code>airport_name</code>	<code>jsonb</code>	<code>not null</code>	Airport name
<code>city</code>	<code>jsonb</code>	<code>not null</code>	City
<code>coordinates</code>	<code>point</code>	<code>not null</code>	Airport coordinates (longitude and latitude)
<code>timezone</code>	<code>text</code>	<code>not null</code>	Airport time zone

Indexes:

```
PRIMARY KEY, btree (airport_code)
```

Referenced by:

```

TABLE "flights" FOREIGN KEY (arrival_airport)
REFERENCES airports_data(airport_code)
TABLE "flights" FOREIGN KEY (departure_airport)
REFERENCES airports_data(airport_code)

```

### K.4.6. Table `bookings.boarding_passes`

At the time of check-in, which opens twenty-four hours before the scheduled departure, the passenger is issued a boarding pass. Like the flight segment, the boarding pass is identified by the ticket number and the flight number.

Boarding passes are assigned sequential numbers (`boarding_no`), in the order of check-ins for the flight (this number is unique only within the context of a particular flight). The boarding pass specifies the seat number (`seat_no`).

Column	Type	Modifiers	Description
<code>ticket_no</code>	<code>char(13)</code>	<code>not null</code>	Ticket number
<code>flight_id</code>	<code>integer</code>	<code>not null</code>	Flight ID
<code>boarding_no</code>	<code>integer</code>	<code>not null</code>	Boarding pass number
<code>seat_no</code>	<code>varchar(4)</code>	<code>not null</code>	Seat number

Indexes:

```
PRIMARY KEY, btree (ticket_no, flight_id)
UNIQUE CONSTRAINT, btree (flight_id, boarding_no)
UNIQUE CONSTRAINT, btree (flight_id, seat_no)
```

Foreign-key constraints:

```
FOREIGN KEY (ticket_no, flight_id)
REFERENCES ticket_flights(ticket_no, flight_id)
```

### K.4.7. Table `bookings.bookings`

Passengers book tickets for themselves, and, possibly, for several other passengers, in advance (`book_date`, not earlier than one month before the flight). The booking is identified by its number (`book_ref`, a six-position combination of letters and digits).

The `total_amount` field stores the total cost of all tickets included into the booking, for all passengers.

Column	Type	Modifiers	Description
<code>book_ref</code>	<code>char(6)</code>	<code>not null</code>	Booking number
<code>book_date</code>	<code>timestampz</code>	<code>not null</code>	Booking date
<code>total_amount</code>	<code>numeric(10,2)</code>	<code>not null</code>	Total booking cost

Indexes:

```
PRIMARY KEY, btree (book_ref)
```

Referenced by:

```
TABLE "tickets" FOREIGN KEY (book_ref) REFERENCES bookings(book_ref)
```

### K.4.8. Table `bookings.flights`

The natural key of the `bookings.flights` table consists of two fields — `flight_no` and `scheduled_departure`. To make foreign keys for this table more compact, a surrogate key is used as the primary key (`flight_id`).

A flight always connects two points — the airport of departure (`departure_airport`) and arrival (`arrival_airport`). There is no such entity as a “connecting flight”: if there are no non-stop flights from one airport to another, the ticket simply includes several required flight segments.

Each flight has a scheduled date and time of departure (`scheduled_departure`) and arrival (`scheduled_arrival`). The actual departure time (`actual_departure`) and arrival time (`actual_arrival`) can differ: the difference is usually not very big, but sometimes can be up to several hours if the flight is delayed.

**Flight status** (`status`) can take one of the following values:

Scheduled

The flight is available for booking. It happens one month before the planned departure date; before that time, there is no entry for this flight in the database.

On Time

The flight is open for check-in (in twenty-four hours before the scheduled departure) and is not delayed.

Delayed

The flight is open for check-in (in twenty-four hours before the scheduled departure) but is delayed.

Departed

The aircraft has already departed and is airborne.

Arrived

The aircraft has reached the point of destination.

Cancelled

The flight is canceled.

Column	Type	Modifiers	Description
<code>flight_id</code>	<code>serial</code>	<code>not null</code>	Flight ID
<code>flight_no</code>	<code>char(6)</code>	<code>not null</code>	Flight number
<code>scheduled_departure</code>	<code>timestampz</code>	<code>not null</code>	Scheduled departure time
<code>scheduled_arrival</code>	<code>timestampz</code>	<code>not null</code>	Scheduled arrival time
<code>departure_airport</code>	<code>char(3)</code>	<code>not null</code>	Airport of departure
<code>arrival_airport</code>	<code>char(3)</code>	<code>not null</code>	Airport of arrival
<code>status</code>	<code>varchar(20)</code>	<code>not null</code>	Flight status
<code>aircraft_code</code>	<code>char(3)</code>	<code>not null</code>	Aircraft code, IATA
<code>actual_departure</code>	<code>timestampz</code>		Actual departure time
<code>actual_arrival</code>	<code>timestampz</code>		Actual arrival time

Indexes:

```
PRIMARY KEY, btree (flight_id)
UNIQUE CONSTRAINT, btree (flight_no, scheduled_departure)
```

Check constraints:

```
CHECK (scheduled_arrival > scheduled_departure)
CHECK ((actual_arrival IS NULL)
OR ((actual_departure IS NOT NULL AND actual_arrival IS NOT NULL)
AND (actual_arrival > actual_departure)))
CHECK (status IN ('On Time', 'Delayed', 'Departed',
'Arrived', 'Scheduled', 'Cancelled'))
```

Foreign-key constraints:

```
FOREIGN KEY (aircraft_code)
REFERENCES aircrafts(aircraft_code)
FOREIGN KEY (arrival_airport)
REFERENCES airports(airport_code)
FOREIGN KEY (departure_airport)
REFERENCES airports(airport_code)
```

Referenced by:

```
TABLE "ticket_flights" FOREIGN KEY (flight_id)
REFERENCES flights(flight_id)
```

### K.4.9. Table bookings.seats

Seats define the cabin configuration of each aircraft model. Each seat is defined by its number (`seat_no`) and has an assigned travel class (`fare_conditions`): Economy, Comfort or Business.

Column	Type	Modifiers	Description
<code>aircraft_code</code>	<code>char(3)</code>	<code>not null</code>	Aircraft code, IATA
<code>seat_no</code>	<code>varchar(4)</code>	<code>not null</code>	Seat number
<code>fare_conditions</code>	<code>varchar(10)</code>	<code>not null</code>	Travel class

Indexes:

```
PRIMARY KEY, btree (aircraft_code, seat_no)
```

Check constraints:

```
CHECK (fare_conditions IN ('Economy', 'Comfort', 'Business'))
```

Foreign-key constraints:

```
FOREIGN KEY (aircraft_code)
REFERENCES aircrafts(aircraft_code) ON DELETE CASCADE
```

### K.4.10. Table bookings.ticket\_flights

A flight segment connects a ticket with a flight and is identified by their numbers.

Each flight has its cost (`amount`) and travel class (`fare_conditions`).

Column	Type	Modifiers	Description
<code>ticket_no</code>	<code>char(13)</code>	<code>not null</code>	Ticket number
<code>flight_id</code>	<code>integer</code>	<code>not null</code>	Flight ID
<code>fare_conditions</code>	<code>varchar(10)</code>	<code>not null</code>	Travel class
<code>amount</code>	<code>numeric(10,2)</code>	<code>not null</code>	Travel cost

Indexes:

```
PRIMARY KEY, btree (ticket_no, flight_id)
```

Check constraints:

```
CHECK (amount >= 0)
CHECK (fare_conditions IN ('Economy', 'Comfort', 'Business'))
```

Foreign-key constraints:

```
FOREIGN KEY (flight_id) REFERENCES flights(flight_id)
FOREIGN KEY (ticket_no) REFERENCES tickets(ticket_no)
```

Referenced by:

```
TABLE "boarding_passes" FOREIGN KEY (ticket_no, flight_id)
REFERENCES ticket_flights(ticket_no, flight_id)
```

### K.4.11. Table bookings.tickets

A ticket has a unique number (`ticket_no`) that consists of 13 digits.

The ticket includes a passenger ID (`passenger_id`) — the identity document number, — their first and last names (`passenger_name`), and contact information (`contact_data`).

Neither the passenger ID, nor the name is permanent (for example, one can change the last name or passport), so it is impossible to uniquely identify all tickets of a particular passenger.

Column	Type	Modifiers	Description
<code>ticket_no</code>	<code>char(13)</code>	<code>not null</code>	Ticket number
<code>book_ref</code>	<code>char(6)</code>	<code>not null</code>	Booking number
<code>passenger_id</code>	<code>varchar(20)</code>	<code>not null</code>	Passenger ID
<code>passenger_name</code>	<code>text</code>	<code>not null</code>	Passenger name

```

contact_data | jsonb | | Passenger contact information
Indexes:
PRIMARY KEY, btree (ticket_no)
Foreign-key constraints:
FOREIGN KEY (book_ref) REFERENCES bookings(book_ref)
Referenced by:
TABLE "ticket_flights" FOREIGN KEY (ticket_no) REFERENCES tickets(ticket_no)

```

### K.4.12. View bookings.flights\_v

There is a `flights_v` view over the `flights` table that provides additional information:

- Details about the airport of departure — `departure_airport`, `departure_airport_name`, `departure_city`
- Details about the airport of arrival — `arrival_airport`, `arrival_airport_name`, `arrival_city`
- Local departure time — `scheduled_departure_local`, `actual_departure_local`
- Local arrival time — `scheduled_arrival_local`, `actual_arrival_local`
- Flight duration — `scheduled_duration`, `actual_duration`.

Column	Type	Description
<code>flight_id</code>	<code>integer</code>	Flight ID
<code>flight_no</code>	<code>char(6)</code>	Flight number
<code>scheduled_departure</code>	<code>timestamptz</code>	Scheduled departure time
<code>scheduled_departure_local</code>	<code>timestamp</code>	Scheduled departure time, local time at the point of departure
<code>scheduled_arrival</code>	<code>timestamptz</code>	Scheduled arrival time
<code>scheduled_arrival_local</code>	<code>timestamp</code>	Scheduled arrival time, local time at the point of destination
<code>scheduled_duration</code>	<code>interval</code>	Scheduled flight duration
<code>departure_airport</code>	<code>char(3)</code>	Departure airport code
<code>departure_airport_name</code>	<code>text</code>	Departure airport name
<code>departure_city</code>	<code>text</code>	City of departure
<code>arrival_airport</code>	<code>char(3)</code>	Arrival airport code
<code>arrival_airport_name</code>	<code>text</code>	Arrival airport name
<code>arrival_city</code>	<code>text</code>	City of arrival
<code>status</code>	<code>varchar(20)</code>	Flight status
<code>aircraft_code</code>	<code>char(3)</code>	Aircraft code, IATA
<code>actual_departure</code>	<code>timestamptz</code>	Actual departure time
<code>actual_departure_local</code>	<code>timestamp</code>	Actual departure time, local time at the point of departure
<code>actual_arrival</code>	<code>timestamptz</code>	Actual arrival time
<code>actual_arrival_local</code>	<code>timestamp</code>	Actual arrival time, local time at the point of destination
<code>actual_duration</code>	<code>interval</code>	Actual flight duration

### K.4.13. View bookings.routes

The `bookings.flights` table contains some redundancies, which you can use to single out route information (flight number, airports of departure and destination) that does not depend on the exact flight dates.

Such information is shown in the `routes` view.

Column	Type	Description
--------	------	-------------

<code>flight_no</code>	char(6)	Flight number
<code>departure_airport</code>	char(3)	Departure airport code
<code>departure_airport_name</code>	text	Departure airport name
<code>departure_city</code>	text	City of departure
<code>arrival_airport</code>	char(3)	Arrival airport code
<code>arrival_airport_name</code>	text	Arrival airport name
<code>arrival_city</code>	text	City of arrival
<code>aircraft_code</code>	char(3)	Aircraft code, IATA
<code>duration</code>	interval	Flight duration
<code>days_of_week</code>	integer[]	Days of the week on which flights are performed

#### K.4.14. Function `bookings.now`

The demo database contains “snapshots” of data — similar to a backup copy of a real system captured at some point in time. For example, if a flight has the `Departed` status, it means that the aircraft had already departed and was airborne at the time of the backup copy.

The “snapshot” time is saved in the `bookings.now()` function. You can use this function in demo queries for cases where you would use the `now()` function in a real database.

In addition, the return value of this function determines the version of the demo database. The latest version available is of August 15, 2017.

#### K.4.15. Function `bookings.lang`

Some fields in the demo database are available in English and Russian. Translations to other languages are not provided, but are easy to add. The `bookings.lang` returns the value of the `bookings.lang` parameter, that is, the language in which these fields will be displayed.

This function is used in the `aircrafts` and `airports` views and is not intended to be used directly in queries.

### K.5. Usage

#### K.5.1. Schema `bookings`

The `bookings` schema contains all objects of the demo database. When you connect to the database, `search_path` configuration parameter is automatically set to `bookings, public`, so you do not need to specify the schema name explicitly.

However, for the `bookings.now` function, you always have to specify the schema to distinguish this function from the standard `now` function.

#### K.5.2. Translations

By default, values of several translatable fields are shown in Russian. These are `airport_name` and `city` of the `airports` view, as well as `model` of the `aircrafts` view.

You can choose to display these fields in another language (although only the English translation is provided in the demo database). To switch to English, set the `bookings.lang` parameter to `en`. It may be convenient to choose the language at the database level:

```
ALTER DATABASE demo SET bookings.lang = en;
```

You have to reconnect to the database for this command to take effect. For other methods of settings configuration parameters, see [Section 18.1](#).

In the examples below, the English language is selected for translatable fields.

### K.5.3. Sample Queries

To better understand the contents of the demo database, let's take a look at the results of several simple queries.

The results displayed below were received on a small database version (demo-small) of August 15, 2017. If the same queries return different data on your system, check your demo database version (using the `bookings.now` function). Some minor deviations may be caused by the difference between your local time and Moscow time, or your locale settings.

All flights are operated by several types of aircraft:

```
SELECT * FROM aircrafts;
```

aircraft_code	model	range
773	Boeing 777-300	11100
763	Boeing 767-300	7900
SU9	Sukhoi SuperJet-100	3000
320	Airbus A320-200	5700
321	Airbus A321-200	5600
319	Airbus A319-100	6700
733	Boeing 737-300	4200
CN1	Cessna 208 Caravan	1200
CR2	Bombardier CRJ-200	2700

(9 rows)

For each aircraft type, a separate list of seats is supported. For example, in a small Cessna 208 Caravan, one can select the following seats:

```
SELECT  a.aircraft_code,
        a.model,
        s.seat_no,
        s.fare_conditions
FROM    aircrafts a
        JOIN seats s ON a.aircraft_code = s.aircraft_code
WHERE   a.model = 'Cessna 208 Caravan'
ORDER BY s.seat_no;
```

aircraft_code	model	seat_no	fare_conditions
CN1	Cessna 208 Caravan	1A	Economy
CN1	Cessna 208 Caravan	1B	Economy
CN1	Cessna 208 Caravan	2A	Economy
CN1	Cessna 208 Caravan	2B	Economy
CN1	Cessna 208 Caravan	3A	Economy
CN1	Cessna 208 Caravan	3B	Economy
CN1	Cessna 208 Caravan	4A	Economy
CN1	Cessna 208 Caravan	4B	Economy
CN1	Cessna 208 Caravan	5A	Economy
CN1	Cessna 208 Caravan	5B	Economy
CN1	Cessna 208 Caravan	6A	Economy
CN1	Cessna 208 Caravan	6B	Economy

(12 rows)

Bigger aircraft have more seats of various travel classes:

```
SELECT  s2.aircraft_code,
```

```

string_agg (s2.fare_conditions || '(' || s2.num::text || ')',
            ', ') as fare_conditions
FROM      (
    SELECT  s.aircraft_code, s.fare_conditions, count(*) as num
    FROM    seats s
    GROUP BY s.aircraft_code, s.fare_conditions
    ORDER BY s.aircraft_code, s.fare_conditions
) s2
GROUP BY s2.aircraft_code
ORDER BY s2.aircraft_code;

```

aircraft_code	fare_conditions
319	Business (20), Economy (96)
320	Business (20), Economy (120)
321	Business (28), Economy (142)
733	Business (12), Economy (118)
763	Business (30), Economy (192)
773	Business (30), Comfort (48), Economy (324)
CN1	Economy (12)
CR2	Economy (50)
SU9	Business (12), Economy (85)

(9 rows)

The demo database contains the list of airports of almost all major Russian cities. Most cities have only one airport. The exceptions are:

```

SELECT  a.airport_code as code,
        a.airport_name,
        a.city,
        a.coordinates
FROM    airports a
WHERE   a.city IN (
        SELECT  aa.city
        FROM    airports aa
        GROUP BY aa.city
        HAVING  COUNT(*) > 1
    )
ORDER BY a.city, a.airport_code;

```

code	airport_name	city	coordinates
DME	Domodedovo International Airport	Moscow	(37.9062995910645, 55.4087982177734)
SVO	Sheremetyevo International Airport	Moscow	(37.4146, 55.972599)
VKO	Vnukovo International Airport	Moscow	(37.2615013123, 55.5914993286)
ULV	Ulyanovsk Baratayevka Airport	Ulyanovsk	(48.2266998291, 54.2682991028)
ULY	Ulyanovsk East Airport	Ulyanovsk	(48.8027000427246, 54.4010009765625)

(5 rows)

To learn about your flying options from one point to another, it is convenient to use the `routes` materialized view that aggregates information on all flights. For example, here are the destinations where you can get from Volgograd on specific days of the week, with flight duration:

## Demo Database "Airlines"

```
SELECT r.arrival_city as city,
       r.arrival_airport as code,
       r.arrival_airport_name as airport_name,
       r.days_of_week,
       r.duration
FROM   routes r
WHERE  r.departure_city = ' Volgograd';
```

city	code	airport_name	days_of_week	duration
Moscow	SVO	Sheremetyevo International Airport	{1,2,3,4,5,6,7}	01:15:00
Chelyabinsk	CEK	Chelyabinsk Balandino Airport	{1,2,3,4,5,6,7}	01:50:00
Rostov	ROV	Rostov-on-Don Airport	{1,2,3,4,5,6,7}	00:30:00
Moscow	VKO	Vnukovo International Airport	{1,2,3,4,5,6,7}	01:10:00
Cheboksary	CSY	Cheboksary Airport	{1,2,3,4,5,6,7}	02:45:00
Tomsk	TOF	Bogashevo Airport	{1}	03:50:00

(6 rows)

The database was formed at the moment returned by the `bookings.now()` function:

```
SELECT bookings.now() as now;
```

```
      now
-----
2017-08-15 18:00:00+03
```

In relation to this moment, all flights are classified as past and future flights:

```
SELECT  status,
        count(*) as count,
        min(scheduled_departure) as min_scheduled_departure,
        max(scheduled_departure) as max_scheduled_departure
FROM    flights
GROUP BY status
ORDER BY min_scheduled_departure;
```

status	count	min_scheduled_departure	max_scheduled_departure
Arrived	16707	2017-07-16 01:50:00+03	2017-08-15 17:25:00+03
Cancelled	414	2017-07-19 11:35:00+03	2017-09-14 20:55:00+03
Departed	58	2017-08-15 09:55:00+03	2017-08-15 17:50:00+03
Delayed	41	2017-08-15 15:15:00+03	2017-08-16 17:25:00+03
On Time	518	2017-08-15 17:55:00+03	2017-08-16 18:00:00+03
Scheduled	15383	2017-08-16 18:05:00+03	2017-09-14 20:40:00+03

(6 rows)

Let's find the next flight from Yekaterinburg to Moscow. The `flight` table is not very convenient for such queries, as it does not include information on the cities of departure and arrival. That is why we will use the `flights_v` view:

```
\x
SELECT  f.*
FROM    flights_v f
WHERE   f.departure_city = 'Yekaterinburg'
AND     f.arrival_city = 'Moscow'
```

```
AND      f.scheduled_departure > bookings.now()
ORDER BY f.scheduled_departure
LIMIT   1;
```

```
-[ RECORD 1 ]-----+-----
flight_id      | 10927
flight_no      | PG0226
scheduled_departure | 2017-08-16 08:10:00+03
scheduled_departure_local | 2017-08-16 10:10:00
scheduled_arrival | 2017-08-16 09:55:00+03
scheduled_arrival_local | 2017-08-16 09:55:00
scheduled_duration | 01:45:00
departure_airport | SVX
departure_airport_name | Koltsovo Airport
departure_city | Yekaterinburg
arrival_airport | SVO
arrival_airport_name | Sheremetyevo International Airport
arrival_city | Moscow
status | On Time
aircraft_code | 773
actual_departure |
actual_departure_local |
actual_arrival |
actual_arrival_local |
actual_duration |
```

Note that the `flights_v` view shows both Moscow time and local time at the airports of departure and arrival.

## K.5.4. Bookings

Each booking can include several tickets, one for each passenger. The ticket, in its turn, can include several flight segments. The complete information about the booking is stored in three tables: `bookings`, `tickets`, and `ticket_flights`.

Let's find several most expensive bookings:

```
SELECT *
FROM   bookings
ORDER BY total_amount desc
LIMIT  10;
```

book_ref	book_date	total_amount
3B54BB	2017-07-05 17:08:00+03	1204500.00
3AC131	2017-07-31 01:06:00+03	1087100.00
65A6EA	2017-07-03 06:28:00+03	1065600.00
D7E9AA	2017-08-08 05:29:00+03	1062800.00
EF479E	2017-08-02 15:58:00+03	1035100.00
521C53	2017-07-08 09:25:00+03	985500.00
514CA6	2017-07-27 05:07:00+03	955000.00
D70BD9	2017-07-05 12:47:00+03	947500.00
EC7EDA	2017-07-02 16:13:00+03	946800.00
8E4370	2017-07-28 02:04:00+03	945700.00

(10 rows)

Let's take a look at the tickets included into the booking with code 521C53:

```
SELECT ticket_no,
       passenger_id,
       passenger_name
FROM   tickets
WHERE  book_ref = '521C53';
```

ticket_no	passenger_id	passenger_name
0005432661914	8234 547529	IVAN IVANOV
0005432661915	2034 201228	ANTONINA KUZNECOVA

(2 rows)

If we would like to know, which flight segments are included into Antonina Kuznecova's ticket, we can use the following query:

```
SELECT  to_char(f.scheduled_departure, 'DD.MM.YYYY') AS when,
        f.departure_city || ' (' || f.departure_airport || ')' AS departure,
        f.arrival_city || ' (' || f.arrival_airport || ')' AS arrival,
        tf.fare_conditions AS class,
        tf.amount
FROM    ticket_flights tf
        JOIN flights_v f ON tf.flight_id = f.flight_id
WHERE   tf.ticket_no = '0005432661915'
ORDER BY f.scheduled_departure;
```

when	departure	arrival	class	amount
29.07.2017	Moscow (SVO)	Anadyr (DYR)	Business	185300.00
02.08.2017	Anadyr (DYR)	Khabarovsk (KHV)	Business	92200.00
03.08.2017	Khabarovsk (KHV)	Blagoveshchensk (BQS)	Business	18000.00
08.08.2017	Blagoveshchensk (BQS)	Khabarovsk (KHV)	Business	18000.00
12.08.2017	Khabarovsk (KHV)	Anadyr (DYR)	Economy	30700.00
17.08.2017	Anadyr (DYR)	Moscow (SVO)	Business	185300.00

(6 rows)

As we can see, high booking cost is explained by multiple long-haul flights in business class.

Some of the flight segments in this ticket have earlier dates than the `bookings.now()` return value: it means that these flights had already happened. The last flight had not happened yet at the time of the database creation. After the check-in, a boarding pass with the allocated seat number is issued. We can check the exact seats occupied by Antonina (note the outer left join with table `boarding_passes`):

```
SELECT  to_char(f.scheduled_departure, 'DD.MM.YYYY') AS when,
        f.departure_city || ' (' || f.departure_airport || ')' AS departure,
        f.arrival_city || ' (' || f.arrival_airport || ')' AS arrival,
        f.status,
        bp.seat_no
FROM    ticket_flights tf
        JOIN flights_v f ON tf.flight_id = f.flight_id
        LEFT JOIN boarding_passes bp ON tf.flight_id = bp.flight_id
        AND tf.ticket_no = bp.ticket_no
WHERE   tf.ticket_no = '0005432661915'
ORDER BY f.scheduled_departure;
```

when	departure	arrival	status	seat_no
------	-----------	---------	--------	---------

```

29.07.2017 | Moscow (SVO)           | Anadyr (DYR)           | Arrived   | 5C
02.08.2017 | Anadyr (DYR)             | Khabarovsk (KHV)      | Arrived   | 1D
03.08.2017 | Khabarovsk (KHV)        | Blagoveshchensk (BQS) | Arrived   | 2C
08.08.2017 | Blagoveshchensk (BQS)   | Khabarovsk (KHV)      | Arrived   | 2D
12.08.2017 | Khabarovsk (KHV)        | Anadyr (DYR)           | Arrived   | 20B
17.08.2017 | Anadyr (DYR)            | Moscow (SVO)           | Scheduled |
(6 rows)

```

## K.5.5. New Booking

Let's try to send Aleksandr Radishchev from Saint Petersburg to Moscow — the route that made him famous. Naturally, he will travel for free and in business class. We have already found a flight for tomorrow, and a return flight a week later.

```

BEGIN;

INSERT INTO bookings (book_ref, book_date, total_amount)
VALUES      ('_QWE12', bookings.now(), 0);

INSERT INTO tickets (ticket_no, book_ref, passenger_id, passenger_name)
VALUES      ('_0000000000001', '_QWE12', '1749 051790', 'ALEKSANDR RADISHCHEV');

INSERT INTO ticket_flights (ticket_no, flight_id, fare_conditions, amount)
VALUES      ('_0000000000001', 8525, 'Business', 0),
            ('_0000000000001', 4967, 'Business', 0);

COMMIT;

```

To avoid conflicts with the range of values present in the database, identifiers are started with an underscore.

We will check in Aleksandr for tomorrow's flight right away:

```

INSERT INTO boarding_passes (ticket_no, flight_id, boarding_no, seat_no)
VALUES      ('_0000000000001', 8525, 1, '1A');

```

Now let's check the booking information:

```

SELECT      b.book_ref,
            t.ticket_no,
            t.passenger_id,
            t.passenger_name,
            tf.fare_conditions,
            tf.amount,
            f.scheduled_departure_local,
            f.scheduled_arrival_local,
            f.departure_city || ' (' || f.departure_airport || ')' AS departure,
            f.arrival_city || ' (' || f.arrival_airport || ')' AS arrival,
            f.status,
            bp.seat_no
FROM        bookings b
            JOIN tickets t ON b.book_ref = t.book_ref
            JOIN ticket_flights tf ON tf.ticket_no = t.ticket_no
            JOIN flights_v f ON tf.flight_id = f.flight_id
            LEFT JOIN boarding_passes bp ON tf.flight_id = bp.flight_id
            AND tf.ticket_no = bp.ticket_no

WHERE      b.book_ref = '_QWE12'

```

## Demo Database "Airlines"

---

```
ORDER BY t.ticket_no, f.scheduled_departure;
```

```
-[ RECORD 1 ]-----+-----  
book_ref          | _QWE12  
ticket_no        | _0000000000001  
passenger_id     | 1749 051790  
passenger_name   | ALEKSANDR RADISHCHEV  
fare_conditions  | Business  
amount          | 0.00  
scheduled_departure_local | 2017-08-16 09:45:00  
scheduled_arrival_local  | 2017-08-16 10:35:00  
departure        | St. Petersburg (LED)  
arrival          | Moscow (SVO)  
status           | On Time  
seat_no          | 1A  
-[ RECORD 2 ]-----+-----  
book_ref          | _QWE12  
ticket_no        | _0000000000001  
passenger_id     | 1749 051790  
passenger_name   | ALEKSANDR RADISHCHEV  
fare_conditions  | Business  
amount          | 0.00  
scheduled_departure_local | 2017-08-23 10:20:00  
scheduled_arrival_local  | 2017-08-23 11:10:00  
departure        | Moscow (SVO)  
arrival          | St. Petersburg (LED)  
status           | Scheduled  
seat_no          |
```

We hope that these simple examples helped you get an idea of this demo database.

---

# Appendix M. Glossary

This is a list of terms and their meaning in the context of PostgreSQL and relational database systems in general.

ACID		<i>Atomicity, Consistency, Isolation, and Durability</i> . This set of properties of database transactions is intended to guarantee validity in concurrent operation and even in event of errors, power failures, etc.
Aggregate (routine)	function	A <i>function</i> that combines ( <i>aggregates</i> ) multiple input values, for example by counting, averaging or adding, yielding a single output value.  For more information, see <a href="#">Section 9.21</a> .  See Also <a href="#">Window function (routine)</a> .
Analytic function		See <a href="#">Window function (routine)</a> .
Analyze (operation)		The process of collecting statistics from data in <i>tables</i> and other <i>relations</i> to help the <i>query planner</i> to make decisions about how to execute <i>queries</i> .  (Don't confuse this term with the <code>ANALYZE</code> option to the <code>EXPLAIN</code> command.)  For more information, see <a href="#">ANALYZE</a> .
Atomic		In reference to a <i>datum</i> : the fact that its value cannot be broken down into smaller components.  In reference to a <i>database transaction</i> : see <i>atomicity</i> .
Atomicity		The property of a <i>transaction</i> that either all its operations complete as a single unit or none do. In addition, if a system failure occurs during the execution of a transaction, no partial results are visible after recovery. This is one of the ACID properties.
Attribute		An element with a certain name and data type found within a <i>tuple</i> .
Autovacuum (process)		A set of background processes that routinely perform <i>vacuum</i> and <i>analyze</i> operations.  For more information, see <a href="#">Section 23.1.6</a> .
Backend (process)		Process of an <i>instance</i> which acts on behalf of a <i>client session</i> and handles its requests.  (Don't confuse this term with the similar terms <i>Background Worker</i> or <i>Background Writer</i> ).
Background (process)	worker	Process within an <i>instance</i> , which runs system- or user-supplied code. Serves as infrastructure for several features in PostgreSQL, such as <i>logical replication</i> and <i>parallel queries</i> . In addition, <i>Extensions</i> can add custom background worker processes.  For more information, see <a href="#">Chapter 45</a> .
Background (process)	writer	A process that writes dirty <i>data pages</i> from <i>shared memory</i> to the file system. It wakes up periodically, but works only for a short period in order to distribute its expensive I/O activity over time to avoid generating larger I/O peaks which could block other processes.  For more information, see <a href="#">Section 18.4.5</a> .

Bloat	Space in data pages which does not contain current row versions, such as unused (free) space or outdated row versions.
Cast	A conversion of a <i>datum</i> from its current data type to another data type.  For more information, see <a href="#">CREATE CAST</a> .
Catalog	The SQL standard uses this term to indicate what is called a <i>database</i> in PostgreSQL's terminology.  (Don't confuse this term with <i>system catalog</i> ).  For more information, see <a href="#">Section 21.1</a> .
Check constraint	A type of <i>constraint</i> defined on a <i>relation</i> which restricts the values allowed in one or more <i>attributes</i> . The check constraint can make reference to any attribute of the same row in the relation, but cannot reference other rows of the same relation or other relations.  For more information, see <a href="#">Section 5.4</a> .
Checkpoint	A point in the <i>WAL</i> sequence at which it is guaranteed that the heap and index data files have been updated with all information from <i>shared memory</i> modified before that checkpoint; a <i>checkpoint record</i> is written and flushed to WAL to mark that point.  A checkpoint is also the act of carrying out all the actions that are necessary to reach a checkpoint as defined above. This process is initiated when predefined conditions are met, such as a specified amount of time has passed, or a certain volume of records has been written; or it can be invoked by the user with the command <code>CHECKPOINT</code> .  For more information, see <a href="#">Section 28.4</a> .
Checkpointer (process)	A specialized process responsible for executing checkpoints.
Class (archaic)	See <a href="#">Relation</a> .
Client (process)	Any process, possibly remote, that establishes a <i>session</i> by <i>connecting</i> to an <i>instance</i> to interact with a <i>database</i> .
Column	An <i>attribute</i> found in a <i>table</i> or <i>view</i> .
Commit	The act of finalizing a <i>transaction</i> within the <i>database</i> , which makes it visible to other transactions and assures its <i>durability</i> .  For more information, see <a href="#">COMMIT</a> .
Concurrency	The concept that multiple independent operations happen within the <i>database</i> at the same time. In PostgreSQL, concurrency is controlled by the <i>multiversion concurrency control</i> mechanism.
Connection	An established line of communication between a client process and a <i>backend</i> process, usually over a network, supporting a <i>session</i> . This term is sometimes used as a synonym for session.  For more information, see <a href="#">Section 18.3</a> .
Consistency	The property that the data in the <i>database</i> is always in compliance with <i>integrity constraints</i> . Transactions may be allowed to violate some of the constraints transiently before it commits, but if such violations are not

	resolved by the time it commits, such a transaction is automatically <i>rolled back</i> . This is one of the ACID properties.
Constraint	<p>A restriction on the values of data allowed within a <i>table</i>, or in attributes of a <i>domain</i>.</p> <p>For more information, see <a href="#">Section 5.4</a>.</p>
Data area	See <a href="#">Data directory</a> .
Database	<p>A named collection of <i>local SQL objects</i>.</p> <p>For more information, see <a href="#">Section 21.1</a>.</p>
Database cluster	<p>A collection of databases and global SQL objects, and their common static and dynamic metadata. Sometimes referred to as a <i>cluster</i>.</p> <p>In PostgreSQL, the term <i>cluster</i> is also sometimes used to refer to an instance. (Don't confuse this term with the SQL command <code>CLUSTER</code>.)</p>
Database server	See <a href="#">Instance</a> .
Data directory	<p>The base directory on the file system of a <i>server</i> that contains all data files and subdirectories associated with a <i>database cluster</i> (with the exception of <i>tablespaces</i>, and optionally <i>WAL</i>). The environment variable <code>PGDATA</code> is commonly used to refer to the data directory.</p> <p>A <i>cluster's</i> storage space comprises the data directory plus any additional tablespaces.</p> <p>For more information, see <a href="#">Section 65.1</a>.</p>
Data page	The basic structure used to store relation data. All pages are of the same size. Data pages are typically stored on disk, each in a specific file, and can be read to <i>shared buffers</i> where they can be modified, becoming <i>dirty</i> . They become clean when written to disk. New pages, which initially exist in memory only, are also dirty until written.
Datum	The internal representation of one value of an SQL data type.
Delete	<p>An SQL command which removes <i>rows</i> from a given <i>table</i> or <i>relation</i>.</p> <p>For more information, see <a href="#">DELETE</a>.</p>
Durability	The assurance that once a <i>transaction</i> has been <i>committed</i> , the changes remain even after a system failure or crash. This is one of the ACID properties.
Epoch	See <a href="#">Transaction ID</a> .
Extension	<p>A software add-on package that can be installed on an <i>instance</i> to get extra features.</p> <p>For more information, see <a href="#">Section 35.17</a>.</p>
File segment	<p>A physical file which stores data for a given <i>relation</i>. File segments are limited in size by a configuration value (typically 1 gigabyte), so if a relation exceeds that size, it is split into multiple segments.</p> <p>For more information, see <a href="#">Section 65.1</a>.</p> <p>(Don't confuse this term with the similar term <i>WAL segment</i>).</p>

Foreign data wrapper	<p>A means of representing data that is not contained in the local <i>database</i> so that it appears as if were in local <i>table(s)</i>. With a foreign data wrapper it is possible to define a <i>foreign server</i> and <i>foreign tables</i>.</p> <p>For more information, see <a href="#">CREATE FOREIGN DATA WRAPPER</a>.</p>
Foreign key	<p>A type of <i>constraint</i> defined on one or more <i>columns</i> in a <i>table</i> which requires the value(s) in those <i>columns</i> to identify zero or one <i>row</i> in another (or, infrequently, the same) <i>table</i>.</p>
Foreign server	<p>A named collection of <i>foreign tables</i> which all use the same <i>foreign data wrapper</i> and have other configuration values in common.</p> <p>For more information, see <a href="#">CREATE SERVER</a>.</p>
Foreign table (relation)	<p>A <i>relation</i> which appears to have <i>rows</i> and <i>columns</i> similar to a regular <i>table</i>, but will forward requests for data through its <i>foreign data wrapper</i>, which will return <i>result sets</i> structured according to the definition of the <i>foreign table</i>.</p> <p>For more information, see <a href="#">CREATE FOREIGN TABLE</a>.</p>
Fork	<p>Each of the separate segmented file sets in which a relation is stored. The <i>main fork</i> is where the actual data resides. There also exist two secondary forks for metadata: the <i>free space map</i> and the <i>visibility map</i>. <i>Unlogged relations</i> also have an <i>init fork</i>.</p>
Free space map (fork)	<p>A storage structure that keeps metadata about each data page of a table's main fork. The free space map entry for each page stores the amount of free space that's available for future tuples, and is structured to be efficiently searched for available space for a new tuple of a given size.</p> <p>For more information, see <a href="#">Section 65.3</a>.</p>
Function (routine)	<p>A type of routine that receives zero or more arguments, returns zero or more output values, and is constrained to run within one transaction. Functions are invoked as part of a query, for example via <code>SELECT</code>. Certain functions can return <i>sets</i>; those are called <i>set-returning functions</i>.</p> <p>Functions can also be used for <i>triggers</i> to invoke.</p> <p>For more information, see <a href="#">CREATE FUNCTION</a>.</p>
Grant	<p>An SQL command that is used to allow a <i>user</i> or <i>role</i> to access specific objects within the <i>database</i>.</p> <p>For more information, see <a href="#">GRANT</a>.</p>
Heap	<p>Contains the values of <i>row</i> attributes (i.e., the data) for a <i>relation</i>. The heap is realized within one or more <i>file segments</i> in the relation's <i>main fork</i>.</p>
Host	<p>A computer that communicates with other computers over a network. This is sometimes used as a synonym for <i>server</i>. It is also used to refer to a computer where <i>client processes</i> run.</p>
Index (relation)	<p>A <i>relation</i> that contains data derived from a <i>table</i> or <i>materialized view</i>. Its internal structure supports fast retrieval of and access to the original data.</p> <p>For more information, see <a href="#">CREATE INDEX</a>.</p>
Insert	<p>An SQL command used to add new data into a <i>table</i>.</p>

		For more information, see <a href="#">INSERT</a> .
Instance		<p>A group of backend and auxiliary processes that communicate using a common shared memory area. One <i>postmaster process</i> manages the instance; one instance manages exactly one <i>database cluster</i> with all its databases. Many instances can run on the same <i>server</i> as long as their TCP ports do not conflict.</p> <p>The instance handles all key features of a DBMS: read and write access to files and shared memory, assurance of the ACID properties, <i>connections</i> to <i>client processes</i>, privilege verification, crash recovery, replication, etc.</p>
Isolation		<p>The property that the effects of a transaction are not visible to <i>concurrent transactions</i> before it commits. This is one of the ACID properties.</p> <p>For more information, see <a href="#">Section 13.2</a>.</p>
Join		An operation and SQL keyword used in <i>queries</i> for combining data from multiple <i>relations</i> .
Key		A means of identifying a <i>row</i> within a <i>table</i> or other <i>relation</i> by values contained within one or more <i>attributes</i> in that relation.
Lock		A mechanism that allows a process to limit or prevent simultaneous access to a resource.
Log file		<p>Log files contain human-readable text lines about events. Examples include login failures, long-running queries, etc.</p> <p>For more information, see <a href="#">Section 23.3</a>.</p>
Logged		A <i>table</i> is considered <i>logged</i> if changes to it are sent to the <i>WAL</i> . By default, all regular tables are logged. A table can be specified as <i>unlogged</i> either at creation time or via the <code>ALTER TABLE</code> command.
Logger (process)		<p>If activated, the process writes information about database events into the current <i>log file</i>. When reaching certain time- or volume-dependent criteria, a new log file is created. Also called <i>syslogger</i>.</p> <p>For more information, see <a href="#">Section 18.8</a>.</p>
Log record		Archaic term for a <i>WAL record</i> .
Master (server)		See <a href="#">Primary (server)</a> .
Materialized		<p>The property that some information has been pre-computed and stored for later use, rather than computing it on-the-fly.</p> <p>This term is used in <i>materialized view</i>, to mean that the data derived from the view's query is stored on disk separately from the sources of that data.</p> <p>This term is also used to refer to some multi-step queries to mean that the data resulting from executing a given step is stored in memory (with the possibility of spilling to disk), so that it can be read multiple times by another step.</p>
Materialized (relation)	view	A <i>relation</i> that is defined by a <code>SELECT</code> statement (just like a <i>view</i> ), but stores data in the same way that a <i>table</i> does. It cannot be modified via <code>INSERT</code> , <code>UPDATE</code> , or <code>DELETE</code> operations.

		For more information, see <a href="#">CREATE MATERIALIZED VIEW</a> .
Multi-version concurrency control (MVCC)		A mechanism designed to allow several <i>transactions</i> to be reading and writing the same rows without one process causing other processes to stall. In PostgreSQL, MVCC is implemented by creating copies ( <i>versions</i> ) of <i>tuples</i> as they are modified; after transactions that can see the old versions terminate, those old versions need to be removed.
Null		A concept of non-existence that is a central tenet of relational database theory. It represents the absence of a definite value.
Optimizer		See <a href="#">Query planner</a> .
Parallel query		The ability to handle parts of executing a <i>query</i> to take advantage of parallel processes on servers with multiple CPUs.
Partition		One of several disjoint (not overlapping) subsets of a larger set.  In reference to a <i>partitioned table</i> : One of the tables that each contain part of the data of the partitioned table, which is said to be the <i>parent</i> . The partition is itself a table, so it can also be queried directly; at the same time, a partition can sometimes be a partitioned table, allowing hierarchies to be created.  In reference to a <i>window function</i> in a <i>query</i> , a partition is a user-defined criterion that identifies which neighboring <i>rows</i> of the <i>query's result set</i> can be considered by the function.
Partitioned (relation)	table	A <i>relation</i> that is in semantic terms the same as a <i>table</i> , but whose storage is distributed across several <i>partitions</i> .
Postmaster (process)		The very first process of an <i>instance</i> . It starts and manages the other auxiliary processes and creates <i>backend processes</i> on demand.  For more information, see <a href="#">Section 17.3</a> .
Primary key		A special case of a <i>unique constraint</i> defined on a <i>table</i> or other <i>relation</i> that also guarantees that all of the <i>attributes</i> within the <i>primary key</i> do not have <i>null</i> values. As the name implies, there can be only one primary key per table, though it is possible to have multiple unique constraints that also have no null-capable attributes.
Primary (server)		When two or more <i>databases</i> are linked via <i>replication</i> , the <i>server</i> that is considered the authoritative source of information is called the <i>primary</i> , also known as a <i>master</i> .
Procedure (routine)		A type of routine. Their distinctive qualities are that they do not return values, and that they are allowed to make transactional statements such as COMMIT and ROLLBACK. They are invoked via the CALL command.  For more information, see <a href="#">CREATE PROCEDURE</a> .
Query		A request sent by a client to a <i>backend</i> , usually to return results or to modify data on the database.
Query planner		The part of PostgreSQL that is devoted to determining ( <i>planning</i> ) the most efficient way to execute <i>queries</i> . Also known as <i>query optimizer</i> , <i>optimizer</i> , or simply <i>planner</i> .
Record		See <a href="#">Tuple</a> .

Recycling	See <a href="#">WAL file</a> .
Referential integrity	A means of restricting data in one <i>relation</i> by a <i>foreign key</i> so that it must have matching data in another <i>relation</i> .
Relation	<p>The generic term for all objects in a <i>database</i> that have a name and a list of <i>attributes</i> defined in a specific order. <i>Tables</i>, <i>sequences</i>, <i>views</i>, <i>foreign tables</i>, <i>materialized views</i>, composite types, and <i>indexes</i> are all relations.</p> <p>More generically, a relation is a set of tuples; for example, the result of a query is also a relation.</p> <p>In PostgreSQL, <i>Class</i> is an archaic synonym for <i>relation</i>.</p>
Replica (server)	A <i>database</i> that is paired with a <i>primary</i> database and is maintaining a copy of some or all of the primary database's data. The foremost reasons for doing this are to allow for greater access to that data, and to maintain availability of the data in the event that the <i>primary</i> becomes unavailable.
Replication	The act of reproducing data on one <i>server</i> onto another server called a <i>replica</i> . This can take the form of <i>physical replication</i> , where all file changes from one server are copied verbatim, or <i>logical replication</i> where a defined subset of data changes are conveyed using a higher-level representation.
Result set	<p>A <i>relation</i> transmitted from a <i>backend process</i> to a <i>client</i> upon the completion of an SQL command, usually a <code>SELECT</code> but it can be an <code>INSERT</code>, <code>UPDATE</code>, or <code>DELETE</code> command if the <code>RETURNING</code> clause is specified.</p> <p>The fact that a result set is a relation means that a query can be used in the definition of another query, becoming a <i>subquery</i>.</p>
Revoke	<p>A command to prevent access to a named set of <i>database</i> objects for a named list of <i>roles</i>.</p> <p>For more information, see <a href="#">REVOKE</a>.</p>
Role	<p>A collection of access privileges to the <i>instance</i>. Roles are themselves a privilege that can be granted to other roles. This is often done for convenience or to ensure completeness when multiple <i>users</i> need the same privileges.</p> <p>For more information, see <a href="#">CREATE ROLE</a>.</p>
Rollback	<p>A command to undo all of the operations performed since the beginning of a <i>transaction</i>.</p> <p>For more information, see <a href="#">ROLLBACK</a>.</p>
Routine	<p>A defined set of instructions stored in the database system that can be invoked for execution. A routine can be written in a variety of programming languages. Routines can be <i>functions</i> (including set-returning functions and <i>trigger functions</i>), <i>aggregate functions</i>, and <i>procedures</i>.</p> <p>Many routines are already defined within PostgreSQL itself, but user-defined ones can also be added.</p>
Row	See <a href="#">Tuple</a> .
Savepoint	A special mark in the sequence of steps in a <i>transaction</i> . Data modifications after this point in time may be reverted to the time of the savepoint.

	For more information, see <a href="#">SAVEPOINT</a> .
Schema	<p>A schema is a namespace for <i>SQL objects</i>, which all reside in the same <i>database</i>. Each SQL object must reside in exactly one schema.</p> <p>All system-defined SQL objects reside in schema <code>pg_catalog</code>.</p> <p>More generically, the term <i>schema</i> is used to mean all data descriptions (<i>table</i> definitions, <i>constraints</i>, comments, etc) for a given <i>database</i> or subset thereof.</p> <p>For more information, see <a href="#">Section 5.9</a>.</p>
Segment	See <a href="#">File segment</a> .
Select	<p>The SQL command used to request data from a <i>database</i>. Normally, <code>SELECT</code> commands are not expected to modify the <i>database</i> in any way, but it is possible that <i>functions</i> invoked within the query could have side effects that do modify data.</p> <p>For more information, see <a href="#">SELECT</a>.</p>
Sequence (relation)	A type of relation that is used to generate values. Typically the generated values are sequential non-repeating numbers. They are commonly used to generate surrogate <i>primary key</i> values.
Server	<p>A computer on which PostgreSQL <i>instances</i> run. The term <i>server</i> denotes real hardware, a container, or a <i>virtual machine</i>.</p> <p>This term is sometimes used to refer to an instance or to a host.</p>
Session	A state that allows a client and a backend to interact, communicating over a <i>connection</i> .
Shared memory	<p>RAM which is used by the processes common to an <i>instance</i>. It mirrors parts of <i>database</i> files, provides a transient area for <i>WAL records</i>, and stores additional common information. Note that shared memory belongs to the complete instance, not to a single database.</p> <p>The largest part of shared memory is known as <i>shared buffers</i> and is used to mirror part of data files, organized into pages. When a page is modified, it is called a dirty page until it is written back to the file system.</p> <p>For more information, see <a href="#">Section 18.4.1</a>.</p>
SQL object	<p>Any object that can be created with a <code>CREATE</code> command. Most objects are specific to one database, and are commonly known as <i>local objects</i>.</p> <p>Most local objects belong to a specific <i>schema</i> in their containing database, such as <i>relations</i> (all types), <i>routines</i> (all types), data types, etc. The names of such objects of the same type in the same schema are enforced to be unique.</p> <p>There also exist local objects that do not belong to schemas; some examples are <i>extensions</i>, <i>data type casts</i>, and <i>foreign data wrappers</i>. The names of such objects of the same type are enforced to be unique within the database.</p> <p>Other object types, such as <i>roles</i>, <i>tablespaces</i>, replication origins, subscriptions for logical replication, and databases themselves are not local SQL objects since they exist entirely outside of any specific database; they</p>

	<p>are called <i>global objects</i>. The names of such objects are enforced to be unique within the whole database cluster.</p> <p>For more information, see <a href="#">Section 21.1</a>.</p>
SQL standard	A series of documents that define the SQL language.
Standby (server)	See <a href="#">Replica (server)</a> .
Stats collector (process)	<p>This process collects statistical information about the <i>instance</i>'s activities.</p> <p>For more information, see <a href="#">Section 26.2</a>.</p>
System catalog	<p>A collection of <i>tables</i> which describe the structure of all <i>SQL objects</i> of the instance. The system catalog resides in the schema <code>pg_catalog</code>. These tables contain data in internal representation and are not typically considered useful for user examination; a number of user-friendlier <i>views</i>, also in schema <code>pg_catalog</code>, offer more convenient access to some of that information, while additional tables and views exist in schema <code>information_schema</code> (see <a href="#">Chapter 34</a>) that expose some of the same and additional information as mandated by the <i>SQL standard</i>.</p> <p>For more information, see <a href="#">Section 5.9</a>.</p>
Table	<p>A collection of <i>tuples</i> having a common data structure (the same number of <i>attributes</i>, in the same order, having the same name and type per position). A table is the most common form of <i>relation</i> in PostgreSQL.</p> <p>For more information, see <a href="#">CREATE TABLE</a>.</p>
Tablespace	<p>A named location on the server file system. All <i>SQL objects</i> which require storage beyond their definition in the <i>system catalog</i> must belong to a single tablespace. Initially, a database cluster contains a single usable tablespace which is used as the default for all SQL objects, called <code>pg_default</code>.</p> <p>For more information, see <a href="#">Section 21.6</a>.</p>
Temporary table	<p><i>Tables</i> that exist either for the lifetime of a <i>session</i> or a <i>transaction</i>, as specified at the time of creation. The data in them is not visible to other sessions, and is not <i>logged</i>. Temporary tables are often used to store intermediate data for a multi-step operation.</p> <p>For more information, see <a href="#">CREATE TABLE</a>.</p>
TOAST	<p>A mechanism by which large attributes of table rows are split and stored in a secondary table, called the <i>TOAST table</i>. Each relation with large attributes has its own TOAST table.</p> <p>For more information, see <a href="#">Section 65.2</a>.</p>
Transaction	<p>A combination of commands that must act as a single <i>atomic</i> command: they all succeed or all fail as a single unit, and their effects are not visible to other <i>sessions</i> until the transaction is complete, and possibly even later, depending on the isolation level.</p> <p>For more information, see <a href="#">Section 13.2</a>.</p>
Transaction ID	<p>The numerical, unique, sequentially-assigned identifier that each transaction receives when it first causes a database modification. Frequently abbreviated as <i>xid</i>. When stored on disk, xids are only 32-bits wide, so only approximately four billion write transaction IDs can be generated; to permit the system to run for longer than that, <i>epochs</i> are</p>

used, also 32 bits wide. When the counter reaches the maximum xid value, it starts over at 3 (values under that are reserved) and the epoch value is incremented by one. In some contexts, the epoch and xid values are considered together as a single 64-bit value.

For more information, see [Section 8.19](#).

**Transactions per second (TPS)** Average number of transactions that are executed per second, totaled across all sessions active for a measured run. This is used as a measure of the performance characteristics of an instance.

**Trigger** A *function* which can be defined to execute whenever a certain operation (INSERT, UPDATE, DELETE, TRUNCATE) is applied to a *relation*. A trigger executes within the same *transaction* as the statement which invoked it, and if the function fails, then the invoking statement also fails.

For more information, see [CREATE TRIGGER](#).

**Tuple** A collection of *attributes* in a fixed order. That order may be defined by the *table* (or other *relation*) where the tuple is contained, in which case the tuple is often called a *row*. It may also be defined by the structure of a result set, in which case it is sometimes called a *record*.

**Unique constraint** A type of *constraint* defined on a *relation* which restricts the values allowed in one or a combination of columns so that each value or combination of values can only appear once in the relation — that is, no other row in the relation contains values that are equal to those.

Because *null values* are not considered equal to each other, multiple rows with null values are allowed to exist without violating the unique constraint.

**Unlogged** The property of certain *relations* that the changes to them are not reflected in the *WAL*. This disables replication and crash recovery for these relations.

The primary use of unlogged tables is for storing transient work data that must be shared across processes.

*Temporary tables* are always unlogged.

**Update** An SQL command used to modify *rows* that may already exist in a specified *table*. It cannot create or remove rows.

For more information, see [UPDATE](#).

**User** A *role* that has the LOGIN privilege.

**User mapping** The translation of login credentials in the local *database* to credentials in a remote data system defined by a *foreign data wrapper*.

For more information, see [CREATE USER MAPPING](#).

**Vacuum** The process of removing outdated *tuple versions* from tables or materialized views, and other closely related processing required by PostgreSQL's implementation of *MVCC*. This can be initiated through the use of the VACUUM command, but can also be handled automatically via *autovacuum* processes.

For more information, see [Section 23.1](#) .

**View** A *relation* that is defined by a SELECT statement, but has no storage of its own. Any time a query references a view, the definition of the view is

		substituted into the query as if the user had typed it as a subquery instead of the name of the view.  For more information, see <a href="#">CREATE VIEW</a> .
Visibility map (fork)		A storage structure that keeps metadata about each data page of a table's main fork. The visibility map entry for each page stores two bits: the first one ( <code>all-visible</code> ) indicates that all tuples in the page are visible to all transactions. The second one ( <code>all-frozen</code> ) indicates that all tuples in the page are marked frozen.
WAL		See <a href="#">Write-ahead log</a> .
WAL archiver (process)		A process that saves copies of <a href="#">WAL files</a> for the purpose of creating backups or keeping <a href="#">replicas</a> current.  For more information, see <a href="#">Section 24.3</a> .
WAL file		Also known as <a href="#">WAL segment</a> or <a href="#">WAL segment file</a> . Each of the sequentially-numbered files that provide storage space for <a href="#">WAL</a> . The files are all of the same predefined size and are written in sequential order, interspersing changes as they occur in multiple simultaneous sessions. If the system crashes, the files are read in order, and each of the changes is replayed to restore the system to the state it was in before the crash.  Each WAL file can be released after a <a href="#">checkpoint</a> writes all the changes in it to the corresponding data files. Releasing the file can be done either by deleting it, or by changing its name so that it will be used in the future, which is called <a href="#">recycling</a> .  For more information, see <a href="#">Section 28.5</a> .
WAL record		A low-level description of an individual data change. It contains sufficient information for the data change to be re-executed ( <a href="#">replayed</a> ) in case a system failure causes the change to be lost. WAL records use a non-printable binary format.  For more information, see <a href="#">Section 28.5</a> .
WAL segment		See <a href="#">WAL file</a> .
WAL writer (process)		A process that writes <a href="#">WAL records</a> from <a href="#">shared memory</a> to <a href="#">WAL files</a> .  For more information, see <a href="#">Section 18.5</a> .
Window (routine)	function	A type of <a href="#">function</a> used in a <a href="#">query</a> that applies to a <a href="#">partition</a> of the query's <a href="#">result set</a> ; the function's result is based on values found in <a href="#">rows</a> of the same partition or frame.  All <a href="#">aggregate functions</a> can be used as window functions, but window functions can also be used to, for example, give ranks to each of the rows in the partition. Also known as <a href="#">analytic functions</a> .  For more information, see <a href="#">Section 3.5</a> .
Write-ahead log		The journal that keeps track of the changes in the <a href="#">database cluster</a> as user- and system-invoked operations take place. It comprises many individual <a href="#">WAL records</a> written sequentially to <a href="#">WAL files</a> .

---

# Appendix N. Color Support

Most programs in the PostgreSQL package can produce colored console output. This appendix describes how that is configured.

## N.1. When Color is Used

To use colored output, set the environment variable `PG_COLORS` as follows:

1. If the value is `always`, then color is used.
2. If the value is `auto` and the standard error stream is associated with a terminal device, then color is used.
3. Otherwise, color is not used.

## N.2. Configuring the Colors

The actual colors to be used are configured using the environment variable `PG_COLORS` (note plural). The value is a colon-separated list of `key=value` pairs. The keys specify what the color is to be used for. The values are SGR (Select Graphic Rendition) specifications, which are interpreted by the terminal.

The following keys are currently in use:

`error`

used to highlight the text “error” in error messages

`warning`

used to highlight the text “warning” in warning messages

`locus`

used to highlight location information (e.g., program name and file name) in messages

The default value is `error=01;31:warning=01;35:locus=01` (01;31 = bold red, 01;35 = bold magenta, 01 = bold default color).

### Tip

This color specification format is also used by other software packages such as GCC, GNU coreutils, and GNU grep.

---

# Appendix O. Obsolete or Renamed Features

Functionality is sometimes removed from PostgreSQL, feature, setting and file names sometimes change, or documentation moves to different places. This section directs users coming from old versions of the documentation or from external links to the appropriate new location for the information they need.

## O.1. `recovery.conf` file merged into `postgresql.conf`

Postgres Pro 11 and below used a configuration file named `recovery.conf` to manage replicas and standbys. Support for this file was removed in Postgres Pro 12. See [the release notes for PostgreSQL 12](#) for details on this change.

On Postgres Pro 12 and above, [archive recovery](#), [streaming replication](#), and [PITR](#) are configured using [normal server configuration parameters](#). These are set in `postgresql.conf` or via `ALTER SYSTEM` like any other parameter.

The server will not start if a `recovery.conf` exists.

The `trigger_file` setting has been renamed to [promote\\_trigger\\_file](#).

The `standby_mode` setting has been removed. A `standby.signal` file in the data directory is used instead. See [Standby Server Operation](#) for details.

## O.2. `pg_xlogdump` renamed to `pg_waldump`

Postgres Pro 9.6 and below provided a command named `pg_xlogdump` to read write-ahead-log (WAL) files. This command was renamed to `pg_waldump`, see [pg\\_waldump](#) for documentation of `pg_waldump` and see [the release notes for PostgreSQL 10](#) for details on this change.

## O.3. `pg_resetxlog` renamed to `pg_resetwal`

Postgres Pro 9.6 and below provided a command named `pg_resetxlog` to reset the write-ahead-log (WAL) files. This command was renamed to `pg_resetwal`, see [pg\\_resetwal](#) for documentation of `pg_resetwal` and see [the release notes for PostgreSQL 10](#) for details on this change.

## O.4. `pg_receivexlog` renamed to `pg_receivewal`

Postgres Pro 9.6 and below provided a command named `pg_receivexlog` to fetch write-ahead-log (WAL) files. This command was renamed to `pg_receivewal`, see [pg\\_receivewal](#) for documentation of `pg_receivewal` and see [the release notes for PostgreSQL 10](#) for details on this change.

---

# Bibliography

Selected references and readings for SQL and PostgreSQL.

Some white papers and technical reports from the original POSTGRES development team are available at the University of California, Berkeley, Computer Science Department [web site](#).

## SQL Reference Books

- [bowman01] *The Practical SQL Handbook*. Using SQL Variants. Fourth Edition. Judith Bowman, Sandra Emerson, and Marcy Darnovsky. ISBN 0-201-70309-2. Addison-Wesley Professional. 2001.
- [date97] *A Guide to the SQL Standard*. A user's guide to the standard database language SQL. Fourth Edition. C. J. Date and Hugh Darwen. ISBN 0-201-96426-0. Addison-Wesley. 1997.
- [date04] *An Introduction to Database Systems*. Eighth Edition. C. J. Date. ISBN 0-321-19784-4. Addison-Wesley. 2003.
- [elma04] *Fundamentals of Database Systems*. Fourth Edition. Ramez Elmasri and Shamkant Navathe. ISBN 0-321-12226-7. Addison-Wesley. 2003.
- [melt93] *Understanding the New SQL*. A complete guide. Jim Melton and Alan R. Simon. ISBN 1-55860-245-3. Morgan Kaufmann. 1993.
- [ull88] *Principles of Database and Knowledge-Base Systems*. Classical Database Systems. Jeffrey D. Ullman. Volume 1. Computer Science Press. 1988.
- [sqltr-19075-6] *SQL Technical Report*. Part 6: SQL support for JavaScript Object Notation (JSON). First Edition. 2017.

## PostgreSQL-specific Documentation

- [sim98] *Enhancement of the ANSI SQL Implementation of PostgreSQL*. Stefan Simkovic. Department of Information Systems, Vienna University of Technology. Vienna, Austria. November 29, 1998.
- [yu95] *The Postgres95. User Manual*. A. Yu and J. Chen. University of California. Berkeley, California. Sept. 5, 1995.
- [fong] *The design and implementation of the POSTGRES query optimizer*. Zelaine Fong. University of California, Berkeley, Computer Science Department.

## Proceedings and Articles

- [ports12] "[Serializable Snapshot Isolation in PostgreSQL](#)". D. Ports and K. Grittner. VLDB Conference, August 2012.
- [berenson95] "[A Critique of ANSI SQL Isolation Levels](#)". H. Berenson, P. Bernstein, J. Gray, J. Melton, E. O'Neil, and P. O'Neil. ACM-SIGMOD Conference on Management of Data, June 1995.
- [olson93] *Partial indexing in POSTGRES: research project*. Nels Olson. UCB Engin T7.49.1993 O676. University of California. Berkeley, California. 1993.
- [ong90] "A Unified Framework for Version Modeling Using Production Rules in a Database System". L. Ong and J. Goh. *ERL Technical Memorandum M90/33*. University of California. Berkeley, California. April, 1990.
- [rowe87] "[The POSTGRES data model](#)". L. Rowe and M. Stonebraker. VLDB Conference, Sept. 1987.

- [seshadri95] "*Generalized Partial Indexes*". P. Seshadri and A. Swami. Eleventh International Conference on Data Engineering, 6-10 March 1995. Cat. No.95CH35724. IEEE Computer Society Press. Los Alamitos, California. 1995. 420-7.
- [ston86] "*The design of POSTGRES*". M. Stonebraker and L. Rowe. ACM-SIGMOD Conference on Management of Data, May 1986.
- [ston87a] "The design of the POSTGRES. rules system". M. Stonebraker, E. Hanson, and C. H. Hong. IEEE Conference on Data Engineering, Feb. 1987.
- [ston87b] "*The design of the POSTGRES storage system*". M. Stonebraker. VLDB Conference, Sept. 1987.
- [ston89] "*A commentary on the POSTGRES rules system*". M. Stonebraker, M. Hearst, and S. Potamianos. *SIGMOD Record* 18(3). Sept. 1989.
- [ston89b] "*The case for partial indexes*". M. Stonebraker. *SIGMOD Record* 18(4). Dec. 1989. 4-11.
- [ston90a] "*The implementation of POSTGRES*". M. Stonebraker, L. A. Rowe, and M. Hirohama. *Transactions on Knowledge and Data Engineering* 2(1). IEEE. March 1990.
- [ston90b] "*On Rules, Procedures, Caching and Views in Database Systems*". M. Stonebraker, A. Jhingran, J. Goh, and S. Potamianos. ACM-SIGMOD Conference on Management of Data, June 1990.
