   auto_explain.log_level selects the log level at which auto_explain will log the query plan. Valid values are DEBUG5, DEBUG4, DEBUG3, DEBUG2, DEBUG1, INFO, NOTICE, WARNING, and LOG. The default is LOG. Only superusers can change this setting.

auto_explain.log_nested_statements (boolean)
   auto_explain.log_nested_statements causes nested statements (statements executed inside a function) to be considered for logging. When it is off, only top-level query plans are logged. This parameter is off by default. Only superusers can change this setting.

auto_explain.sample_rate (real)
   auto_explain.sample_rate causes auto_explain to only explain a fraction of the statements in each session. The default is 1, meaning explain all the queries. In case of nested statements, either all will be explained or none. Only superusers can change this setting.

In ordinary usage, these parameters are set in postgresql.conf, although superusers can alter them on-the-fly within their own sessions. Typical usage might be:

```
# postgresql.conf
session_preload_libraries = 'auto_explain'
auto_explain.log_min_duration = '3s'
```

F.4.2. Example

```
postgres=# LOAD 'auto_explain';
postgres=# SET auto_explain.log_min_duration = 0;
postgres=# SET auto_explain.log_analyze = true;
postgres=# SELECT count(*)
    FROM pg_class, pg_index
    WHERE oid = indrelid AND indisunique;
```

This might produce log output such as:

```
LOG: duration: 0.196 ms planning: 0.548 ms plan:
   Query Text: SELECT count(*)
   FROM pg_class, pg_index
   WHERE oid = indrelid AND indisunique;
   Aggregate (cost=16.79..16.80 rows=1 width=0) (actual time=3.626..3.627 rows=1 loops=1)
      ->  Hash Join (cost=4.17..16.55 rows=92 width=0) (actual time=3.349..3.594 rows=92 loops=1)
         Hash Cond: (pg_class.oid = pg_index.indrelid)
         ->  Seq Scan on pg_class (cost=0.00..9.55 rows=255 width=4) (actual time=0.016..0.140 rows=255 loops=1)
         ->  Hash (cost=3.02..3.02 rows=92 width=4) (actual time=3.238..3.238 rows=92 loops=1)
            Buckets: 1024 Batches: 1 Memory Usage: 4kB
               ->  Seq Scan on pg_index (cost=0.00..3.02 rows=92 width=4) (actual time=0.008..3.187 rows=92 loops=1)
                  Filter: indisunique
```

Note that Postgres Pro added a new field to the output to show planning time.

**F.5. bloom**

*bloom* provides an index access method based on *Bloom filters*.

A Bloom filter is a space-efficient data structure that is used to test whether an element is a member of a set. In the case of an index access method, it allows fast exclusion of non-matching tuples via signatures whose size is determined at index creation.

A signature is a lossy representation of the indexed attribute(s), and as such is prone to reporting false positives; that is, it may be reported that an element is in the set, when it is not. So index search results must always be rechecked using the actual attribute values from the heap entry. Larger signatures reduce the odds of a false positive and thus reduce the number of useless heap visits, but of course also make the index larger and hence slower to scan.

This type of index is most useful when a table has many attributes and queries test arbitrary combinations of them. A traditional btree index is faster than a bloom index, but it can require many btree indexes to support all possible queries where one needs only a single bloom index. Note however that bloom indexes only support equality queries, whereas btree indexes can also perform inequality and range searches.

**F.5.1. Parameters**

A *bloom* index accepts the following parameters in its *WITH* clause:

- **length**
  
  Length of each signature (index entry) in bits. It is rounded up to the nearest multiple of 16. The default is 80 bits and the maximum is 4096.

- **col1 — col32**
  
  Number of bits generated for each index column. Each parameter’s name refers to the number of the index column that it controls. The default is 2 bits and the maximum is 4095. Parameters for index columns not actually used are ignored.

**F.5.2. Examples**

This is an example of creating a bloom index:

```
CREATE INDEX bloomidx ON tbloom USING bloom (i1,i2,i3)
  WITH (length=80, col1=2, col2=2, col3=4);
```

The index is created with a signature length of 80 bits, with attributes i1 and i2 mapped to 2 bits, and attribute i3 mapped to 4 bits. We could have omitted the *length*, *col1*, and *col2* specifications since those have the default values.

Here is a more complete example of bloom index definition and usage, as well as a comparison with equivalent btree indexes. The bloom index is considerably smaller than the btree index, and can perform better.

```
=# CREATE TABLE tbloom AS
    SELECT
      (random() * 1000000)::int as i1,
      (random() * 1000000)::int as i2,
      (random() * 1000000)::int as i3,
      (random() * 1000000)::int as i4,
      (random() * 1000000)::int as i5,
      (random() * 1000000)::int as i6
    FROM
      generate_series(1,10000000);
    SELECT 10000000
```

A sequential scan over this large table takes a long time:

```sql
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
```

---

```
 Seq Scan on tbloom  (cost=0.00..2137.14 rows=3 width=24) (actual time=16.971..16.971 rows=0 loops=1)
   Filter: ((i2 = 898732) AND (i5 = 123451))
 Rows Removed by Filter: 100000
Planning Time: 0.346 ms
Execution Time: 16.988 ms
(5 rows)
```

Even with the btree index defined the result will still be a sequential scan:

```sql
=# CREATE INDEX btreeidx ON tbloom (i1, i2, i3, i4, i5, i6);
CREATE INDEX
=# SELECT pg_size_pretty(pg_relation_size('btreeidx'));
pg_size_pretty
----------------
3976 kB
(1 row)
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
```

---

```
 Seq Scan on tbloom  (cost=0.00..2137.00 rows=2 width=24) (actual time=12.805..12.805 rows=0 loops=1)
   Filter: ((i2 = 898732) AND (i5 = 123451))
 Rows Removed by Filter: 100000
Planning Time: 0.138 ms
Execution Time: 12.817 ms
(5 rows)
```

Having the bloom index defined on the table is better than btree in handling this type of search:

```sql
=# CREATE INDEX bloomidx ON tbloom USING bloom (i1, i2, i3, i4, i5, i6);
CREATE INDEX
=# SELECT pg_size_pretty(pg_relation_size('bloomidx'));
pg_size_pretty
----------------
1584 kB
(1 row)
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
```

---

```
 Bitmap Heap Scan on tbloom  (cost=1792.00..1799.69 rows=2 width=24) (actual time=0.388..0.388 rows=0 loops=1)
   Recheck Cond: ((i2 = 898732) AND (i5 = 123451))
 Rows Removed by Index Recheck: 29
 Heap Blocks: exact=28
 -> Bitmap Index Scan on bloomidx  (cost=0.00..1792.00 rows=2 width=0) (actual time=0.356..0.356 rows=29 loops=1)
    Index Cond: ((i2 = 898732) AND (i5 = 123451))
Planning Time: 0.099 ms
```

2249
Now, the main problem with the btree search is that btree is inefficient when the search conditions do not constrain the leading index column(s). A better strategy for btree is to create a separate index on each column. Then the planner will choose something like this:

```sql
=# CREATE INDEX btreeidx1 ON tbloom (i1);
CREATE INDEX
=# CREATE INDEX btreeidx2 ON tbloom (i2);
CREATE INDEX
=# CREATE INDEX btreeidx3 ON tbloom (i3);
CREATE INDEX
=# CREATE INDEX btreeidx4 ON tbloom (i4);
CREATE INDEX
=# CREATE INDEX btreeidx5 ON tbloom (i5);
CREATE INDEX
=# CREATE INDEX btreeidx6 ON tbloom (i6);
CREATE INDEX
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
```

Although this query runs much faster than with either of the single indexes, we pay a penalty in index size. Each of the single-column btree indexes occupies 2 MB, so the total space needed is 12 MB, eight times the space used by the bloom index.

### F.5.3. Operator Class Interface

An operator class for bloom indexes requires only a hash function for the indexed data type and an equality operator for searching. This example shows the operator class definition for the `text` data type:

```sql
CREATE OPERATOR CLASS text_ops
DEFAULT FOR TYPE text USING bloom AS
    OPERATOR 1 ==(text, text),
    FUNCTION 1 hashtext(text);
```

### F.5.4. Limitations

- Only operator classes for `int4` and `text` are included with the module.
- Only the `=` operator is supported for search. But it is possible to add support for arrays with union and intersection operations in the future.
- `bloom` access method doesn't support `UNIQUE` indexes.
bloom access method doesn't support searching for NULL values.

F.5.5. Authors

Teodor Sigaev <teodor@postgrespro.ru>, Postgres Professional, Moscow, Russia
Alexander Korotkov <a.korotkov@postgrespro.ru>, Postgres Professional, Moscow, Russia
Oleg Bartunov <obartunov@postgrespro.ru>, Postgres Professional, Moscow, Russia

F.6. btree_gin

btree_gin provides sample GIN operator classes that implement B-tree equivalent behavior for the data types int2, int4, int8, float4, float8, timestamp with time zone, timestamp without time zone, time with time zone, time without time zone, date, interval, oid, money, "char", varchar, text, bytea, bit, varbit, macaddr, macaddr8, inet, cidr, uuid, name, bool, bpchar, and all enum types.

In general, these operator classes will not outperform the equivalent standard B-tree index methods, and they lack one major feature of the standard B-tree code: the ability to enforce uniqueness. However, they are useful for GIN testing and as a base for developing other GIN operator classes. Also, for queries that test both a GIN-indexable column and a B-tree-indexable column, it might be more efficient to create a multicolumn GIN index that uses one of these operator classes than to create two separate indexes that would have to be combined via bitmap ANDing.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.6.1. Example Usage

```sql
CREATE TABLE test (a int4);
-- create index
CREATE INDEX testidx ON test USING GIN (a);
-- query
SELECT * FROM test WHERE a < 10;
```

F.6.2. Authors

Teodor Sigaev (<teodor@stack.net>) and Oleg Bartunov (<oleg@sai.msu.su>). See http://www.sai.msu.su/~megera/oddmuse/index.cgi/Gin for additional information.

F.7. btree_gist

btree_gist provides GiST index operator classes that implement B-tree equivalent behavior for the data types int2, int4, int8, float4, float8, numeric, timestamp with time zone, timestamp without time zone, time with time zone, time without time zone, date, interval, oid, money, char, varchar, text, bytea, bit, varbit, macaddr, macaddr8, inet, cidr, uuid, and all enum types.

In general, these operator classes will not outperform the equivalent standard B-tree index methods, and they lack one major feature of the standard B-tree code: the ability to enforce uniqueness. However, they provide other features that are not available with a B-tree index, as described below. Also, these operator classes are useful when a multicolumn GiST index is needed, wherein some of the columns are of data types that are only indexable with GiST but other columns are just simple data types. Lastly, these operator classes are useful for GiST testing and as a base for developing other GiST operator classes.

In addition to the typical B-tree search operators, btree_gist also provides index support for <> ("not equals"). This may be useful in combination with an exclusion constraint, as described below.

Also, for data types for which there is a natural distance metric, btree_gist defines a distance operator <->, and provides GiST index support for nearest-neighbor searches using this operator. Distance operators are provided for int2, int4, int8, float4, float8, timestamp with time zone, timestamp without time zone, time without time zone, date, interval, oid, and money.
Additional Supplied Modules

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

**F.7.1. Example Usage**

Simple example using `btree_gist` instead of `btree`:

```sql
CREATE TABLE test (a int4);
-- create index
CREATE INDEX testidx ON test USING GIST (a);
-- query
SELECT * FROM test WHERE a < 10;
-- nearest-neighbor search: find the ten entries closest to "42"
SELECT *, a <-> 42 AS dist FROM test ORDER BY a <-> 42 LIMIT 10;
```

Use an exclusion constraint to enforce the rule that a cage at a zoo can contain only one kind of animal:

```sql
=> CREATE TABLE zoo (cage INTEGER, animal TEXT,
    EXCLUDE USING GIST (cage WITH =, animal WITH <>);
)
=> INSERT INTO zoo VALUES(123, 'zebra');
INSERT 0 1
=> INSERT INTO zoo VALUES(123, 'zebra');
INSERT 0 1
=> INSERT INTO zoo VALUES(123, 'lion');
ERROR: conflicting key value violates exclusion constraint "zoo_cage_animal_excl"
DETAIL: Key (cage, animal)=(123, lion) conflicts with existing key (cage,
    animal)=(123, zebra).
=> INSERT INTO zoo VALUES(124, 'lion');
INSERT 0 1
```

**F.7.2. Authors**

Teodor Sigaev (<teodor@stack.net>), Oleg Bartunov (<oleg@sai.msu.su>), Janko Richter (<jankorichter@yahoo.de>), and Paul Jungwirth (<pj@illuminatedcomputing.com>). See [http://www.sai.msu.su/~megera/postgres/gist/](http://www.sai.msu.su/~megera/postgres/gist/) for additional information.

**F.8. citext**

The `citext` module provides a case-insensitive character string type, `citext`. Essentially, it internally calls `lower` when comparing values. Otherwise, it behaves almost exactly like `text`.

**Tip**

Consider using nondeterministic collations (see Section 22.2.2.4) instead of this module. They can be used for case-insensitive comparisons, accent-insensitive comparisons, and other combinations, and they handle more Unicode special cases correctly.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

**F.8.1. Rationale**

The standard approach to doing case-insensitive matches in Postgres Pro has been to use the `lower` function when comparing values, for example

```sql
SELECT * FROM tab WHERE lower(col) = LOWER(?);
```
Additional Supplied Modules

This works reasonably well, but has a number of drawbacks:

- It makes your SQL statements verbose, and you always have to remember to use `lower` on both the column and the query value.
- It won’t use an index, unless you create a functional index using `lower`.
- If you declare a column as `UNIQUE` or `PRIMARY KEY`, the implicitly generated index is case-sensitive. So it’s useless for case-insensitive searches, and it won’t enforce uniqueness case-insensitively.

The `citext` data type allows you to eliminate calls to `lower` in SQL queries, and allows a primary key to be case-insensitive. `citext` is locale-aware, just like `text`, which means that the matching of upper case and lower case characters is dependent on the rules of the database's `LC_CTYPE` setting. Again, this behavior is identical to the use of `lower` in queries. But because it’s done transparently by the data type, you don't have to remember to do anything special in your queries.

**F.8.2. How to Use It**

Here's a simple example of usage:

```sql
CREATE TABLE users (  
nick CITEXT PRIMARY KEY,  
pass TEXT   NOT NULL
);

INSERT INTO users VALUES ( 'larry', sha256(random()::text::bytea) );
INSERT INTO users VALUES ( 'Tom',    sha256(random()::text::bytea) );
INSERT INTO users VALUES ( 'Damian', sha256(random()::text::bytea) );
INSERT INTO users VALUES ( 'NEAL',   sha256(random()::text::bytea) );
INSERT INTO users VALUES ( 'Bjørn',  sha256(random()::text::bytea) );

SELECT * FROM users WHERE nick = 'Larry';
```

The `SELECT` statement will return one tuple, even though the `nick` column was set to `larry` and the query was for `Larry`.

**F.8.3. String Comparison Behavior**

`citext` performs comparisons by converting each string to lower case (as though `lower` were called) and then comparing the results normally. Thus, for example, two strings are considered equal if `lower` would produce identical results for them.

In order to emulate a case-insensitive collation as closely as possible, there are `citext`-specific versions of a number of string-processing operators and functions. So, for example, the regular expression operators `~` and `~*` exhibit the same behavior when applied to `citext`; they both match case-insensitively. The same is true for `!~` and `!~*`, as well as for the `LIKE` operators `~~` and `~~*`, and `!~~` and `!~~*`. If you'd like to match case-sensitively, you can cast the operator's arguments to `text`.

Similarly, all of the following functions perform matching case-insensitively if their arguments are `citext`:

- `regexp_match()`
- `regexp_matches()`
- `regexp_replace()`
- `regexp_split_to_array()`
- `regexp_split_to_table()`
- `replace()`
- `split_part()`
- `strpos()`
- `translate()`
For the regexp functions, if you want to match case-sensitively, you can specify the “c” flag to force a case-sensitive match. Otherwise, you must cast to text before using one of these functions if you want case-sensitive behavior.

F.8.4. Limitations

- citext’s case-folding behavior depends on the LC_CTYPE setting of your database. How it compares values is therefore determined when the database is created. It is not truly case-insensitive in the terms defined by the Unicode standard. Effectively, what this means is that, as long as you’re happy with your collation, you should be happy with citext's comparisons. But if you have data in different languages stored in your database, users of one language may find their query results are not as expected if the collation is for another language.

- As of PostgreSQL 9.1, you can attach a COLLATE specification to citext columns or data values. Currently, citext operators will honor a non-default COLLATE specification while comparing case-folded strings, but the initial folding to lower case is always done according to the database's LC_CTYPE setting (that is, as though COLLATE "default" were given). This may be changed in a future release so that both steps follow the input COLLATE specification.

- citext is not as efficient as text because the operator functions and the B-tree comparison functions must make copies of the data and convert it to lower case for comparisons. Also, only text can support B-Tree deduplication. However, citext is slightly more efficient than using lower to get case-insensitive matching.

- citext doesn't help much if you need data to compare case-sensitively in some contexts and case-insensitively in other contexts. The standard answer is to use the text type and manually use the lower function when you need to compare case-insensitively; this works all right if case-insensitive comparison is needed only infrequently. If you need case-insensitive behavior most of the time and case-sensitive infrequently, consider storing the data as citext and explicitly casting the column to text when you want case-sensitive comparison. In either situation, you will need two indexes if you want both types of searches to be fast.

- The schema containing the citext operators must be in the current search_path (typically public); if it is not, the normal case-sensitive text operators will be invoked instead.

- The approach of lower-casing strings for comparison does not handle some Unicode special cases correctly, for example when one upper-case letter has two lower-case letter equivalents. Unicode distinguishes between case mapping and case folding for this reason. Use nondeterministic collations instead of citext to handle that correctly.

F.8.5. Author

David E. Wheeler <david@kineticode.com>

Inspired by the original citext module by Donald Fraser.

F.9. cube

This module implements a data type cube for representing multidimensional cubes.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.9.1. Syntax

Table F.2 shows the valid external representations for the cube type. x, y, etc. denote floating-point numbers.

Table F.2. Cube External Representations

<table>
<thead>
<tr>
<th>External Syntax</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>A one-dimensional point (or, zero-length one-dimensional interval)</td>
</tr>
</tbody>
</table>
### External Syntax

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>(x)</td>
<td>Same as above</td>
</tr>
<tr>
<td>x1, x2, ..., xn</td>
<td>A point in n-dimensional space, represented internally as a zero-volume cube</td>
</tr>
<tr>
<td>(x1, x2, ..., xn)</td>
<td>Same as above</td>
</tr>
<tr>
<td>(x), (y)</td>
<td>A one-dimensional interval starting at x and ending at y or vice versa; the order does not matter</td>
</tr>
<tr>
<td>[(x), (y)]</td>
<td>Same as above</td>
</tr>
<tr>
<td>(x1, ..., xn), (y1, ..., yn)</td>
<td>An n-dimensional cube represented by a pair of its diagonally opposite corners</td>
</tr>
<tr>
<td>[(x1, ..., xn), (y1, ..., yn)]</td>
<td>Same as above</td>
</tr>
</tbody>
</table>

It does not matter which order the opposite corners of a cube are entered in. The `cube` functions automatically swap values if needed to create a uniform “lower left — upper right” internal representation. When the corners coincide, `cube` stores only one corner along with an “is point” flag to avoid wasting space.

White space is ignored on input, so [(x), (y)] is the same as [(x), (y)].

### F.9.2. Precision

Values are stored internally as 64-bit floating point numbers. This means that numbers with more than about 16 significant digits will be truncated.

### F.9.3. Usage

Table F.3 shows the specialized operators provided for type `cube`.

#### Table F.3. Cube Operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cube &amp;&amp; cube → boolean</td>
<td>Do the cubes overlap?</td>
</tr>
<tr>
<td>cube @&gt; cube → boolean</td>
<td>Does the first cube contain the second?</td>
</tr>
<tr>
<td>cube &lt;@ cube → boolean</td>
<td>Is the first cube contained in the second?</td>
</tr>
<tr>
<td>cube -&gt; integer → float8</td>
<td>Extracts the n-th coordinate of the cube (counting from 1).</td>
</tr>
<tr>
<td>cube -&gt; integer → float8</td>
<td>Extracts the n-th coordinate of the cube, counting in the following way: n = 2 * k - 1 means lower bound of k-th dimension, n = 2 * k means upper bound of k-th dimension. Negative n denotes the inverse value of the corresponding positive coordinate. This operator is designed for KNN-GiST support.</td>
</tr>
<tr>
<td>cube &lt;-&gt; cube → float8</td>
<td>Computes the Euclidean distance between the two cubes.</td>
</tr>
<tr>
<td>cube &lt;-&gt; cube → float8</td>
<td>Computes the taxicab (L-1 metric) distance between the two cubes.</td>
</tr>
<tr>
<td>cube &lt;-&gt; cube → float8</td>
<td></td>
</tr>
</tbody>
</table>

2255
In addition to the above operators, the usual comparison operators shown in Table 9.1 are available for type cube. These operators first compare the first coordinates, and if those are equal, compare the second coordinates, etc. They exist mainly to support the b-tree index operator class for cube, which can be useful for example if you would like a UNIQUE constraint on a cube column. Otherwise, this ordering is not of much practical use.

The cube module also provides a GiST index operator class for cube values. A cube GiST index can be used to search for values using the =, &&, @>, and @@ operators in WHERE clauses.

In addition, a cube GiST index can be used to find nearest neighbors using the metric operators <->, <#, and <=> in ORDER BY clauses. For example, the nearest neighbor of the 3-D point (0.5, 0.5, 0.5) could be found efficiently with:

```sql
SELECT c FROM test ORDER BY c <-> cube(array[0.5,0.5,0.5]) LIMIT 1;
```

The ~> operator can also be used in this way to efficiently retrieve the first few values sorted by a selected coordinate. For example, to get the first few cubes ordered by the first coordinate (lower left corner) ascending one could use the following query:

```sql
SELECT c FROM test ORDER BY c ~> 1 LIMIT 5;
```

And to get 2-D cubes ordered by the first coordinate of the upper right corner descending:

```sql
SELECT c FROM test ORDER BY c ~> 3 DESC LIMIT 5;
```

Table F.4 shows the available functions.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>Example(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>cube(float8) → cube</code></td>
<td>Makes a one dimensional cube with both coordinates the same.</td>
<td><code>cube(1) → (1)</code></td>
</tr>
<tr>
<td><code>cube(float8, float8) → cube</code></td>
<td>Makes a one dimensional cube.</td>
<td><code>cube(1, 2) → (1, 2)</code></td>
</tr>
<tr>
<td><code>cube(float8[]) → cube</code></td>
<td>Makes a zero-volume cube using the coordinates defined by the array.</td>
<td><code>cube(ARRAY[1,2,3]) → (1, 2, 3)</code></td>
</tr>
<tr>
<td><code>cube(float8[], float8[]) → cube</code></td>
<td>Makes a cube with upper right and lower left coordinates as defined by the two arrays, which must be of the same length.</td>
<td><code>cube(ARRAY[1,2], ARRAY[3,4]) → (1, 2), (3, 4)</code></td>
</tr>
<tr>
<td><code>cube(cube, float8) → cube</code></td>
<td>Makes a new cube by adding a dimension on to an existing cube, with the same values for both endpoints of the new coordinate. This is useful for building cubes piece by piece from calculated values.</td>
<td><code>cube('(1,2),(3,4)':::cube, 5) → (1, 2, 5), (3, 4, 5)</code></td>
</tr>
<tr>
<td><code>cube(cube, float8, float8) → cube</code></td>
<td>Makes a new cube by adding a dimension on to an existing cube. This is useful for building cubes piece by piece from calculated values.</td>
<td></td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
<td>Example(s)</td>
</tr>
<tr>
<td>----------</td>
<td>-------------</td>
<td>------------</td>
</tr>
<tr>
<td>cube('1,2), (3,4)' :: cube, 5, 6</td>
<td>→ (1, 2, 5), (3, 4, 6)</td>
<td></td>
</tr>
<tr>
<td>cube_dim (cube) → integer</td>
<td>Returns the number of dimensions of the cube.</td>
<td>cube_dim('(1,2), (3,4)') → 2</td>
</tr>
<tr>
<td>cube_ll_coord (cube, integer) → float8</td>
<td>Returns the n-th coordinate value for the lower left corner of the cube.</td>
<td>cube_ll_coord('(1,2), (3,4)', 2) → 2</td>
</tr>
<tr>
<td>cube_ur_coord (cube, integer) → float8</td>
<td>Returns the n-th coordinate value for the upper right corner of the cube.</td>
<td>cube_ur_coord('(1,2), (3,4)', 2) → 4</td>
</tr>
<tr>
<td>cube_is_point (cube) → boolean</td>
<td>Returns true if the cube is a point, that is, the two defining corners are the same.</td>
<td>cube_is_point(cube(1,1)) → t</td>
</tr>
<tr>
<td>cube_distance (cube, cube) → float8</td>
<td>Returns the distance between two cubes. If both cubes are points, this is the normal distance function.</td>
<td>cube_distance('(1,2)', '(3,4)') → 2.8284271247461903</td>
</tr>
<tr>
<td>cube_subset (cube, integer[]) → cube</td>
<td>Makes a new cube from an existing cube, using a list of dimension indexes from an array. Can be used to extract the endpoints of a single dimension, or to drop dimensions, or to reorder them as desired.</td>
<td>cube_subset(cube('(1,3,5), (6,7,8)'), ARRAY[2]) → (3), (7)</td>
</tr>
<tr>
<td>cube_union (cube, cube) → cube</td>
<td>Produces the union of two cubes.</td>
<td>cube_union('(1,2)', '(3,4)') → (1, 2), (3, 4)</td>
</tr>
<tr>
<td>cube_inter (cube, cube) → cube</td>
<td>Produces the intersection of two cubes.</td>
<td>cube_inter('(1,2)', '(3,4)') → (3, 4), (1, 2)</td>
</tr>
<tr>
<td>cube_enlarge (c cube, r double, n integer) → cube</td>
<td>Increases the size of the cube by the specified radius r in at least n dimensions. If the radius is negative the cube is shrunk instead. All defined dimensions are changed by the radius r. Lower-left coordinates are decreased by r and upper-right coordinates are increased by r. If a lower-left coordinate is increased to more than the corresponding upper-right coordinate (this can only happen when r &lt; 0) than both coordinates are set to their average. If n is greater than the number of defined dimensions and the cube is being enlarged (r &gt; 0), then extra dimensions are added to make n altogether; 0 is used as the initial value for the extra coordinates. This function is useful for creating bounding boxes around a point for searching for nearby points.</td>
<td>cube_enlarge('(1,2), (3,4)', 0.5, 3) → (0.5, 1.5, -0.5), (3.5, 4.5, 0.5)</td>
</tr>
</tbody>
</table>

F.9.4. Defaults

I believe this union:
select cube_union('(0,5,2),(2,3,1)', '0');
cube_union
-------------------
(0, 0, 0),(2, 5, 2)
(1 row)

does not contradict common sense, neither does the intersection

select cube_inter('(0,-1),(1,1)', '(-2),(2)');
cube_inter
-------------
(0, 0),(1, 0)
(1 row)

In all binary operations on differently-dimensioned cubes, I assume the lower-dimensional one to be a Cartesian projection, i.e., having zeroes in place of coordinates omitted in the string representation. The above examples are equivalent to:

cube_union('(0,5,2),(2,3,1)','(0,0,0),(0,0,0)');
cube_inter('(0,-1),(1,1)','(-2,0),(2,0)');

The following containment predicate uses the point syntax, while in fact the second argument is internally represented by a box. This syntax makes it unnecessary to define a separate point type and functions for (box,point) predicates.

select cube_contains('(0,0),(1,1)', '0.5,0.5');
cube_contains
--------------
t
(1 row)

F.9.5. Notes

For examples of usage, see the regression test sql/cube.sql.

To make it harder for people to break things, there is a limit of 100 on the number of dimensions of cubes. This is set in cubedata.h if you need something bigger.

F.9.6. Credits

Original author: Gene Selkov, Jr. <selkovjr@mcs.anl.gov>, Mathematics and Computer Science Division, Argonne National Laboratory.

My thanks are primarily to Prof. Joe Hellerstein (https://dsf.berkeley.edu/jmh/) for elucidating the gist of the GiST (http://gist.cs.berkeley.edu/), and to his former student Andy Dong for his example written for Illustra. I am also grateful to all Postgres developers, present and past, for enabling myself to create my own world and live undisturbed in it. And I would like to acknowledge my gratitude to Argonne Lab and to the U.S. Department of Energy for the years of faithful support of my database research.

Minor updates to this package were made by Bruno Wolff III <bruno@wolff.to> in August/September of 2002. These include changing the precision from single precision to double precision and adding some new functions.

Additional updates were made by Joshua Reich <josh@root.net> in July 2006. These include cube(float8[], float8[]) and cleaning up the code to use the V1 call protocol instead of the deprecated V0 protocol.

F.10. dblink

dblink is a module that supports connections to other Postgres Pro databases from within a database session.
See also `postgres_fdw`, which provides roughly the same functionality using a more modern and standards-compliant infrastructure.
**dblink_connect**

dblink_connect — opens a persistent connection to a remote database

**Synopsis**

dblink_connect(text connstr) returns text  
dblink_connect(text connname, text connstr) returns text

**Description**

dblink_connect() establishes a connection to a remote Postgres Pro database. The server and database to be contacted are identified through a standard libpq connection string. Optionally, a name can be assigned to the connection. Multiple named connections can be open at once, but only one unnamed connection is permitted at a time. The connection will persist until closed or until the database session is ended.

The connection string may also be the name of an existing foreign server. It is recommended to use the foreign-data wrapper dblink_fdw when defining the foreign server. See the example below, as well as CREATE SERVER and CREATE USER MAPPING.

**Arguments**

*conname*

The name to use for this connection; if omitted, an unnamed connection is opened, replacing any existing unnamed connection.

*connstr*

libpq-style connection info string, for example hostaddr=127.0.0.1 port=5432 dbname=mydb user=postgres password=mypasswd options=-csearch_path=. For details see Section 32.1.1. Alternatively, the name of a foreign server.

**Return Value**

Returns status, which is always OK (since any error causes the function to throw an error instead of returning).

**Notes**

If untrusted users have access to a database that has not adopted a secure schema usage pattern, begin each session by removing publicly-writable schemas from search_path. One could, for example, add options=-csearch_path= to connstr. This consideration is not specific to dblink; it applies to every interface for executing arbitrary SQL commands.

Only superusers may use dblink_connect to create non-password-authenticated connections. If non-superusers need this capability, use dblink_connect_u instead.

It is unwise to choose connection names that contain equal signs, as this opens a risk of confusion with connection info strings in other dblink functions.

**Examples**

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
   dblink_connect
----------------
       OK
(1 row)

SELECT dblink_connect('myconn', 'dbname=postgres options=-csearch_path=');
```

2260
Additional Supplied Modules

```
dblink_connect
-------------
OK
(1 row)

-- FOREIGN DATA WRAPPER functionality
-- Note: local connection must require password authentication for this to work properly
-- Otherwise, you will receive the following error from dblink_connect():
-- ERROR: password is required
-- DETAIL: Non-superuser cannot connect if the server does not request a password.
-- HINT: Target server's authentication method must be changed.

CREATE SERVER fdtest FOREIGN DATA WRAPPER dblink_fdw OPTIONS (hostaddr '127.0.0.1', dbname 'contrib_regression');
CREATE USER regress_dblink_user WITH PASSWORD 'secret';
CREATE USER MAPPING FOR regress_dblink_user SERVER fdtest OPTIONS (user 'regress_dblink_user', password 'secret');
GRANT USAGE ON FOREIGN SERVER fdtest TO regress_dblink_user;
GRANT SELECT ON TABLE foo TO regress_dblink_user;

\set ORIGINAL_USER :USER
\c - regress_dblink_user
SELECT dblink_connect('myconn', 'fdtest');
dblink_connect
-------------
OK
(1 row)

SELECT * FROM dblink('myconn', 'SELECT * FROM foo') AS t(a int, b text, c text[]);

REVOKE SELECT ON TABLE foo FROM regress_dblink_user;
DROP USER MAPPING FOR regress_dblink_user SERVER fdtest;
DROP USER regress_dblink_user;
DROP SERVER fdtest;
```
**dblink_connect_u**

*dblink_connect_u* — opens a persistent connection to a remote database, insecurely

**Synopsis**

```
dblink_connect_u(text connstr) returns text
```
```
dblink_connect_u(text connname, text connstr) returns text
```

**Description**

*dblink_connect_u()* is identical to *dblink_connect()*, except that it will allow non-superusers to connect using any authentication method.

If the remote server selects an authentication method that does not involve a password, then impersonation and subsequent escalation of privileges can occur, because the session will appear to have originated from the user as which the local Postgres Pro server runs. Also, even if the remote server does demand a password, it is possible for the password to be supplied from the server environment, such as a `~/.pgpass` file belonging to the server's user. This opens not only a risk of impersonation, but the possibility of exposing a password to an untrustworthy remote server. Therefore, *dblink_connect_u()* is initially installed with all privileges revoked from `PUBLIC`, making it un-callable except by superusers. In some situations it may be appropriate to grant `EXECUTE` permission for *dblink_connect_u()* to specific users who are considered trustworthy, but this should be done with care. It is also recommended that any `~/.pgpass` file belonging to the server’s user not contain any records specifying a wildcard host name.

For further details see *dblink_connect()*.
**dblink_disconnect**

`dblink_disconnect` — closes a persistent connection to a remote database

**Synopsis**

`dblink_disconnect()` returns text

`dblink_disconnect(text conname) returns text`

**Description**

`dblink_disconnect()` closes a connection previously opened by `dblink_connect()`. The form with no arguments closes an unnamed connection.

**Arguments**

`conname`

The name of a named connection to be closed.

**Return Value**

Returns status, which is always `OK` (since any error causes the function to throw an error instead of returning).

**Examples**

```
SELECT dblink_disconnect();
  dblink_disconnect
--------------
   OK
(1 row)

SELECT dblink_disconnect('myconn');
  dblink_disconnect
--------------
   OK
(1 row)
```
**dblink**

```
dblink — executes a query in a remote database
```

**Synopsis**

```
dblink(text connname, text sql [, bool fail_on_error]) returns setof record
dblink(text connstr, text sql [, bool fail_on_error]) returns setof record
dblink(text sql [, bool fail_on_error]) returns setof record
```

**Description**

`dblink` executes a query (usually a `SELECT`, but it can be any SQL statement that returns rows) in a remote database.

When two `text` arguments are given, the first one is first looked up as a persistent connection’s name; if found, the command is executed on that connection. If not found, the first argument is treated as a connection info string as for `dblink_connect`, and the indicated connection is made just for the duration of this command.

**Arguments**

- **connname**
  Name of the connection to use; omit this parameter to use the unnamed connection.

- **connstr**
  A connection info string, as previously described for `dblink_connect`.

- **sql**
  The SQL query that you wish to execute in the remote database, for example `select * from foo`.

- **fail_on_error**
  If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function returns no rows.

**Return Value**

The function returns the row(s) produced by the query. Since `dblink` can be used with any query, it is declared to return `record`, rather than specifying any particular set of columns. This means that you must specify the expected set of columns in the calling query — otherwise Postgres Pro would not know what to expect. Here is an example:

```
SELECT *
FROM dblink('dbname=mydb options=-csearch_path=',
    'select proname, prosrc from pg_proc')
AS t1(proname name, prosrc text)
WHERE proname LIKE 'bytea%';
```

The “alias” part of the `FROM` clause must specify the column names and types that the function will return. (Specifying column names in an alias is actually standard SQL syntax, but specifying column types is a Postgres Pro extension.) This allows the system to understand what `*` should expand to, and what `proname` in the `WHERE` clause refers to, in advance of trying to execute the function. At run time, an error will be thrown if the actual query result from the remote database does not have the same number of columns shown in the `FROM` clause. The column names need not match, however, and `dblink` does not insist on exact type matches either. It will succeed so long as the returned data strings are valid input for the column type declared in the `FROM` clause.

2264
Notes

A convenient way to use `dblink` with predetermined queries is to create a view. This allows the column type information to be buried in the view, instead of having to spell it out in every query. For example,

```sql
CREATE VIEW myremote_pg_proc AS
    SELECT *
    FROM dblink('dbname=postgres options=-csearch_path=','select proname, prosrc from pg_proc')
    AS t1(proname name, prosrc text);

SELECT * FROM myremote_pg_proc WHERE proname LIKE 'bytea%';
```

Examples

```
SELECT * FROM dblink('dbname=postgres options=-csearch_path=','select proname, prosrc from pg_proc')
    AS t1(proname name, prosrc text) WHERE proname LIKE 'bytea%';
```

```
proname   |   prosrc
------------+------------

  byteaout |  byteaout
  (14 rows)
**dblink_exec**

*dblink_exec* — executes a command in a remote database

**Synopsis**

dblink_exec(text connname, text sql [, bool fail_on_error]) returns text
dblink_exec(text connstr, text sql [, bool fail_on_error]) returns text
dblink_exec(text sql [, bool fail_on_error]) returns text

**Description**

dblink_exec executes a command (that is, any SQL statement that doesn't return rows) in a remote database.

When two text arguments are given, the first one is first looked up as a persistent connection's name; if found, the command is executed on that connection. If not found, the first argument is treated as a connection info string as for dblink_connect, and the indicated connection is made just for the duration of this command.

**Arguments**

*connname*

Name of the connection to use; omit this parameter to use the unnamed connection.

*connstr*

A connection info string, as previously described for dblink_connect.

*sql*

The SQL command that you wish to execute in the remote database, for example *insert into foo values(0, 'a', '{"a0","b0","c0"}')*.

*fail_on_error*

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function's return value is set to ERROR.

**Return Value**

Returns status, either the command's status string or ERROR.

**Examples**

```
SELECT dblink_connect('dbname=dblink_test_standby');
  dblink_connect
-------------------
  OK
  (1 row)

SELECT dblink_exec('insert into foo values(21, ''z'', ''{"a0","b0","c0"}'''));
  dblink_exec
-----------------------
  INSERT 943366 1
  (1 row)

SELECT dblink_connect('myconn', 'dbname=regression');
  dblink_connect
```

2267
SELECT dblink_exec('myconn', 'insert into foo values(21, ''z'',
''{"a0","b0","c0"}'''););
  
SELECT dblink_exec('myconn', 'insert into pg_class values (''foo'')',false);
NOTICE: sql error
DETAIL:  ERROR:  null value in column "relnamespace" violates not-null constraint

SELECT dblink_exec('myconn', 'insert into pg_class values (''foo'')',false);
NOTICE: sql error
DETAIL:  ERROR:  null value in column "relnamespace" violates not-null constraint
Additional Supplied Modules

**dblink_open**

*dblink_open* — opens a cursor in a remote database

**Synopsis**

```c
dblink_open(text cursorname, text sql [, bool fail_on_error]) returns text
dblink_open(text connname, text cursorname, text sql [, bool fail_on_error]) returns text
```

**Description**

*dblink_open()* opens a cursor in a remote database. The cursor can subsequently be manipulated with *dblink_fetch()* and *dblink_close()*.

**Arguments**

- **connname**
  Name of the connection to use; omit this parameter to use the unnamed connection.

- **cursorname**
  The name to assign to this cursor.

- **sql**
  The *SELECT* statement that you wish to execute in the remote database, for example *select * from pg_class*.

- **fail_on_error**
  If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function's return value is set to *ERROR*.

**Return Value**

Returns status, either *OK* or *ERROR*.

**Notes**

Since a cursor can only persist within a transaction, *dblink_open* starts an explicit transaction block (*BEGIN*) on the remote side, if the remote side was not already within a transaction. This transaction will be closed again when the matching *dblink_close* is executed. Note that if you use *dblink_exec* to change data between *dblink_open* and *dblink_close*, and then an error occurs or you use *dblink_disconnect* before *dblink_close*, your change *will be lost* because the transaction will be aborted.

**Examples**

```sql
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
  dblink_connect
----------------
  OK
  (1 row)

SELECT dblink_open('foo', 'select proname, prosrc from pg_proc');
  dblink_open
-------------
  OK
```
| (1 row) |
**dblink_fetch**

`dblink_fetch` — returns rows from an open cursor in a remote database

**Synopsis**

```sql
dblink_fetch(text cursorname, int howmany [, bool fail_on_error]) returns setof record
dblink_fetch(text connname, text cursorname, int howmany [, bool fail_on_error])
returns setof record
```

**Description**

`dblink_fetch` fetches rows from a cursor previously established by `dblink_open`.

**Arguments**

- **connname**
  Name of the connection to use; omit this parameter to use the unnamed connection.

- **cursorname**
  The name of the cursor to fetch from.

- **howmany**
  The maximum number of rows to retrieve. The next `howmany` rows are fetched, starting at the current cursor position, moving forward. Once the cursor has reached its end, no more rows are produced.

- **fail_on_error**
  If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function returns no rows.

**Return Value**

The function returns the row(s) fetched from the cursor. To use this function, you will need to specify the expected set of columns, as previously discussed for `dblink`.

**Notes**

On a mismatch between the number of return columns specified in the `FROM` clause, and the actual number of columns returned by the remote cursor, an error will be thrown. In this event, the remote cursor is still advanced by as many rows as it would have been if the error had not occurred. The same is true for any other error occurring in the local query after the remote `FETCH` has been done.

**Examples**

```sql
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
  dblink_connect
----------------
  OK
(1 row)

SELECT dblink_open('foo', 'select proname, prosrc from pg_proc where proname like ''bytea%''');
  dblink_open
-------------
  OK
(1 row)
```
### Additional Supplied Modules

```sql
SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source text);
  funcname | source
-------------
 byteacat | byteacat
 byteacmp | byteacmp
 byteaeq  | byteaeq
 byteage  | byteage
 byteagt  | byteagt
 (5 rows)
```

```sql
SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source text);
  funcname | source
-------------
 byteain  | byteain
 byteale  | byteale
 bytealike| bytealike
 bytealt  | bytealt
 byteane  | byteane
 (5 rows)
```

```sql
SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source text);
  funcname | source
-------------
 byteanlike| byteanlike
 byteaout  | byteaout
 (2 rows)
```

```sql
SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source text);
  funcname | source
-------------
 (0 rows)
```
Additional Supplied Modules

\textbf{dblink\_close}

dblink\_close — closes a cursor in a remote database

\textbf{Synopsis}

dblink\_close(text cursorname [, bool fail\_on\_error]) returns text
dblink\_close(text connname, text cursorname [, bool fail\_on\_error]) returns text

\textbf{Description}

dblink\_close closes a cursor previously opened with dblink\_open.

\textbf{Arguments}

\textit{connname}

Name of the connection to use; omit this parameter to use the unnamed connection.

\textit{cursorname}

The name of the cursor to close.

\textit{fail\_on\_error}

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function's return value is set to ERROR.

\textbf{Return Value}

Returns status, either \texttt{OK} or \texttt{ERROR}.

\textbf{Notes}

If dblink\_open started an explicit transaction block, and this is the last remaining open cursor in this connection, dblink\_close will issue the matching COMMIT.

\textbf{Examples}

```
SELECT dblink\_connect('dbname=postgres options=-csearch\_path=');
   dblink\_connect
--------------
  OK
   (1 row)

SELECT dblink\_open('foo', 'select proname, prosrc from pg\_proc');
   dblink\_open
--------------
  OK
   (1 row)

SELECT dblink\_close('foo');
   dblink\_close
--------------
  OK
   (1 row)
```
**dblink_get_connections**

`dblink_get_connections()` returns the names of all open named dblink connections

**Synopsis**

`dblink_get_connections()` returns text[]

**Description**

`dblink_get_connections` returns an array of the names of all open named dblink connections.

**Return Value**

Returns a text array of connection names, or NULL if none.

**Examples**

```
SELECT dblink_get_connections();
```
**dblink_error_message**

`dblink_error_message` — gets last error message on the named connection

**Synopsis**

`dblink_error_message(text connname) returns text`

**Description**

`dblink_error_message` fetches the most recent remote error message for a given connection.

**Arguments**

`connname`  
Name of the connection to use.

**Return Value**

Returns last error message, or `OK` if there has been no error in this connection.

**Notes**

When asynchronous queries are initiated by `dblink_send_query`, the error message associated with the connection might not get updated until the server's response message is consumed. This typically means that `dblink_is_busy` or `dblink_get_result` should be called prior to `dblink_error_message`, so that any error generated by the asynchronous query will be visible.

**Examples**

```sql
SELECT dblink_error_message('dtest1');
```
Additional Supplied Modules

**dblink_send_query**

dblink_send_query — sends an async query to a remote database

**Synopsis**

dblink_send_query(text connname, text sql) returns int

**Description**

dblink_send_query sends a query to be executed asynchronously, that is, without immediately waiting for the result. There must not be an async query already in progress on the connection.

After successfully dispatching an async query, completion status can be checked with dblink_is_busy, and the results are ultimately collected with dblink_get_result. It is also possible to attempt to cancel an active async query using dblink_cancel_query.

**Arguments**

- **connname**
  
  Name of the connection to use.

- **sql**
  
  The SQL statement that you wish to execute in the remote database, for example select * from pg_class.

**Return Value**

Returns 1 if the query was successfully dispatched, 0 otherwise.

**Examples**

SELECT dblink_send_query('dtest1', 'SELECT * FROM foo WHERE f1 < 3');
**dblink_is_busy**

dblink_is_busy — checks if connection is busy with an async query

**Synopsis**

dblink_is_busy(text conname) returns int

**Description**

dblink_is_busy tests whether an async query is in progress.

**Arguments**

`conname`

Name of the connection to check.

**Return Value**

Returns 1 if connection is busy, 0 if it is not busy. If this function returns 0, it is guaranteed that dblink_get_result will not block.

**Examples**

SELECT dblink_is_busy('dtest1');
**dblink_get_notify**

*dblink_get_notify* — retrieve async notifications on a connection

**Synopsis**

```plaintext
dblink_get_notify() returns setof (notify_name text, be_pid int, extra text)
dblink_get_notify(text connname) returns setof (notify_name text, be_pid int, extra text)
```

**Description**

*dblink_get_notify* retrieves notifications on either the unnamed connection, or on a named connection if specified. To receive notifications via dblink, LISTEN must first be issued, using dblink_exec. For details see LISTEN and NOTIFY.

**Arguments**

*connname*

The name of a named connection to get notifications on.

**Return Value**

Returns setof (notify_name text, be_pid int, extra text), or an empty set if none.

**Examples**

```plaintext
SELECT dblink_exec('LISTEN virtual');
  dblink_exec
    ---------------------
    LISTEN
(1 row)

SELECT * FROM dblink_get_notify();
  notify_name | be_pid | extra
  -----------+--------+-------
(0 rows)

NOTIFY virtual;

**dblink_get_result**

*dblink_get_result* — gets an async query result

**Synopsis**

`dblink_get_result(text connname [, bool fail_on_error]) returns setof record`

**Description**

`dblink_get_result` collects the results of an asynchronous query previously sent with `dblink_send_query`. If the query is not already completed, `dblink_get_result` will wait until it is.

**Arguments**

- **connname**
  
  Name of the connection to use.

- **fail_on_error**

  If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function returns no rows.

**Return Value**

For an async query (that is, an SQL statement returning rows), the function returns the row(s) produced by the query. To use this function, you will need to specify the expected set of columns, as previously discussed for `dblink`.

For an async command (that is, an SQL statement not returning rows), the function returns a single row with a single text column containing the command's status string. It is still necessary to specify that the result will have a single text column in the calling `FROM` clause.

**Notes**

This function *must* be called if `dblink_send_query` returned 1. It must be called once for each query sent, and one additional time to obtain an empty set result, before the connection can be used again.

When using `dblink_send_query` and `dblink_get_result`, `dblink` fetches the entire remote query result before returning any of it to the local query processor. If the query returns a large number of rows, this can result in transient memory bloat in the local session. It may be better to open such a query as a cursor with `dblink_open` and then fetch a manageable number of rows at a time. Alternatively, use plain `dblink()`, which avoids memory bloat by spooling large result sets to disk.

**Examples**

```sql
contrib_regression=# SELECT dblink_connect('dtest1', 'dbname=contrib_regression');
     dblink_connect
----------------
        OK
(1 row)

contrib_regression=# SELECT * FROM contrib_regression-
contrib_regression-# dblink_send_query('dtest1', 'select * from foo where f1 < 3') AS t1;

   t1
----
1
(1 row)
```
contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text, f3 text[]);
  f1 | f2 |     f3
-----+----+------------
  0 | a  | {a0,b0,c0}
  1 | b  | {a1,b1,c1}
  2 | c  | {a2,b2,c2}
(3 rows)

contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text, f3 text[]);
  f1 | f2 |     f3
-----+----+------------
  7 | h  | {a7,b7,c7}
  8 | i  | {a8,b8,c8}
  9 | j  | {a9,b9,c9}
 10 | k  | {a10,b10,c10}
(4 rows)

contrib_regression=# SELECT * FROM dblink_send_query('dtest1', 'select * from foo where f1 < 3; select * from foo where f1 > 6') AS t1;
  t1
----
  1
(1 row)

contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text, f3 text[]);
  f1 | f2 |     f3
-----+----+------------
  7 | h  | {a7,b7,c7}
  8 | i  | {a8,b8,c8}
  9 | j  | {a9,b9,c9}
 10 | k  | {a10,b10,c10}
(4 rows)
**dblink_cancel_query**

`dblink_cancel_query` — cancels any active query on the named connection

**Synopsis**

```
    dblink_cancel_query(text connname) returns text
```

**Description**

`dblink_cancel_query` attempts to cancel any query that is in progress on the named connection. Note that this is not certain to succeed (since, for example, the remote query might already have finished). A cancel request simply improves the odds that the query will fail soon. You must still complete the normal query protocol, for example by calling `dblink_get_result`.

**Arguments**

`connname`

Name of the connection to use.

**Return Value**

Returns `OK` if the cancel request has been sent, or the text of an error message on failure.

**Examples**

```
SELECT dblink_cancel_query('dtest1');
```
Additional Supplied Modules

**dblink_get_pkey**

*dblink_get_pkey* — returns the positions and field names of a relation's primary key fields

**Synopsis**

```
dblink_get_pkey(text relname) returns setof dblink_pkey_results
```

**Description**

*dblink_get_pkey* provides information about the primary key of a relation in the local database. This is sometimes useful in generating queries to be sent to remote databases.

**Arguments**

relname

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example "FooBar"; without quotes, the string will be folded to lower case.

**Return Value**

Returns one row for each primary key field, or no rows if the relation has no primary key. The result row type is defined as

```
CREATE TYPE dblink_pkey_results AS (position int, colname text);
```

The `position` column simply runs from 1 to `N`; it is the number of the field within the primary key, not the number within the table's columns.

**Examples**

```
CREATE TABLE foobar (    f1 int,    f2 int,    f3 int,        PRIMARY KEY (f1, f2, f3) );
CREATE TABLE

SELECT * FROM dblink_get_pkey('foobar');

<table>
<thead>
<tr>
<th>position</th>
<th>colname</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>f1</td>
</tr>
<tr>
<td>2</td>
<td>f2</td>
</tr>
<tr>
<td>3</td>
<td>f3</td>
</tr>
</tbody>
</table>

(3 rows)
```
**dblink_build_sql_insert**

dblink_build_sql_insert — builds an INSERT statement using a local tuple, replacing the primary key field values with alternative supplied values

**Synopsis**

dblink_build_sql_insert(text relname,
                        int2vector primary_key_attnums,
                        integer num_primary_key_atts,
                        text[] src_pk_att_vals_array,
                        text[] tgt_pk_att_vals_array) returns text

**Description**

dblink_build_sql_insert can be useful in doing selective replication of a local table to a remote database. It selects a row from the local table based on primary key, and then builds an SQL INSERT command that will duplicate that row, but with the primary key values replaced by the values in the last argument. (To make an exact copy of the row, just specify the same values for the last two arguments.)

**Arguments**

* relname
  
  Name of a local relation, for example foo or myschema.mytab. Include double quotes if the name is mixed-case or contains special characters, for example "FooBar"; without quotes, the string will be folded to lower case.

* primary_key_attnums
  
  Attribute numbers (1-based) of the primary key fields, for example 1 2.

* num_primary_key_atts
  
  The number of primary key fields.

* src_pk_att_vals_array
  
  Values of the primary key fields to be used to look up the local tuple. Each field is represented in text form. An error is thrown if there is no local row with these primary key values.

* tgt_pk_att_vals_array
  
  Values of the primary key fields to be placed in the resulting INSERT command. Each field is represented in text form.

**Return Value**

Returns the requested SQL statement as text.

**Notes**

As of PostgreSQL 9.0, the attribute numbers in primary_key_attnums are interpreted as logical column numbers, corresponding to the column's position in SELECT * FROM relname. Previous versions interpreted the numbers as physical column positions. There is a difference if any column(s) to the left of the indicated column have been dropped during the lifetime of the table.

**Examples**

SELECT dblink_build_sql_insert('foo', '1 2', 2, '{"1", "a"}', '{"1", "b''a"}');

```sql
  dblink_build_sql_insert
--------------------------------------------------
2283
```
INSERT INTO foo(f1,f2,f3) VALUES('1', 'b''a', '1')
(1 row)
**dblink_build_sql_delete**

**dblink_build_sql_delete** — builds a DELETE statement using supplied values for primary key field values

### Synopsis

```sql
dblink_build_sql_delete(text relname,
                       int2vector primary_key_attnums,
                       integer num_primary_key_atts,
                       text[] tgt_pk_att_vals_array) returns text
```

### Description

`dblink_build_sql_delete` can be useful in doing selective replication of a local table to a remote database. It builds an SQL `DELETE` command that will delete the row with the given primary key values.

### Arguments

- **relname**
  Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example "FooBar"; without quotes, the string will be folded to lower case.

- **primary_key_attnums**
  Attribute numbers (1-based) of the primary key fields, for example 1 2.

- **num_primary_key_atts**
  The number of primary key fields.

- **tgt_pk_att_vals_array**
  Values of the primary key fields to be used in the resulting `DELETE` command. Each field is represented in text form.

### Return Value

Returns the requested SQL statement as text.

### Notes

As of PostgreSQL 9.0, the attribute numbers in `primary_key_attnums` are interpreted as logical column numbers, corresponding to the column's position in `SELECT * FROM relname`. Previous versions interpreted the numbers as physical column positions. There is a difference if any column(s) to the left of the indicated column have been dropped during the lifetime of the table.

### Examples

```sql
SELECT dblink_build_sql_delete('"MyFoo"', '1 2', 2, {'"i"', 'b'});
```

```
DELETE FROM "MyFoo" WHERE f1='1' AND f2='b'
(1 row)
```
**dblink_build_sql_update**

dblink_build_sql_update — builds an UPDATE statement using a local tuple, replacing the primary key field values with alternative supplied values

**Synopsis**

dblink_build_sql_update(text relname,
int2vector primary_key_attnums,
integer num_primary_key_atts,
text[] src_pk_att_vals_array,
text[] tgt_pk_att_vals_array) returns text

**Description**
dblink_build_sql_update can be useful in doing selective replication of a local table to a remote database. It selects a row from the local table based on primary key, and then builds an SQL UPDATE command that will duplicate that row, but with the primary key values replaced by the values in the last argument. (To make an exact copy of the row, just specify the same values for the last two arguments.) The UPDATE command always assigns all fields of the row — the main difference between this and dblink_build_sql_insert is that it's assumed that the target row already exists in the remote table.

**Arguments**

* relname
  Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example "FooBar"; without quotes, the string will be folded to lower case.

* primary_key_attnums
  Attribute numbers (1-based) of the primary key fields, for example `1 2`.

* num_primary_key_atts
  The number of primary key fields.

* src_pk_att_vals_array
  Values of the primary key fields to be used to look up the local tuple. Each field is represented in text form. An error is thrown if there is no local row with these primary key values.

* tgt_pk_att_vals_array
  Values of the primary key fields to be placed in the resulting UPDATE command. Each field is represented in text form.

**Return Value**

Returns the requested SQL statement as text.

**Notes**

As of PostgreSQL 9.0, the attribute numbers in primary_key_attnums are interpreted as logical column numbers, corresponding to the column's position in SELECT * FROM relname. Previous versions interpreted the numbers as physical column positions. There is a difference if any column(s) to the left of the indicated column have been dropped during the lifetime of the table.

**Examples**

```sql
SELECT dblink_build_sql_update('foo', '1 2', 2, '{"1", "a"}', '{"1", "b"}');
```
F.11. dict_int

dict_int is an example of an add-on dictionary template for full-text search. The motivation for this example dictionary is to control the indexing of integers (signed and unsigned), allowing such numbers to be indexed while preventing excessive growth in the number of unique words, which greatly affects the performance of searching.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.11.1. Configuration

The dictionary accepts three options:

- The `maxlen` parameter specifies the maximum number of digits allowed in an integer word. The default value is 6.
- The `rejectlong` parameter specifies whether an overlength integer should be truncated or ignored. If `rejectlong` is false (the default), the dictionary returns the first `maxlen` digits of the integer. If `rejectlong` is true, the dictionary treats an overlength integer as a stop word, so that it will not be indexed. Note that this also means that such an integer cannot be searched for.
- The `absval` parameter specifies whether leading "+" or "-" signs should be removed from integer words. The default is false. When true, the sign is removed before `maxlen` is applied.

F.11.2. Usage

Installing the dict_int extension creates a text search template `intdict_template` and a dictionary `intdict` based on it, with the default parameters. You can alter the parameters, for example:

```sql
mydb# ALTER TEXT SEARCH DICTIONARY intdict (MAXLEN = 4, REJECTLONG = true);
```

or create new dictionaries based on the template.

To test the dictionary, you can try:

```sql
mydb# select ts_lexize('intdict', '12345678');
```

but real-world usage will involve including it in a text search configuration as described in Chapter 12. That might look like this:

```sql
ALTER TEXT SEARCH CONFIGURATION english
  ALTER MAPPING FOR int, uint WITH intdict;
```

F.12. dict_xsyn

dict_xsyn (Extended Synonym Dictionary) is an example of an add-on dictionary template for full-text search. This dictionary type replaces words with groups of their synonyms, and so makes it possible to search for a word using any of its synonyms.

F.12.1. Configuration

A dict_xsyn dictionary accepts the following options:

- `matchorig` controls whether the original word is accepted by the dictionary. Default is true.
- `matchsynonyms` controls whether the synonyms are accepted by the dictionary. Default is false.
- `keeporig` controls whether the original word is included in the dictionary's output. Default is true.
• **keepsynonyms** controls whether the synonyms are included in the dictionary's output. Default is true.

• **rules** is the base name of the file containing the list of synonyms. This file must be stored in
  `$SHAREDIR/tsearch_data/` (where `$SHAREDIR` means the Postgres Pro installation's shared-data directory). Its name must end in `.rules` (which is not to be included in the `rules` parameter).

The rules file has the following format:

• Each line represents a group of synonyms for a single word, which is given first on the line. Synonyms are separated by whitespace, thus:
  
  word syn1 syn2 syn3

• The sharp (`#`) sign is a comment delimiter. It may appear at any position in a line. The rest of the line will be skipped.

Look at `xsyn_sample.rules`, which is installed in `$SHAREDIR/tsearch_data/`, for an example.

### F.12.2. Usage

Installing the `dict_xsyn` extension creates a text search template `xsyn_template` and a dictionary `xsyn` based on it, with default parameters. You can alter the parameters, for example

```sql
mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=false);
```

or create new dictionaries based on the template.

To test the dictionary, you can try

```sql
mydb=# SELECT ts_lexize('xsyn', 'word');
  
  ts_lexize
  -----------------------
  {syn1,syn2,syn3}

mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=true);

mydb=# SELECT ts_lexize('xsyn', 'word');
  
  ts_lexize
  -----------------------
  {word,syn1,syn2,syn3}

mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=false, MATCHSYNONYMS=true);

mydb=# SELECT ts_lexize('xsyn', 'syn1');
  
  ts_lexize
  -----------------------
  {syn1,syn2,syn3}

mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=true, MATCHORIG=false, KEEPSYNONYMS=false);

mydb=# SELECT ts_lexize('xsyn', 'syn1');
  
  ts_lexize
  -----------------------
  {word}
```

Real-world usage will involve including it in a text search configuration as described in Chapter 12. That might look like this:
ALTER TEXT SEARCH CONFIGURATION english
ALTER MAPPING FOR word, asciword WITH xsyn, english_stem;

F.13. dump_stat
The dump_stat module provides functions that allow you to backup and recover the contents of the pg_statistic table. When performing a dump/restore, you can use dump_stat to migrate the original statistics to the new server instead of running the ANALYZE command for the whole database cluster, which can significantly reduce downtime for large databases. The dump_statistic function generates INSERT statements which can later be applied to a compatible database. To successfully restore statistical data, you must install the extension on both the original and the recipient servers since these statements rely on the provided dump_stat functions.

Note that the definition of the pg_statistic table might change occasionally, which means that generated dump might be incompatible with future releases of Postgres Pro.

F.13.1. Installation
The dump_stat extension is included into Postgres Pro. Once you have Postgres Pro installed, you must execute the CREATE EXTENSION command to enable dump_stat, as follows:
CREATE EXTENSION dump_stat;

F.13.2. Functions

anyarray_to_text(array anyarray) returns text

Returns the given array as text.

dump_statistic() returns setof text
dump_statistic() dumps the contents of the pg_statistic system catalog. It produces an INSERT statement per each tuple of the pg_statistic, excluding the ones that contain statistical data for tables in the information_schema and pg_catalog schemas.

The INSERT statement takes form of

WITH upsert as (    UPDATE pg_catalog.pg_statistic SET column_name = expression [, ...] WHERE starelid = t_relnam::regclass AND to_attnam(t_relnam, staattnum) = t_attname AND to_atttype(t_relnam, staattnum) = t_atttype AND stainherit = t_stainherit RETURNING *)
    ins as ( SELECT expression [, ...] WHERE NOT EXISTS (SELECT * FROM upsert) AND to_attnam(t_relnam, t_attname) IS NOT NULL AND to_atttype(t_relnam, t_attname) = t_atttype
    INSERT INTO pg_catalog.pg_statistic SELECT * FROM ins;

where expression can be one of:

array_in(array_text, type_name::regtype::oid, -1)
value::type_name

To save the produced statements, redirect the psql output into a file using standard psql options. For details on the available psql options, see psql. Meta-commands starting with a backslash are not supported.

For example, to save statistics for the dbname database into a dump_stat.sql file, run:

$ psql -XAtq -c "SELECT dump_statistic()" dbname > dump_stat.sql

2289
dump_statistic(schema_name text) returns setof text

dump_statistic dumps the contents of the pg_statistic system catalog. It produces an INSERT statement per each tuple of the pg_statistic that relates to some table in the schema_name schema.

dump_statistic(schema_name text, table_name text) returns setof text

dump_statistic dumps the contents of the pg_statistic system catalog. It produces an INSERT statement per each tuple of the pg_statistic that relates to the specified schema_name.table_name table.

dump_statistic(relation regclass) returns setof text

dump_statistic dumps the contents of the pg_statistic system catalog. It produces an INSERT statement per each tuple of the pg_statistic that contains statistical data for the specified relation.

to_schema_qualified_operator(opid oid) returns text

Fetches the schema-qualified operator name by operator id opid. For example:

test=# SELECT to_schema_qualified_operator('+(int,int)'::regoperator);
to_schema_qualified_operator
------------------------------------------------
pg_catalog.+(pg_catalog.int4, pg_catalog.int4)
(1 row)
to_schema_qualified_type(typid oid) returns text

Fetches the schema-qualified type name by type id typid.

to_schema_qualified_relation(relid oid) returns text

Fetches the schema-qualified relation name by relation id relid.

anyarrayElemtype(arr anyarray) returns oid

Returns the element type of the given array as oid. For example:

test=# SELECT anyarrayElemtype(array_in('{1,2,3}', 'int'::regtype, -1));
anyarrayElemtype
-------------------
23
(1 row)
to_attname(relation regclass, colnum int2) returns text

Given a relation name relation and a column number colnum, returns the column name as text.

to_attnum(relation regclass, col text) returns int2

Given a relation name relation and a column name col, returns the column number as int2.

to_atttype(relation regclass, col text) returns text

Given a relation name relation and a column name col, returns the schema-qualified column type as text.

to_atttype(relation regclass, colnum int2) returns text

Given a relation name relation and a column number colnum, returns the schema-qualified column type as text.

to_namespace(nsp text) returns oid

to_namespace duplicates the behavior of the cast to the regnamespace type, which is not present in the PostgreSQL 9.4 release (and prior releases). This function returns the oid of the given schema.
get_namespace(relation oid) returns oid

get_namespace returns the schema of the given relation as oid.

F.14. earthdistance

The earthdistance module provides two different approaches to calculating great circle distances on the surface of the Earth. The one described first depends on the cube module. The second one is based on the built-in point data type, using longitude and latitude for the coordinates.

In this module, the Earth is assumed to be perfectly spherical. (If that’s too inaccurate for you, you might want to look at the PostGIS project.)

The cube module must be installed before earthdistance can be installed (although you can use the CASCADE option of CREATE EXTENSION to install both in one command).

Caution

It is strongly recommended that earthdistance and cube be installed in the same schema, and that that schema be one for which CREATE privilege has not been and will not be granted to any untrusted users. Otherwise there are installation-time security hazards if earthdistance's schema contains objects defined by a hostile user. Furthermore, when using earthdistance's functions after installation, the entire search path should contain only trusted schemas.

F.14.1. Cube-Based Earth Distances

Data is stored in cubes that are points (both corners are the same) using 3 coordinates representing the x, y, and z distance from the center of the Earth. A domain earth over cube is provided, which includes constraint checks that the value meets these restrictions and is reasonably close to the actual surface of the Earth.

The radius of the Earth is obtained from the earth() function. It is given in meters. But by changing this one function you can change the module to use some other units, or to use a different value of the radius that you feel is more appropriate.

This package has applications to astronomical databases as well. Astronomers will probably want to change earth() to return a radius of 180/pi() so that distances are in degrees.

Functions are provided to support input in latitude and longitude (in degrees), to support output of latitude and longitude, to calculate the great circle distance between two points and to easily specify a bounding box usable for index searches.

The provided functions are shown in Table F.5.

Table F.5. Cube-Based Earthdistance Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>earth() → float8</td>
<td>Returns the assumed radius of the Earth.</td>
</tr>
<tr>
<td>sec_to_gc (float8) → float8</td>
<td>Converts the normal straight line (secant) distance between two points on the surface of the Earth to the great circle distance between them.</td>
</tr>
<tr>
<td>gc_to_sec (float8) → float8</td>
<td>Converts the great circle distance between two points on the surface of the Earth to the normal straight line (secant) distance between them.</td>
</tr>
<tr>
<td>ll_to_earth (float8, float8) → earth</td>
<td></td>
</tr>
</tbody>
</table>
### Function

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returns the location of a point on the surface of the Earth given its latitude (argument 1) and longitude (argument 2) in degrees.</td>
</tr>
</tbody>
</table>

**latitude** \(\texttt{\text{earth}}\rightarrow\texttt{float8}\)

- Returns the latitude in degrees of a point on the surface of the Earth.

**longitude** \(\texttt{\text{earth}}\rightarrow\texttt{float8}\)

- Returns the longitude in degrees of a point on the surface of the Earth.

**earth_distance** \(\texttt{\text{earth,earth}}\rightarrow\texttt{float8}\)

- Returns the great circle distance between two points on the surface of the Earth.

**earth_box** \(\texttt{\text{earth,\text{float8}}}\rightarrow\texttt{cube}\)

- Returns a box suitable for an indexed search using the **cube** \(\texttt{@>}\) operator for points within a given great circle distance of a location. Some points in this box are further than the specified great circle distance from the location, so a second check using **earth_distance** should be included in the query.

### F.14.2. Point-Based Earth Distances

The second part of the module relies on representing Earth locations as values of type **point**, in which the first component is taken to represent longitude in degrees, and the second component is taken to represent latitude in degrees. Points are taken as (longitude, latitude) and not vice versa because longitude is closer to the intuitive idea of x-axis and latitude to y-axis.

A single operator is provided, shown in Table F.6.

#### Table F.6. Point-Based Earthdistance Operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>point</strong> (\texttt{@&gt;}) <strong>point</strong> (\rightarrow\texttt{float8})</td>
<td>Computes the distance in statute miles between two points on the Earth's surface.</td>
</tr>
</tbody>
</table>

Note that unlike the **cube**-based part of the module, units are hardwired here: changing the **earth()** function will not affect the results of this operator.

One disadvantage of the longitude/latitude representation is that you need to be careful about the edge conditions near the poles and near +/- 180 degrees of longitude. The **cube**-based representation avoids these discontinuities.

### F.15. fasttrun

The **fasttrun** module provides transaction unsafe function to truncate temporary tables without growing **pg_class** size.

This module is required for 1C Enterprise support.

Fast truncate operation is not transactional, so its results cannot be rolled back and become immediately visible in all sessions regardless of isolation level.

#### F.15.1. Function

There is a function call example:

```
select fasttruncate('TABLE_NAME');
```

#### F.15.2. Test example

For tests you can use this example:
create or replace function f() returns void as $$
begin
  for i in 1..1000
    loop
      PERFORM fasttruncate('tt1');
    end loop;
  end;
$$ language plpgsql;

F.15.3. Authors

Teodor Sigaev <teodor@sigaev.ru>

F.16. file_fdw

The file_fdw module provides the foreign-data wrapper file_fdw, which can be used to access data files in the server's file system, or to execute programs on the server and read their output. The data file or program output must be in a format that can be read by `COPY FROM`; see COPY for details. Access to data files is currently read-only.

A foreign table created using this wrapper can have the following options:

filename
  Specifies the file to be read. Relative paths are relative to the data directory. Either filename or program must be specified, but not both.

program
  Specifies the command to be executed. The standard output of this command will be read as though COPY FROM PROGRAM were used. Either program or filename must be specified, but not both.

format
  Specifies the data format, the same as COPY's FORMAT option.

header
  Specifies whether the data has a header line, the same as COPY's HEADER option.

delimiter
  Specifies the data delimiter character, the same as COPY's DELIMITER option.

quote
  Specifies the data quote character, the same as COPY's QUOTE option.

escape
  Specifies the data escape character, the same as COPY's ESCAPE option.

null
  Specifies the data null string, the same as COPY's NULL option.

encoding
  Specifies the data encoding, the same as COPY's ENCODING option.

Note that while COPY allows options such as HEADER to be specified without a corresponding value, the foreign table option syntax requires a value to be present in all cases. To activate COPY options typically written without a value, you can pass the value TRUE, since all such options are Booleans.

A column of a foreign table created using this wrapper can have the following options:
Additional Supplied Modules

force_not_null

This is a Boolean option. If true, it specifies that values of the column should not be matched against the null string (that is, the table-level null option). This has the same effect as listing the column in COPY’s FORCE_NOT_NULL option.

force_null

This is a Boolean option. If true, it specifies that values of the column which match the null string are returned as NULL even if the value is quoted. Without this option, only unquoted values matching the null string are returned as NULL. This has the same effect as listing the column in COPY’s FORCE_NULL option.

COPY’s FORCE_QUOTE option is currently not supported by file_fdw.

These options can only be specified for a foreign table or its columns, not in the options of the file_fdw foreign-data wrapper, nor in the options of a server or user mapping using the wrapper.

Changing table-level options requires being a superuser or having the privileges of the role pg_read_server_files (to use a filename) or the role pg_execute_server_program (to use a program), for security reasons: only certain users should be able to control which file is read or which program is run. In principle regular users could be allowed to change the other options, but that’s not supported at present.

When specifying the program option, keep in mind that the option string is executed by the shell. If you need to pass any arguments to the command that come from an untrusted source, you must be careful to strip or escape any characters that might have special meaning to the shell. For security reasons, it is best to use a fixed command string, or at least avoid passing any user input in it.

For a foreign table using file_fdw, EXPLAIN shows the name of the file to be read or program to be run. For a file, unless COSTS OFF is specified, the file size (in bytes) is shown as well.

Example F.1. Create a Foreign Table for Postgres Pro CSV Logs

One of the obvious uses for file_fdw is to make the Postgres Pro activity log available as a table for querying. To do this, first you must be logging to a CSV file, which here we will call pglog.csv. First, install file_fdw as an extension:

```
CREATE EXTENSION file_fdw;
```

Then create a foreign server:

```
CREATE SERVER pglog FOREIGN DATA WRAPPER file_fdw;
```

Now you are ready to create the foreign data table. Using the CREATE FOREIGN TABLE command, you will need to define the columns for the table, the CSV file name, and its format:

```
CREATE FOREIGN TABLE pglog (  
  log_time timestamp(3) with time zone,  
  user_name text,  
  database_name text,  
  process_id integer,  
  connection_from text,  
  session_id text,  
  session_line_num bigint,  
  command_tag text,  
  session_start_time timestamp with time zone,  
  virtual_transaction_id text,  
  transaction_id bigint,  
  error_severity text,  
  sql_state_code text,  
  message text,  
  detail text,  
  hint text,
```

2294
Additional Supplied Modules

```
internal_query text,
internal_query_pos integer,
context text,
query text,
query_pos integer,
location text,
application_name text,
backend_type text,
leader_pid integer,
query_id bigint
) SERVER pglog
OPTIONS ( filename 'log/pglog.csv', format 'csv' );
```

That's it — now you can query your log directly. In production, of course, you would need to define some way to deal with log rotation.

**F.17. fulleq**

The `fulleq` module provides additional equivalence operator for compatibility with Microsoft SQL Server.

This module is required for 1C Enterprise support.

**F.17.1. Overview**

The Postgres Pro equivalence operator is defined to return NULL when both operands are NULLs. However, the Microsoft SQL Servers family traditionally defines other semantic for equivalence operator, where operator returns TRUE in the case of both nulled operands. This module provides such operator with MS SQL semantic.

**F.17.2. Operator fulleq**

The `==` operator is defined for the following data types:

- `bool`
- `bytea`
- `char`
- `name`
- `int2`
- `int4`
- `int8`
- `int2vector`
- `text`
- `oid`
- `xid`
- `cid`
- `oidvector`
- `float4`
- `float8`
- `abstime`
- `reltime`
- `macaddr`
- `inet`
Additional Supplied Modules

- cidr
- varchar
- date
- time
- timestamp
- timestamptz
- interval
- timetz

F.17.3. Authors

Teodor Sigaev <teodor@sigaev.ru>

F.18. fuzzystrmatch

The fuzzystrmatch module provides several functions to determine similarities and distance between strings.

Caution

At present, the soundex, metaphone, dmetaphone, and dmetaphone_alt functions do not work well with multibyte encodings (such as UTF-8).

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.18.1. Soundex

The Soundex system is a method of matching similar-sounding names by converting them to the same code. It was initially used by the United States Census in 1880, 1900, and 1910. Note that Soundex is not very useful for non-English names.

The fuzzystrmatch module provides two functions for working with Soundex codes:

soundex(text) returns text

difference(text, text) returns int

The soundex function converts a string to its Soundex code. The difference function converts two strings to their Soundex codes and then reports the number of matching code positions. Since Soundex codes have four characters, the result ranges from zero to four, with zero being no match and four being an exact match. (Thus, the function is misnamed — similarity would have been a better name.)

Here are some usage examples:

```
SELECT soundex('hello world!');

SELECT soundex('Anne'), soundex('Ann'), difference('Anne', 'Ann');
SELECT soundex('Anne'), soundex('Andrew'), difference('Anne', 'Andrew');
SELECT soundex('Anne'), soundex('Margaret'), difference('Anne', 'Margaret');

CREATE TABLE s (nm text);

INSERT INTO s VALUES ('john');
INSERT INTO s VALUES ('joan');
INSERT INTO s VALUES ('wobbly');
INSERT INTO s VALUES ('jack');
```
SELECT * FROM s WHERE soundex(nm) = soundex('john');
SELECT * FROM s WHERE difference(s.nm, 'john') > 2;

F.18.2. Levenshtein

This function calculates the Levenshtein distance between two strings:

```sql
levenshtein(text source, text target, int ins_cost, int del_cost, int sub_cost) returns int
levenshtein(text source, text target) returns int
levenshtein_less_equal(text source, text target, int ins_cost, int del_cost, int sub_cost, int max_d) returns int
levenshtein_less_equal(text source, text target, int max_d) returns int
```

Both `source` and `target` can be any non-null string, with a maximum of 255 characters. The cost parameters specify how much to charge for a character insertion, deletion, or substitution, respectively. You can omit the cost parameters, as in the second version of the function; in that case they all default to 1.

`levenshtein_less_equal` is an accelerated version of the Levenshtein function for use when only small distances are of interest. If the actual distance is less than or equal to `max_d`, then `levenshtein_less_equal` returns the correct distance; otherwise it returns some value greater than `max_d`. If `max_d` is negative then the behavior is the same as `levenshtein`.

Examples:

```sql
test=# SELECT levenshtein('GUMBO', 'GAMBOL');
levenshtein
---------
2
(1 row)
test=# SELECT levenshtein('GUMBO', 'GAMBOL', 2, 1, 1);
levenshtein
---------
3
(1 row)
test=# SELECT levenshtein_less_equal('extensive', 'exhaustive', 2);
levenshtein_less_equal
----------------------
3
(1 row)
test=# SELECT levenshtein_less_equal('extensive', 'exhaustive', 4);
levenshtein_less_equal
----------------------
4
(1 row)
```

F.18.3. Metaphone

Metaphone, like Soundex, is based on the idea of constructing a representative code for an input string. Two strings are then deemed similar if they have the same codes.

This function calculates the metaphone code of an input string:

```sql
metaphone(text source, int max_output_length) returns text
```
source has to be a non-null string with a maximum of 255 characters. max_output_length sets the maximum length of the output metaphone code; if longer, the output is truncated to this length.

Example:

test=# SELECT metaphone('GUMBO', 4);
metaphone
-------
KM
(1 row)

F.18.4. Double Metaphone

The Double Metaphone system computes two “sounds like” strings for a given input string — a “primary” and an “alternate”. In most cases they are the same, but for non-English names especially they can be a bit different, depending on pronunciation. These functions compute the primary and alternate codes:

dmetaphone(text source) returns text
dmetaphone_alt(text source) returns text

There is no length limit on the input strings.

Example:

test=# SELECT dmetaphone('gumbo');
dmetaphone
-------
KMP
(1 row)

F.19. hstore

This module implements the hstore data type for storing sets of key/value pairs within a single Postgres Pro value. This can be useful in various scenarios, such as rows with many attributes that are rarely examined, or semi-structured data. Keys and values are simply text strings.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.19.1. hstore External Representation

The text representation of an hstore, used for input and output, includes zero or more key=>value pairs separated by commas. Some examples:

k => v
foo => bar, baz => whatever
"1-a" => "anything at all"

The order of the pairs is not significant (and may not be reproduced on output). Whitespace between pairs or around the => sign is ignored. Double-quote keys and values that include whitespace, commas, =s or >s. To include a double quote or a backslash in a key or value, escape it with a backslash.

Each key in an hstore is unique. If you declare an hstore with duplicate keys, only one will be stored in the hstore and there is no guarantee as to which will be kept:

SELECT 'a=>1,a=>2':hstore;
  hstore
-------
"a"=>"1"

A value (but not a key) can be an SQL NULL. For example:

key => NULL

The NULL keyword is case-insensitive. Double-quote the NULL to treat it as the ordinary string “NULL”.

2298
Additional Supplied Modules

Note
Keep in mind that the hstore text format, when used for input, applies before any required quoting
or escaping. If you are passing an hstore literal via a parameter, then no additional processing
is needed. But if you're passing it as a quoted literal constant, then any single-quote characters
and (depending on the setting of the standard_conforming_strings conﬁguration parameter)
backslash characters need to be escaped correctly. See Section 4.1.2.1 for more on the handling
of string constants.
On output, double quotes always surround keys and values, even when it's not strictly necessary.

F.19.2. hstore Operators and Functions
The operators provided by the hstore module are shown in Table F.7, the functions in Table F.8.
Table F.7. hstore Operators

Operator
Description
Example(s)
hstore -> text → text
Returns value associated with given key, or NULL if not present.
'a=>x, b=>y'::hstore -> 'a' → x
hstore -> text[] → text[]
Returns values associated with given keys, or NULL if not present.
'a=>x, b=>y, c=>z'::hstore -> ARRAY['c','a']
→ {"z","x"}
hstore || hstore → hstore
Concatenates two hstores.
'a=>b, c=>d'::hstore || 'c=>x, d=>q'::hstore

→ "a"=>"b", "c"=>"x", "d"=>"q"

hstore ? text → boolean
Does hstore contain key?
'a=>1'::hstore ? 'a' → t
hstore ?& text[] → boolean
Does hstore contain all the speciﬁed keys?
'a=>1,b=>2'::hstore ?& ARRAY['a','b']

→t

hstore ?| text[] → boolean
Does hstore contain any of the speciﬁed keys?
'a=>1,b=>2'::hstore ?| ARRAY['b','c']
→t
hstore @> hstore → boolean
Does left operand contain right?
'a=>b, b=>1, c=>NULL'::hstore @> 'b=>1'

→t

hstore <@ hstore → boolean
Is left operand contained in right?
'a=>c'::hstore <@ 'a=>b, b=>1, c=>NULL'

→f

hstore - text → hstore
Deletes key from left operand.
'a=>1, b=>2, c=>3'::hstore - 'b'::text
hstore - text[] → hstore
Deletes keys from left operand.
2299

→ "a"=>"1", "c"=>"3"

</tr>
<tr>
<td><code>populate_record(anyelement, hstore) → anyelement</code></td>
<td>Replaces fields in the left operand (which must be a composite type) with matching values from hstore.</td>
<td><code>populate_record(ROW(1,2), 'f1=&gt;42':hstore) → (42,2)</code></td>
</tr>
</tbody>
</table>

In addition to these operators and functions, values of the hstore type can be subscripted, allowing them to act like associative arrays. Only a single subscript of type text can be specified; it is interpreted as a key and the corresponding value is fetched or stored. For example,

```sql
CREATE TABLE mytable (h hstore);
INSERT INTO mytable VALUES ('a=>b, c=>d');
SELECT h[\'a\'] FROM mytable;
  h
 b
(1 row)
UPDATE mytable SET h[\'c\'] = 'new';
SELECT h FROM mytable;
  h
  "a">="b", "c">="new"
(1 row)
```

A subscripted fetch returns NULL if the subscript is NULL or that key does not exist in the hstore. (Thus, a subscripted fetch is not greatly different from the -> operator.) A subscripted update fails if the subscript is NULL; otherwise, it replaces the value for that key, adding an entry to the hstore if the key does not already exist.

### F.19.3. Indexes

hstore has GiST and GIN index support for the @>, ?, ?& and ?| operators. For example:

```sql
CREATE INDEX hidx ON testhstore USING GIST (h);
```
CREATE INDEX hidx ON testhstore USING GIN (h);

gist_hstore_ops GiST opclass approximates a set of key/value pairs as a bitmap signature. Its optional integer parameter siglen determines the signature length in bytes. The default length is 16 bytes. Valid values of signature length are between 1 and 2048 bytes. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

Example of creating such an index with a signature length of 32 bytes:

CREATE INDEX hidx ON testhstore USING GIST (h gist_hstore_ops(siglen=32));

hstore also supports btree or hash indexes for the = operator. This allows hstore columns to be declared UNIQUE, or to be used in GROUP BY, ORDER BY or DISTINCT expressions. The sort ordering for hstore values is not particularly useful, but these indexes may be useful for equivalence lookups. Create indexes for = comparisons as follows:

CREATE INDEX hidx ON testhstore USING BTREE (h);
CREATE INDEX hidx ON testhstore USING HASH (h);

F.19.4. Examples

Add a key, or update an existing key with a new value:

UPDATE tab SET h['c'] = '3';

Another way to do the same thing is:

UPDATE tab SET h = h || hstore('c', '3');

If multiple keys are to be added or changed in one operation, the concatenation approach is more efficient than subscribing:

UPDATE tab SET h = h || hstore(array['q', 'w'], array['11', '12']);

Delete a key:

UPDATE tab SET h = delete(h, 'k1');

Convert a record to an hstore:

CREATE TABLE test (col1 integer, col2 text, col3 text);
INSERT INTO test VALUES (123, 'foo', 'bar');

SELECT hstore(t) FROM test AS t;
   hstore
---------------
  "col1"=>"123", "col2"=>"foo", "col3"=>"bar"
(1 row)

Convert an hstore to a predefined record type:

CREATE TABLE test (col1 integer, col2 text, col3 text);

SELECT * FROM populate_record(null::test, 
   "col1"=>"456", "col2"=>"zzz");
col1 | col2 | col3
-------+------+
 456   | zzz   |
(1 row)

Modify an existing record using the values from an hstore:
CREATE TABLE test (col1 integer, col2 text, col3 text);
INSERT INTO test VALUES (123, 'foo', 'bar');

SELECT (r).* FROM (SELECT t #= 'col3'="baz" AS r FROM test t) s;

<table>
<thead>
<tr>
<th>col1</th>
<th>col2</th>
<th>col3</th>
</tr>
</thead>
<tbody>
<tr>
<td>123</td>
<td>foo</td>
<td>baz</td>
</tr>
</tbody>
</table>

(1 row)

F.19.5. Statistics

The hstore type, because of its intrinsic liberality, could contain a lot of different keys. Checking for valid keys is the task of the application. The following examples demonstrate several techniques for checking keys and obtaining statistics.

Simple example:

SELECT * FROM each('aaa=>bq, b=>NULL, ""=>1');

Using a table:

CREATE TABLE stat AS SELECT (each(h)).key, (each(h)).value FROM testhstore;

Online statistics:

SELECT key, count(*) FROM (SELECT (each(h)).key FROM testhstore) AS stat GROUP BY key ORDER BY count DESC, key;

<table>
<thead>
<tr>
<th>key</th>
<th>count</th>
</tr>
</thead>
<tbody>
<tr>
<td>line</td>
<td>883</td>
</tr>
<tr>
<td>query</td>
<td>207</td>
</tr>
<tr>
<td>pos</td>
<td>203</td>
</tr>
<tr>
<td>node</td>
<td>202</td>
</tr>
<tr>
<td>space</td>
<td>197</td>
</tr>
<tr>
<td>status</td>
<td>195</td>
</tr>
<tr>
<td>public</td>
<td>194</td>
</tr>
<tr>
<td>title</td>
<td>190</td>
</tr>
<tr>
<td>org</td>
<td>189</td>
</tr>
</tbody>
</table>

F.19.6. Compatibility

As of PostgreSQL 9.0, hstore uses a different internal representation than previous versions. This presents no obstacle for dump/restore upgrades since the text representation (used in the dump) is unchanged.

In the event of a binary upgrade, upward compatibility is maintained by having the new code recognize old-format data. This will entail a slight performance penalty when processing data that has not yet been modified by the new code. It is possible to force an upgrade of all values in a table column by doing an UPDATE statement as follows:

UPDATE tablename SET hstorecol = hstorecol || '';

Another way to do it is:

ALTER TABLE tablename ALTER hstorecol TYPE hstore USING hstorecol || '';

The ALTER TABLE method requires an ACCESS EXCLUSIVE lock on the table, but does not result in bloating the table with old row versions.
F.19.7. Transforms

Additional extensions are available that implement transforms for the hstore type for the languages PL/Perl and PL/Python. The extensions for PL/Perl are called hstore_plperl and hstore_plperlu, for trusted and untrusted PL/Perl. If you install these transforms and specify them when creating a function, hstore values are mapped to Perl hashes. The extensions for PL/Python are called hstore_plpythonu, hstore_plpython2u, and hstore_plpython3u (see Section 44.1 for the PL/Python naming convention). If you use them, hstore values are mapped to Python dictionaries.

Caution

It is strongly recommended that the transform extensions be installed in the same schema as hstore. Otherwise there are installation-time security hazards if a transform extension’s schema contains objects defined by a hostile user.

F.19.8. Authors

Oleg Bartunov <oleg@sai.msu.su>, Moscow, Moscow University, Russia

Teodor Sigaev <teodor@sigaev.ru>, Moscow, Delta-Soft Ltd., Russia

Additional enhancements by Andrew Gierth <andrew@tao11.riddles.org.uk>, United Kingdom

F.20. Hunspell Dictionaries Modules

These modules provide Hunspell dictionaries for various languages. Upon installation of the module into database using CREATE EXTENSION command, text search dictionary and configuration objects in the public schema appear.

Table F.9. Modules

<table>
<thead>
<tr>
<th>Language</th>
<th>Extension name</th>
<th>Dictionary name</th>
<th>Configuration name</th>
</tr>
</thead>
<tbody>
<tr>
<td>American English</td>
<td>hunspell_en_us</td>
<td>english_hunspell</td>
<td>english_hunspell</td>
</tr>
<tr>
<td>Dutch</td>
<td>hunspell_nl_nl</td>
<td>dutch_hunspell</td>
<td>dutch_hunspell</td>
</tr>
<tr>
<td>French</td>
<td>hunspell_fr</td>
<td>french_hunspell</td>
<td>french_hunspell</td>
</tr>
<tr>
<td>Russian</td>
<td>hunspell_ru_ru</td>
<td>russian_hunspell</td>
<td>russian_hunspell</td>
</tr>
</tbody>
</table>

F.20.1. Examples

Text search objects will be created after installation of a dictionary module. We can test created configuration:

```
SELECT * FROM ts_debug('english_hunspell', 'abilities');
alias   |   description   |   token   |          dictionaries           |
dictionary    |  lexemes
-------------+-----------------+-----------+---------------------------------
+------------------+-----------
asciiword | Word, all ASCII | abilities | {english_hunspell,english_stem} |
english_hunspell | {ability}   (1 row)
```

Or you can create your own text search configuration. For example, with the created dictionaries and with the Snowball dictionary you can create mixed russian-english configuration:

```
CREATE TEXT SEARCH CONFIGURATION russian_en (}
```
COPY = simple

ALTER TEXT SEARCH CONFIGURATION russian_en
ALTER MAPPING FOR asciword, asciihword, hword_asciipart
  WITH english_hunspell, english_stem;

ALTER TEXT SEARCH CONFIGURATION russian_en
ALTER MAPPING FOR word, hword, hword_part
  WITH russian_hunspell, russian_stem;

You can create mixed dictionaries only for languages with different alphabets. If languages have similar alphabets then Postgres Pro can not decide which dictionary should be used.

A text search configuration which is created with a dictionary module is ready to use. For example, in this text you can search some words:

```
SELECT to_tsvector('english_hunspell', 'The blue whale is the largest animal');
```

```
to_tsvector
    'animal':7 'blue':2 'large':6 'whale':3
(1 row)
```

Search query might looks like this:

```
SELECT to_tsvector('english_hunspell', 'The blue whale is the largest animal')
  @@ to_tsquery('english_hunspell', 'large & whale');
?column?
----------
t
(1 row)
```

With this configurations you can search a text using GIN or GIST indexes. For example, there is a table with GIN index:

```
CREATE TABLE table1 (t varchar);
INSERT INTO table1 VALUES ('The blue whale is the largest animal');
CREATE INDEX t_idx ON table1 USING GIN (to_tsvector('english_hunspell', "t"));
```

For this table you can execute the following query:

```
SELECT * FROM table1 where to_tsvector('english_hunspell', t)
  @@ to_tsquery('english_hunspell', 'blue & animal');
```

```
t
-----------------------
The blue whale is the largest animal
(1 row)
```

F.21. intagg

The intagg module provides an integer aggregator and an enumerator. intagg is now obsolete, because there are built-in functions that provide a superset of its capabilities. However, the module is still provided as a compatibility wrapper around the built-in functions.

F.21.1. Functions

The aggregator is an aggregate function int_array_aggregate(integer) that produces an integer array containing exactly the integers it is fed. This is a wrapper around array_agg, which does the same thing for any array type.
The enumerator is a function `int_array_enum(integer[])` that returns `setof integer`. It is essentially the reverse operation of the aggregator: given an array of integers, expand it into a set of rows. This is a wrapper around `unnest`, which does the same thing for any array type.

**F.21.2. Sample Uses**

Many database systems have the notion of a one to many table. Such a table usually sits between two indexed tables, for example:

```sql
CREATE TABLE left (id INT PRIMARY KEY, ...);
CREATE TABLE right (id INT PRIMARY KEY, ...);
CREATE TABLE one_to_many(left INT REFERENCES left, right INT REFERENCES right);
```

It is typically used like this:

```sql
SELECT right.* from right JOIN one_to_many ON (right.id = one_to_many.right)
WHERE one_to_many.left = item;
```

This will return all the items in the right hand table for an entry in the left hand table. This is a very common construct in SQL.

Now, this methodology can be cumbersome with a very large number of entries in the `one_to_many` table. Often, a join like this would result in an index scan and a fetch for each right hand entry in the table for a particular left hand entry. If you have a very dynamic system, there is not much you can do. However, if you have some data which is fairly static, you can create a summary table with the aggregator:

```sql
CREATE TABLE summary AS
SELECT left, int_array_aggregate(right) AS right
FROM one_to_many
GROUP BY left;
```

This will create a table with one row per left item, and an array of right items. Now this is pretty useless without some way of using the array; that's why there is an array enumerator. You can do:

```sql
SELECT left, int_array_enum(right) FROM summary WHERE left = item;
```

The above query using `int_array_enum` produces the same results as

```sql
SELECT left, right FROM one_to_many WHERE left = item;
```

The difference is that the query against the summary table has to get only one row from the table, whereas the direct query against `one_to_many` must index scan and fetch a row for each entry.

On one system, an `EXPLAIN` showed a query with a cost of 8488 was reduced to a cost of 329. The original query was a join involving the `one_to_many` table, which was replaced by:

```sql
SELECT right, count(right) FROM
(SELECT left, int_array_enum(right) AS right
FROM summary
JOIN (SELECT left FROM left_table WHERE left = item) AS lefts
ON (summary.left = lefts.left)
) AS list
GROUP BY right
ORDER BY count DESC;
```

**F.22. intarray**

The `intarray` module provides a number of useful functions and operators for manipulating null-free arrays of integers. There is also support for indexed searches using some of the operators.

All of these operations will throw an error if a supplied array contains any NULL elements.

Many of these operations are only sensible for one-dimensional arrays. Although they will accept input arrays of more dimensions, the data is treated as though it were a linear array in storage order.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.
**F.22.1. intarray Functions and Operators**

The functions provided by the intarray module are shown in Table F.10, the operators in Table F.11.

### Table F.10. intarray Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>Example(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>icount (integer[]) → integer</td>
<td>Returns the number of elements in the array.</td>
<td>icount('1,2,3'::integer[]) → 3</td>
</tr>
<tr>
<td>sort (integer[], dir text) → integer[]</td>
<td>Sorts the array in either ascending or descending order. dir must be asc or desc.</td>
<td>sort('1,3,2'::integer[], 'desc') → {3,2,1}</td>
</tr>
<tr>
<td>sort_asc (integer[]) → integer[]</td>
<td>Sorts in ascending order.</td>
<td>sort_asc(array[11,77,44]) → {11,44,77}</td>
</tr>
<tr>
<td>sort_desc (integer[]) → integer[]</td>
<td>Sorts in descending order.</td>
<td>sort_desc(array[11,77,44]) → {77,44,11}</td>
</tr>
<tr>
<td>uniq (integer[]) → integer[]</td>
<td>Removes adjacent duplicates.</td>
<td>uniq(sort('1,2,3,2,1'::integer[])) → {1,2,3}</td>
</tr>
<tr>
<td>idx (integer[], item integer) → integer</td>
<td>Returns index of the first array element matching item, or 0 if no match.</td>
<td>idx(array[11,22,33,22,11], 22) → 2</td>
</tr>
<tr>
<td>subarray (integer[], start integer, len integer) → integer[]</td>
<td>Extracts the portion of the array starting at position start, with len elements.</td>
<td>subarray('1,2,3,2,1'::integer[], 2, 3) → {2,3,2}</td>
</tr>
<tr>
<td>subarray (integer[], start integer) → integer[]</td>
<td>Extracts the portion of the array starting at position start.</td>
<td>subarray('1,2,3,2,1'::integer[], 2) → {2,3,2,1}</td>
</tr>
<tr>
<td>intset (integer) → integer[]</td>
<td>Makes a single-element array.</td>
<td>intset(42) → {42}</td>
</tr>
</tbody>
</table>

### Table F.11. intarray Operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer[] &amp;&amp; integer[] → boolean</td>
<td>Do arrays overlap (have at least one element in common)?</td>
</tr>
<tr>
<td>integer[] @&gt; integer[] → boolean</td>
<td>Does left array contain right array?</td>
</tr>
<tr>
<td>integer[] @@ integer[] → boolean</td>
<td>Is left array contained in right array?</td>
</tr>
</tbody>
</table>
### Additional Supplied Modules

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td># integer[] → integer</td>
<td>Returns the number of elements in the array.</td>
</tr>
<tr>
<td>integer[] # integer → integer</td>
<td>Returns index of the first array element matching the right argument, or 0 if no match. (Same as <code>idx</code> function.)</td>
</tr>
<tr>
<td>integer[] + integer → integer[]</td>
<td>Adds element to end of array.</td>
</tr>
<tr>
<td>integer[] + integer[] → integer[]</td>
<td>Concatenates the arrays.</td>
</tr>
<tr>
<td>integer[] − integer → integer[]</td>
<td>Removes entries matching the right argument from the array.</td>
</tr>
<tr>
<td>integer[] − integer[] → integer[]</td>
<td>Removes elements of the right array from the left array.</td>
</tr>
<tr>
<td>integer[]</td>
<td>integer → integer[]</td>
</tr>
<tr>
<td>integer[]</td>
<td>integer[] → integer[]</td>
</tr>
<tr>
<td>integer[] &amp; integer[] → integer[]</td>
<td>Computes the intersection of the arguments.</td>
</tr>
<tr>
<td>integer[] @@ query_int → boolean</td>
<td>Does array satisfy query? (see below)</td>
</tr>
<tr>
<td>query_int ~ integer[] → boolean</td>
<td>Does array satisfy query? (commutator of @@)</td>
</tr>
</tbody>
</table>

The operators `&&`, `@>`, and `<@` are equivalent to Postgres Pro’s built-in operators of the same names, except that they work only on integer arrays that do not contain nulls, while the built-in operators work for any array type. This restriction makes them faster than the built-in operators in many cases.

The @@ and ~ operators test whether an array satisfies a query, which is expressed as a value of a specialized data type `query_int`. A query consists of integer values that are checked against the elements of the array, possibly combined using the operators `&` (AND), `|` (OR), and `!` (NOT). Parentheses can be used as needed. For example, the query `1 & (2 | 3)` matches arrays that contain 1 and also contain either 2 or 3.

#### F.22.2. Index Support

`intarray` provides index support for the `&&`, `@>`, and @@ operators, as well as regular array equality.

Two parameterized GIST index operator classes are provided: `gist__int_ops` (used by default) is suitable for small- to medium-size data sets, while `gist__intbig_ops` uses a larger signature and is more suitable for indexing large data sets (i.e., columns containing a large number of distinct array values). The implementation uses an RD-tree data structure with built-in lossy compression.

`gist__int_ops` approximates an integer set as an array of integer ranges. Its optional integer parameter `numranges` determines the maximum number of ranges in one index key. The default value of `numranges` is 100. Valid values are between 1 and 253. Using larger arrays as GIST index keys leads to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

`gist__intbig_ops` approximates an integer set as a bitmap signature. Its optional integer parameter `siglen` determines the signature length in bytes. The default signature length is 16 bytes. Valid values
of signature length are between 1 and 2024 bytes. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

There is also a non-default GIN operator class `gin__int_ops`, which supports these operators as well as `<@`.

The choice between GiST and GIN indexing depends on the relative performance characteristics of GiST and GIN, which are discussed elsewhere.

### F.22.3. Example

-- a message can be in one or more “sections”
```sql
CREATE TABLE message (mid INT PRIMARY KEY, sections INT[], ...);
```

-- create specialized index with signature length of 32 bytes
```sql
CREATE INDEX message_rdtree_idx ON message USING GIST (sections gist__intbig_ops (siglen = 32));
```

-- select messages in section 1 OR 2 - OVERLAP operator
```sql
SELECT message.mid FROM message WHERE message.sections && '{1,2}';
```

-- select messages in sections 1 AND 2 - CONTAINS operator
```sql
SELECT message.mid FROM message WHERE message.sections @> '{1,2}';
```

-- the same, using QUERY operator
```sql
SELECT message.mid FROM message WHERE message.sections @@ '1&2':query_int;
```

### F.22.4. Authors

All work was done by Teodor Sigaev (<teodor@sigaev.ru>) and Oleg Bartunov (<oleg@sai.msu.su>). See [http://www.sai.msu.su/~megera/postgres/gist/](http://www.sai.msu.su/~megera/postgres/gist/) for additional information. Andrey Oktyabrski did a great work on adding new functions and operations.

### F.23. isn

The `isn` module provides data types for the following international product numbering standards: EAN13, UPC, ISBN (books), ISMN (music), and ISSN (serials). Numbers are validated on input according to a hard-coded list of prefixes; this list of prefixes is also used to hyphenate numbers on output. Since new prefixes are assigned from time to time, the list of prefixes may be out of date. It is hoped that a future version of this module will obtain the prefix list from one or more tables that can be easily updated by users as needed; however, at present, the list can only be updated by modifying the source code and recompiling. Alternatively, prefix validation and hyphenation support may be dropped from a future version of this module.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.23.1. Data Types

Table F.12 shows the data types provided by the `isn` module.

#### Table F.12. `isn` Data Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAN13</td>
<td>European Article Numbers, always displayed in the EAN13 display format</td>
</tr>
<tr>
<td>ISBN13</td>
<td>International Standard Book Numbers to be displayed in the new EAN13 display format</td>
</tr>
</tbody>
</table>
### Additional Supplied Modules

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISMN13</td>
<td>International Standard Music Numbers to be displayed in the new EAN13 display format</td>
</tr>
<tr>
<td>ISSN13</td>
<td>International Standard Serial Numbers to be displayed in the new EAN13 display format</td>
</tr>
<tr>
<td>ISBN</td>
<td>International Standard Book Numbers to be displayed in the old short display format</td>
</tr>
<tr>
<td>ISMN</td>
<td>International Standard Music Numbers to be displayed in the old short display format</td>
</tr>
<tr>
<td>ISSN</td>
<td>International Standard Serial Numbers to be displayed in the old short display format</td>
</tr>
<tr>
<td>UPC</td>
<td>Universal Product Codes</td>
</tr>
</tbody>
</table>

Some notes:

1. ISBN13, ISMN13, ISSN13 numbers are all EAN13 numbers.
2. EAN13 numbers aren't always ISBN13, ISMN13 or ISSN13 (some are).
3. Some ISBN13 numbers can be displayed as ISBN.
4. Some ISMN13 numbers can be displayed as ISMN.
5. Some ISSN13 numbers can be displayed as ISSN.
6. UPC numbers are a subset of the EAN13 numbers (they are basically EAN13 without the first 0 digit).
7. All UPC, ISBN, ISMN and ISSN numbers can be represented as EAN13 numbers.

Internally, all these types use the same representation (a 64-bit integer), and all are interchangeable. Multiple types are provided to control display formatting and to permit tighter validity checking of input that is supposed to denote one particular type of number.

The **ISBN, ISMN, and ISSN** types will display the short version of the number (ISxN 10) whenever it’s possible, and will show ISxN 13 format for numbers that do not fit in the short version. The **EAN13, ISBN13, ISMN13 and ISSN13** types will always display the long version of the ISxN (EAN13).

### F.23.2. Casts

The **isn** module provides the following pairs of type casts:

- ISBN13 <=> EAN13
- ISMN13 <=> EAN13
- ISSN13 <=> EAN13
- ISBN <=> EAN13
- ISMN <=> EAN13
- ISSN <=> EAN13
- UPC <=> EAN13
- ISMN <=> ISMN13
- ISSN <=> ISSN13

When casting from EAN13 to another type, there is a run-time check that the value is within the domain of the other type, and an error is thrown if not. The other casts are simply relabelings that will always succeed.
F.23.3. Functions and Operators  

The isn module provides the standard comparison operators, plus B-tree and hash indexing support for all these data types. In addition there are several specialized functions; shown in Table F.13. In this table, isn means any one of the module's data types.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>isn_weak (boolean) → boolean</td>
<td>Sets the weak input mode, and returns new setting.</td>
</tr>
<tr>
<td>isn_weak () → boolean</td>
<td>Returns the current status of the weak mode.</td>
</tr>
<tr>
<td>make_valid (isn) → isn</td>
<td>Validates an invalid number (clears the invalid flag).</td>
</tr>
<tr>
<td>is_valid (isn) → boolean</td>
<td>Checks for the presence of the invalid flag.</td>
</tr>
</tbody>
</table>

Weak mode is used to be able to insert invalid data into a table. Invalid means the check digit is wrong, not that there are missing numbers.

Why would you want to use the weak mode? Well, it could be that you have a huge collection of ISBN numbers, and that there are so many of them that for weird reasons some have the wrong check digit (perhaps the numbers were scanned from a printed list and the OCR got the numbers wrong, perhaps the numbers were manually captured... who knows). Anyway, the point is you might want to clean the mess up, but you still want to be able to have all the numbers in your database and maybe use an external tool to locate the invalid numbers in the database so you can verify the information and validate it more easily; so for example you'd want to select all the invalid numbers in the table.

When you insert invalid numbers in a table using the weak mode, the number will be inserted with the corrected check digit, but it will be displayed with an exclamation mark (!) at the end, for example 0-11-000322-5!. This invalid marker can be checked with the is_valid function and cleared with the make_valid function.

You can also force the insertion of invalid numbers even when not in the weak mode, by appending the ! character at the end of the number.

Another special feature is that during input, you can write ? in place of the check digit, and the correct check digit will be inserted automatically.

F.23.4. Examples

-- Using the types directly:
SELECT isbn('978-0-393-04002-9');
SELECT isbn13('0901690546');
SELECT issn('1436-4522');

-- Casting types:
-- note that you can only cast from ean13 to another type when the
-- number would be valid in the realm of the target type;
-- thus, the following will NOT work: select isbn(ean13('0220356483481'));
-- but these will:
SELECT upc(ean13('0220356483481'));
SELECT ean13(upc('220356483481'));

-- Create a table with a single column to hold ISBN numbers:
CREATE TABLE test (id isbn);
INSERT INTO test VALUES('9780393040029');

--Automatically calculate check digits (observe the '?'):
INSERT INTO test VALUES('220500896?');
INSERT INTO test VALUES('978055215372?');
SELECT issn('3251231?');
SELECT ismn('979047213542?');

--Using the weak mode:
SELECT isn_weak(true);
INSERT INTO test VALUES('978-0-11-000533-4');
INSERT INTO test VALUES('9780141219307');
INSERT INTO test VALUES('2-205-00876-X');
SELECT isn_weak(false);

SELECT id FROM test WHERE NOT is_valid(id);
UPDATE test SET id = make_valid(id) WHERE id = '2-205-00876-X!';
SELECT * FROM test;
SELECT isbn13(id) FROM test;

F.23.5. Bibliography

The information to implement this module was collected from several sites, including:
- https://www.isbn-international.org/
- https://www.issn.org/
- https://www.ismn-international.org/
- https://www.wikipedia.org/

The prefixes used for hyphenation were also compiled from:
- https://www.gs1.org/standards/id-keys
- https://www.isbn-international.org/content/isbn-users-manual
- https://www.ismn-international.org/ranges.html

Care was taken during the creation of the algorithms and they were meticulously verified against the suggested algorithms in the official ISBN, ISMN, ISSN User Manuals.

F.23.6. Author

Germán Méndez Bravo (Kronuz), 2004–2006

This module was inspired by Garrett A. Wollman's isbn_issn code.

F.24. jsquery

JsQuery is a language to query jsonb data type. Its primary goal is to provide an additional functionality for jsonb, such as a simple and effective way for search in nested objects and arrays, as well as additional comparison operators with index support.

JsQuery is implemented by means of a jsquery data type (similar to tsquery) and the @@ match operator for jsonb.
F.24.1. Installation
Postgres Pro distribution includes jsquery as a contrib module. Once you complete Postgres Pro Standard installation, create the jsquery extension, as follows:

```
CREATE EXTENSION jsquery;
```

F.24.2. JSON query language
JsQuery extension contains jsquery datatype which represents whole JSON query as a single value (like tsquery does for fulltext search). The query is an expression on JSON-document values.

Simple expression is specified as path binary_operator value or path unary_operator. See the following examples.

- `x = "abc"` - value of key "x" is equal to "abc";
- `@> [4, 5, "zzz"]` - the JSON document is an array containing values 4, 5 and "zzz";
- `"abc xyz" >= 10` - value of key "abc xyz" is greater than or equal to 10;
- `volume IS NUMERIC` - type of key "volume" is numeric.
- `$ = true` - the whole JSON document is just a true.
- `similar_ids.# > 5` - `similar_ids` is an array or object of length greater than 5;
- `similar_product_ids.# = "0684824396"` - array `similar_product_ids` contains string "0684824396".
- `*.color = "red"` - there is object somewhere which key "color" has value "red".
- `foo = *` - key "foo" exists in object.

Path selects set of JSON values to be checked using given operators. In the simplest case, path is just a key name. In general, path is key names and placeholders combined by dot signs. Path can use the following placeholders:

- `#` - any index of array;
- `#N` - Nth index of array;
- `%` - any key of object;
- `*` - any sequence of array indexes and object keys;
- `@#` - length of array or object, could be only used as last component of path;
- `$` - the whole JSON document as single value, could be only the whole path.

Expression is true when operator is true against at least one value selected by path.

Key names could be given either with or without double quotes. Key names without double quotes shouldn't contain spaces, start with number, or concur with jsquery keyword.

The supported binary operators are:

- Equality operator: `=`;
- Numeric comparison operators: `>`, `>=`, `<`, `<=`;
- Search in the list of scalar values using `IN` operator;
- Array comparison operators: `&&` (overlap), `@>` (contains), `<@` (contained in).
- Filtering operator: `~~`. Taking `jsonb` data as the left operand and a `jsquery` expression as the right operand, this operator checks that `jsonb` data contains any entries that satisfy the condition provided in a `jsquery` expression and returns an array of such entries, if any.

The supported unary operators are:

- Check for existence operator: `=`;
- Check for type operators: `IS ARRAY`, `IS NUMERIC`, `IS OBJECT`, `IS STRING` and `IS BOOLEAN`.

Expressions could be complex. Complex expression is a set of expressions combined by logical operators (AND, OR, NOT) and grouped using parentheses.

Examples of complex expressions are given below.
Prefix expressions are expressions given in the form path (subexpression). In this case path selects JSON values to be checked using given subexpression. Check results are aggregated in the same way as in simple expressions.

• #(a = 1 AND b = 2)  - an array contains an element where the a key is 2 and the b key is 2
• %(x >= 10 AND x <= 20)  - an object contains a key with a value between 10 and 20

Path also could contain the following special placeholders with "every" semantics:

• #: - every index of array;
• %: - every key of object;
• *: - every sequence of array indexes and object keys.

Consider the following example.

%(#:($ >= 0 AND $ <= 1))
This example could be read as follows: there is at least one key for which the value is an array of numerics between 0 and 1.

We can rewrite this example in the following form with extra parentheses.

%(#:($ >= 0 AND $ <= 1))
The first placeholder % checks that expression in parentheses is true for at least one value in object. The second placeholder #: checks that the value is an array and all its elements satisfy expressions in parentheses.

We can rewrite this example without #: placeholder as follows.

%(NOT #(NOT ($ >= 0 AND $ <= 1)) AND $ IS ARRAY)
In this example we transform assertion that every element of array satisfies some condition to assertion that there is no one element which doesn't satisfy the same condition.

Some examples of using paths are given below.

• numbers.#: IS NUMERIC - every element of "numbers" array is numeric.
• *:($ IS OBJECT OR $ IS BOOLEAN) - JSON is a structure of nested objects with booleans as leaf values.
• #:.(%:($ >= 0 AND $ <= 1)) - each element of array is object containing only numeric values between 0 and 1.
• documents.#:.%: = *: "documents" is an array of objects containing at least one key.
• %:.#:($ IS STRING) - JSON object contains at least one array of strings.
• #.% = true - at least one array element is an object that contains at least one "true" value.

Usage of path operators and parentheses needs some explanation. When same path operators are used multiple times they may refer to different values while you can refer to the same value multiple times by using parentheses and $ operator. See the following examples.

• # < 10 AND # > 20 - there is an element less than 10 and another element greater than 20.
• #($ < 10 AND $ > 20) - there is an element that is both less than 10 and greater than 20 (impossible).
• #($ >= 10 AND $ <= 20) - there is an element between 10 and 20.
• # >= 10 AND # <= 20 - there is an element greater than or equal to 10 and another element less than or equal to 20. The query can be satisfied by an array with no elements between 10 and 20, for instance [0,30].

Same rules apply when you search inside objects and branchy structures.

Type checking operators and "every" placeholders are useful for document schema validation. JsQuery matching operator @@ is immutable and can be used in CHECK constraint. See the following example.
CREATE TABLE js (  id serial,  data jsonb,  CHECK (data @@  
   name IS STRING AND  
similar_ids.#: IS NUMERIC AND  
points.#:(x IS NUMERIC AND y IS NUMERIC)::jsquery));

In this example check constraint validates that in "data" jsonb column: value of "name" key is string, value of "similar_ids" key is array of numerics, value of "points" key is array of objects which contain numeric values in "x" and "y" keys.

See our pgconf.eu presentation for more examples.

F.24.3. GIN indexes

JsQuery extension contains two operator classes (opclasses) for GIN which provide different kinds of query optimization.

• jsonb_path_value_ops  
• jsonb_value_path_ops

In each of two GIN opclasses jsonb documents are decomposed into entries. Each entry is associated with a particular value and its path. Difference between opclasses is in the entry representation, comparison, and usage for search optimization.

For example, jsonb document {"a": [{"b": "xyz", "c": true}, 10], "d": {"e": [7, false]}} would be decomposed into the following entries:

• "a".#.b."xyz"  
• "a".#.c.true  
• "a".#.10  
• "d".e.#.7  
• "d"."e".#.false

Since JsQuery doesn’t support search in a particular array index, we consider all array elements to be equivalent. Thus, each array element is marked with the same # sign in the path.

Major problem in the entries representation is its size. In the given example key "a" is presented three times. In the large branchy documents with long keys size of naive entries representation becomes unreasonable. Both opclasses address this issue but in a slightly different way.

F.24.3.1. jsonb_path_value_ops

jsonb_path_value_ops represents entry as pair of path hash and value. The following pseudocode illustrates it.

(hash(path_item_1.path_item_2. ... .path_item_n); value)

In comparison of entries path hash is the higher part of entry and value is its lower part. This determines the features of this opclass. Since path is hashed and it is higher part of entry we need to know the full path to the value in order to use it for search. However, once path is specified we can use both exact and range searches very efficiently.

F.24.3.2. jsonb_value_path_ops

jsonb_value_path_ops represents entry as pair of value and bloom filter of path.

(value; bloom(path_item_1) | bloom(path_item_2) | ... | bloom(path_item_n))

In comparison of entries value is the higher part of entry and bloom filter of path is its lower part. This determines the features of this opclass. Since value is the higher part of entry we can perform only exact value search efficiently. Range value search is possible as well but we would have to filter all
the different paths where matching values occur. Bloom filter over path items allows index usage for conditions containing % and * in their paths.

F.24.3.3. Query optimization

JsQuery opclasses perform complex query optimization. Thus it's valuable for developer or administrator to see the result of such optimization. Unfortunately, opclasses aren't allowed to do any custom output to the EXPLAIN. That's why JsQuery provides the following functions which allows to see how particular opclass optimizes given query.

- gin_debug_query_path_value(jsquery) - for jsonb_path_value_ops
- gin_debug_query_value_path(jsquery) - for jsonb_value_path_ops

Result of these functions is a textual representation of query tree which leaves are GIN search entries. The following examples show different results of query optimization by different opclasses.

```sql
# SELECT gin_debug_query_path_value('x = 1 AND (*.y = 1 OR y = 2)');
gin_debug_query_path_value
----------------------------
x = 1 , entry 0           +

# SELECT gin_debug_query_value_path('x = 1 AND (*.y = 1 OR y = 2)');
gin_debug_query_value_path
----------------------------
AND                       +
x = 1 , entry 0         +
OR                      +
  *.y = 1 , entry 1     +
y = 2 , entry 2       +
```

Unfortunately, jsonb has no statistics yet. That's why JsQuery optimizer has to do imperative decision while selecting conditions to be evaluated using index. This decision is made by assumption that some condition types are less selective than others. Optimizer divides conditions into the following selectivity class (listed by descending of selectivity).

1. Equality (x = c)
2. Range (c1 < x < c2)
3. Inequality (x > c)
4. Is (x is type)
5. Any (x = *)

Optimizer evades index evaluation of less selective conditions when possible. For example, in the x = 1 AND y > 0 query x = 1 is assumed to be more selective than y > 0. That's why index isn't used for evaluation of y > 0.

```sql
# SELECT gin_debug_query_path_value('x = 1 AND y > 0');
gin_debug_query_path_value
----------------------------
x = 1 , entry 0           +

With lack of statistics decisions made by optimizer can be inaccurate. That's why JsQuery supports hints.

Comments /*-- index */ and /*-- noindex */ placed in the conditions force optimizer to use and not to use index correspondingly.

```sql
SELECT gin_debug_query_path_value('x = 1 AND y /*-- index */ > 0');
gin_debug_query_path_value
----------------------------
AND                       +
x = 1 , entry 0         +
y > 0 , entry 1        +

SELECT gin_debug_query_path_value('x /*-- noindex */ = 1 AND y > 0');
```
F.25. lo

The lo module provides support for managing Large Objects (also called LOs or BLOBs). This includes a data type lo and a trigger lo_manage.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.25.1. Rationale

One of the problems with the JDBC driver (and this affects the ODBC driver also), is that the specification assumes that references to BLOBs (Binary Large OBjects) are stored within a table, and if that entry is changed, the associated BLOB is deleted from the database.

As Postgres Pro stands, this doesn't occur. Large objects are treated as objects in their own right; a table entry can reference a large object by OID, but there can be multiple table entries referencing the same large object OID, so the system doesn't delete the large object just because you change or remove one such entry.

Now this is fine for Postgres Pro-specific applications, but standard code using JDBC or ODBC won't delete the objects, resulting in orphan objects — objects that are not referenced by anything, and simply occupy disk space.

The lo module allows fixing this by attaching a trigger to tables that contain LO reference columns. The trigger essentially just does a lo_unlink whenever you delete or modify a value referencing a large object. When you use this trigger, you are assuming that there is only one database reference to any large object that is referenced in a trigger-controlled column!

The module also provides a data type lo, which is really just a domain of the oid type. This is useful for differentiating database columns that hold large object references from those that are OIDs of other things. You don’t have to use the lo type to use the trigger, but it may be convenient to use it to keep track of which columns in your database represent large objects that you are managing with the trigger. It is also rumored that the ODBC driver gets confused if you don't use lo for BLOB columns.

F.25.2. How to Use It

Here's a simple example of usage:

```sql
CREATE TABLE image (title text, raster lo);

CREATE TRIGGER t_raster BEFORE UPDATE OR DELETE ON image
  FOR EACH ROW EXECUTE FUNCTION lo_manage(raster);
```

For each column that will contain unique references to large objects, create a BEFORE UPDATE OR DELETE trigger, and give the column name as the sole trigger argument. You can also restrict the trigger to only execute on updates to the column by using BEFORE UPDATE OF column_name. If you need multiple lo columns in the same table, create a separate trigger for each one, remembering to give a different name to each trigger on the same table.
**F.25.3. Limitations**

- Dropping a table will still orphan any objects it contains, as the trigger is not executed. You can avoid this by preceding the `DROP TABLE` with `DELETE FROM table`.

  `TRUNCATE` has the same hazard.

  If you already have, or suspect you have, orphaned large objects, see the `vacuumlo` module to help you clean them up. It's a good idea to run `vacuumlo` occasionally as a back-stop to the `lo_manage` trigger.

- Some frontends may create their own tables, and will not create the associated trigger(s). Also, users may not remember (or know) to create the triggers.

**F.25.4. Author**

Peter Mount <peter@retep.org.uk>

**F.26. ltree**

This module implements a data type `ltree` for representing labels of data stored in a hierarchical tree-like structure. Extensive facilities for searching through label trees are provided.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

**F.26.1. Definitions**

A `label` is a sequence of alphanumeric characters and underscores (for example, in C locale the characters A-Za-z0-9_ are allowed). Labels must be less than 256 characters long.

**Examples:** 42, `Personal_Services`

A `label path` is a sequence of zero or more labels separated by dots, for example `L1.L2.L3`, representing a path from the root of a hierarchical tree to a particular node. The length of a label path cannot exceed 65535 labels.

**Example:** `Top.Countries.Europe.Russia`

The `ltree` module provides several data types:

- `ltree` stores a label path.
- `lquery` represents a regular-expression-like pattern for matching `ltree` values. A simple word matches that label within a path. A star symbol (`*`) matches zero or more labels. These can be joined with dots to form a pattern that must match the whole label path. For example:

  ```
  foo       Match the exact label path foo
  *.foo.*   Match any label path containing the label foo
  *.foo     Match any label path whose last label is foo
  ```

  Both star symbols and simple words can be quantified to restrict how many labels they can match:

  ```
  *{n}       Match exactly n labels
  *{n,}      Match at least n labels
  *{n,m}     Match at least n but not more than m labels
  *{,m}      Match at most m labels — same as *{0,m}
  foo{n,m}   Match at least n but not more than m occurrences of foo
  foo{,}     Match any number of occurrences of foo, including zero
  ```

  In the absence of any explicit quantifier, the default for a star symbol is to match any number of labels (that is, `{,}`) while the default for a non-star item is to match exactly once (that is, `{1}`).
There are several modifiers that can be put at the end of a non-star \texttt{lquery} item to make it match more than just the exact match:

\begin{itemize}
  \item @ \hspace{1cm} Match case-insensitively, for example \texttt{a@} matches \texttt{A}
  \item * \hspace{1cm} Match any label with this prefix, for example \texttt{foo*} matches \texttt{foobar}
  \item % \hspace{1cm} Match initial underscore-separated words
\end{itemize}

The behavior of \% is a bit complicated. It tries to match words rather than the entire label. For example \texttt{foo_bar\%} matches \texttt{foo_bar_baz} but not \texttt{foo_barbaz}. If combined with *, prefix matching applies to each word separately, for example \texttt{foo_bar\%*} matches \texttt{foo1_bar2_baz} but not \texttt{foo1_br2_baz}.

Also, you can write several possibly-modified non-star items separated with \texttt{|} (OR) to match any of those items, and you can put \texttt{!} (NOT) at the start of a non-star group to match any label that doesn’t match any of the alternatives. A quantifier, if any, goes at the end of the group; it means some number of matches for the group as a whole (that is, some number of labels matching or not matching any of the alternatives).

Here’s an annotated example of \texttt{lquery}:

\texttt{Top.*\{0,2\}.sport@*.football|tennis\{1,\}.Russ*|Spain}

\begin{itemize}
  \item a. \hspace{1cm} begins with the label \texttt{Top}
  \item b. \hspace{1cm} and next has zero to two labels before
  \item c. \hspace{1cm} a label beginning with the case-insensitive prefix \texttt{sport}
  \item d. \hspace{1cm} then has one or more labels, none of which match \texttt{football} nor \texttt{tennis}
  \item e. \hspace{1cm} and then ends with a label beginning with \texttt{Russ} or exactly matching \texttt{Spain}.
\end{itemize}

\texttt{ltxtquery} represents a full-text-search-like pattern for matching \texttt{ltree} values. An \texttt{ltxtquery} value contains words, possibly with the modifiers @, *, % at the end; the modifiers have the same meanings as in \texttt{lquery}. Words can be combined with \& (AND), | (OR), ! (NOT), and parentheses. The key difference from \texttt{lquery} is that \texttt{ltxtquery} matches words without regard to their position in the label path.

Here’s an example \texttt{ltxtquery}:

\texttt{Europe \& Russia@\& !Transportation}

This will match paths that contain the label \texttt{Europe} and any label beginning with \texttt{Russia} (case-insensitive), but not paths containing the label \texttt{Transportation}. The location of these words within the path is not important. Also, when \% is used, the word can be matched to any underscore-separated word within a label, regardless of position.

\textbf{Note:} \texttt{ltxtquery} allows whitespace between symbols, but \texttt{ltree} and \texttt{lquery} do not.

\section*{F.26.2. Operators and Functions}

Type \texttt{ltree} has the usual comparison operators =, =, <, >, <=, >=. Comparison sorts in the order of a tree traversal, with the children of a node sorted by label text. In addition, the specialized operators shown in Table \ref{table-f.14} are available.

\begin{table}[h]

<tr>
<td>Does array contain any path matching ltxtquery?</td>
</tr>
<tr>
<td>ltree[] ?@&gt; ltree (\rightarrow) ltree</td>
</tr>
<tr>
<td>Returns first array entry that is an ancestor of ltree, or NULL if none.</td>
</tr>
<tr>
<td>ltree[] ?&lt;@ ltree (\rightarrow) ltree</td>
</tr>
<tr>
<td>Returns first array entry that is a descendant of ltree, or NULL if none.</td>
</tr>
<tr>
<td>ltree[] ?~ lquery (\rightarrow) ltree</td>
</tr>
<tr>
<td>Returns first array entry that matches lquery, or NULL if none.</td>
</tr>
<tr>
<td>ltree[] ?@ ltxtquery (\rightarrow) ltree</td>
</tr>
<tr>
<td>Returns first array entry that matches ltxtquery, or NULL if none.</td>
</tr>
</tbody>
</table>

The operators `<@, @>, @` and `~` have analogues `^<@, ^@>, ^@, ^~`, which are the same except they do not use indexes. These are useful only for testing purposes.
The available functions are shown in Table F.15.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>Example(s)</th>

<td>Casts text to ltree.</td>
<td>ttree2text</td>
</tr>
<tr>
<td>lca</td>
<td>Computes longest common ancestor of paths (up to 8 arguments are supported).</td>
<td>lca('1.2.3', '1.2.3.4.5.6') → 1.2</td>
</tr>
</tbody>
</table>

F.26.3. Indexes

ltree supports several types of indexes that can speed up the indicated operators:

- B-tree index over ltree: <, <=, =, >, >=
- GiST index over ltree (gist_ltree_ops opclass): <, <=, =, >, @>, <@, @, ~, ?

gist_ltree_ops GiST opclass approximates a set of path labels as a bitmap signature. Its optional integer parameter siglen determines the signature length in bytes. The default signature length is 8 bytes. Valid values of signature length are between 1 and 2024 bytes. Longer signatures lead to a
more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

Example of creating such an index with the default signature length of 8 bytes:

```
CREATE INDEX path_gist_idx ON test USING GIST (path);
```

Example of creating such an index with a signature length of 100 bytes:

```
CREATE INDEX path_gist_idx ON test USING GIST (path gist_ltree_ops(siglen=100));
```

- GiST index over \[\text{ltree[]} (\text{gist__ltree_ops\_opclass})\]: \text{ltree[]} <@ ltree, ltree @> ltree[], @, ~, ?

\text{gist__ltree_ops\_opclass} GiST opclass works similarly to \text{gist_ltree_ops} and also takes signature length as a parameter. The default value of \text{siglen in gist__ltree_ops is 28 bytes.}

Example of creating such an index with the default signature length of 28 bytes:

```
CREATE INDEX path_gist_idx ON test USING GIST (array_path);
```

Example of creating such an index with a signature length of 100 bytes:

```
CREATE INDEX path_gist_idx ON test USING GIST (array_path gist__ltree_ops(siglen=100));
```

Note: This index type is lossy.

### F.26.4. Example

This example uses the following data (also available in file \text{contrib/ltree/ltreetest.sql} in the source distribution):

```
CREATE TABLE test (path ltree);
INSERT INTO test VALUES ('Top');
INSERT INTO test VALUES ('Top.Science');
INSERT INTO test VALUES ('Top.Science.Astronomy');
INSERT INTO test VALUES ('Top.Science.Astronomy.Astrophysics');
INSERT INTO test VALUES ('Top.Science.Astronomy.Cosmology');
INSERT INTO test VALUES ('Top.Hobbies');
INSERT INTO test VALUES ('Top.Hobbies.Amateurs_Astronomy');
INSERT INTO test VALUES ('Top.Collections');
INSERT INTO test VALUES ('Top.Collections.Pictures');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy.Astronauts');
CREATE index path_gist_idx ON test USING GIST (path);
CREATE index path_idx ON test USING BTREE (path);
```

Now, we have a table \text{test} populated with data describing the hierarchy shown below:

```
Top
 /   |   \
Science Hobbies Collections
 /    |   \
Astronomy Amateurs_Astronomy Pictures
 / |   \
Astrophysics Cosmology Astronomy
 / |   \
Galaxies Stars Astronauts
```

We can do inheritance:
Here are some examples of path matching:

Here are some examples of full text search:

Path construction using functions:
We could simplify this by creating an SQL function that inserts a label at a specified position in a path:

```sql
CREATE FUNCTION ins_label(ltree, int, text) RETURNS ltree
AS 'select subpath($1,0,$2) || $3 || subpath($1,$2);'
LANGUAGE SQL IMMUTABLE;
```

```
ltree
test=> SELECT ins_label(path,2,'Space') FROM test WHERE path <@
'Top.Science.Astronomy';
            ins_label
--------------------------
Top.Science.Space.Astronomy
(3 rows)
```

**F.26.5. Transforms**

Additional extensions are available that implement transforms for the `ltree` type for PL/Python. The extensions are called `ltree_plpythonu`, `ltree_plpython2u`, and `ltree_plpython3u` (see Section 44.1 for the PL/Python naming convention). If you install these transforms and specify them when creating a function, `ltree` values are mapped to Python lists. (The reverse is currently not supported, however.)

**Caution**

It is strongly recommended that the transform extensions be installed in the same schema as `ltree`. Otherwise there are installation-time security hazards if a transform extension's schema contains objects defined by a hostile user.

**F.26.6. Authors**

All work was done by Teodor Sigaev (<teodor@stack.net>) and Oleg Bartunov (<oleg@sai.msu.su>). See [http://www.sai.msu.su/~megera/postgres/gist/](http://www.sai.msu.su/~megera/postgres/gist/) for additional information. Authors would like to thank Eugeny Rodichev for helpful discussions. Comments and bug reports are welcome.

**F.27. mchar**

The `mchar` module provides additional data types for compatibility with Microsoft SQL Server (MS SQL).

**F.27.1. Overview**

This module has been designed to improve 1C Enterprise support, most popular Russian CRM and ERP system.

It implements types MCHAR and MVARCHAR, which are bug-to-bug compatible with MS SQL CHAR and VARCHAR respectively. Additionally, these types use libicu for comparison and case conversion, so their behavior is identical across different operating systems.

Postgres Pro also includes `citext` extension which provides types similar to MCHAR. But this extension doesn't emulate MS-SQL behavior concerning end-of-value whitespace.

Differences from Postgres Pro standard CHAR and VARCHAR are:

- Case insensitive comparison
- Handling of the whitespace at the end of string
- These types are always stored as two-byte unicode value regardless of database encoding.

**F.27.2. Additional types**

- `mchar` — analog of the MS SQL char type
Additional Supplied Modules

- mvarchar — analog of the MS SQL varchar type

**F.27.3. MCHAR and MVARCHAR features**

- Defines length(str) function
- Defines substr(str, pos[, length]) function
- Defines || operator, which would be applied to concatenate any (mchar and mvarchar) arguments
- Defines set of operators: <, <=, =, >=, > for case-insensitive comparison (LibICU)
- Defines set of operators: &&, &&<, &&<=, &&=, &&>=, &&> to case-sensitive comparison (LibICU)
- Implicit cast between mchar and mvarchar types
- B-tree and Hash-index support
- The LIKE [ESCAPE] operator support
- The SIMILAR TO [ESCAPE] operator support
- The ~ operator (POSIX regexp) support
- Index support for the LIKE operator

**F.27.4. Authors**

Oleg Bartunov <oleg@sai.msu.ru>
Teodor Sigaev <teodor@sigaev.ru>

**F.28. online_analyze**

The online_analyze module provides a set of features that immediately update statistics after INSERT, UPDATE, DELETE, or SELECT INTO operations for the affected tables.

**F.28.1. Module Loading**

To use online_analyze module, load the shared library:

```
LOAD 'online_analyze';
```

**F.28.2. Module Configuration**

You can configure online_analyze using the following custom variables (default values are shown):

- online_analyze.enable = on
  Enables online_analyze.
- online_analyze.verbose = on
  Executes ANALYZE VERBOSE.

**Note**

Since verbose is a reserved SQL key word, this parameter has to be double-quoted when used in SQL queries. For example:

```
ALTER SYSTEM SET "online_analyze.verbose" = 'off';
```

- online_analyze.scale_factor = 0.1
  Fraction of table size to start online analysis (similar to autovacuum_analyze_scale_factor).
Additional Supplied Modules

- online_analyze.threshold = 50

  Minimum number of row updates before starting online analysis (similar to `autovacuum_analyze_threshold`).

- online_analyze.min_interval = 10000

  Minimum time interval between `ANALYZE` calls per table, in milliseconds.

- online_analyze.table_type = "all"

  Type(s) of tables for online analysis. Possible values are: all, persistent, temporary, none.

- online_analyze.exclude_tables = ""

  List of tables to exclude from online analysis.

- online_analyze.include_tables = ""

  List of tables to include in online analysis (online_analyze.include_tables overrides online_analyze.exclude_tables).

- online_analyze.local_tracking = off

  Enables per-backend tracking for temporary tables by online_analyze. When this variable is set to off, online_analyze uses the default system statistics for temporary tables.

- online_analyze.lower_limit = 0

  Minimum number of rows in a table required to trigger online_analyze.

- online_analyze.capacity_threshold = 100000

  Maximum number of temporary tables to store in local cache.

F.28.3. Authors

Teodor Sigaev <teodor@sigaev.ru>

F.29. old_snapshot

The `old_snapshot` module allows inspection of the server state that is used to implement `old_snapshot_threshold`.

F.29.1. Functions

`pg_old_snapshot_time_mapping(array_offset OUT int4, end_timestamp OUT timestamptz, newest_xmin OUT xid) returns setof record`

Returns all of the entries in the server's timestamp to XID mapping. Each entry represents the newest xmin of any snapshot taken in the corresponding minute.

F.30. pageinspect

The `pageinspect` module provides functions that allow you to inspect the contents of database pages at a low level, which is useful for debugging purposes. All of these functions may be used only by superusers.

F.30.1. General Functions

`get_raw_page(relname text, fork text, blkno bigint) returns bytea`

`get_raw_page` reads the specified block of the named relation and returns a copy as a `bytea` value. This allows a single time-consistent copy of the block to be obtained. `fork` should be 'main' for
the main data fork, 'fsm' for the free space map, 'vm' for the visibility map, or 'init' for the initiali
zation fork.

get_raw_page(relname text, blkno bigint) returns bytea

A shorthand version of get_raw_page, for reading from the main fork. Equivalent to
get_raw_page(relname, 'main', blkno)

page_header(page bytea) returns record

page_header shows fields that are common to all Postgres Pro heap and index pages.

A page image obtained with get_raw_page should be passed as argument. For example:

test=# SELECT * FROM page_header(get_raw_page('pg_class', 0));

lsn | checksum | flags | lower | upper | special | pagesize | version | prune_xid
-------+----------+--------+-------+-------+---------+----------+---------+---------
0/24A1B50 | 0 | 1 | 232 | 368 | 8192 | 8192 | 4 | 0

The returned columns correspond to the fields in the PageHeaderData struct.

The checksum field is the checksum stored in the page, which might be incorrect if the page is
somehow corrupted. If data checksums are not enabled for this instance, then the value stored is
meaningless.

page_checksum(page bytea, blkno bigint) returns smallint

page_checksum computes the checksum for the page, as if it was located at the given block.

A page image obtained with get_raw_page should be passed as argument. For example:

test=# SELECT page_checksum(get_raw_page('pg_class', 0), 0);

page_checksum
---------------
13443

Note that the checksum depends on the block number, so matching block numbers should be passed
(except when doing esoteric debugging).

The checksum computed with this function can be compared with the checksum result field of the
function page_header. If data checksums are enabled for this instance, then the two values should
be equal.

fsm_page_contents(page bytea) returns text

fsm_page_contents shows the internal node structure of an FSM page. For example:

test=# SELECT fsm_page_contents(get_raw_page('pg_class', 'fsm', 0));

The output is a multiline string, with one line per node in the binary tree within the page. Only those
nodes that are not zero are printed. The so-called "next" pointer, which points to the next slot to be
returned from the page, is also printed.

F.30.2. Heap Functions

heap_page_items(page bytea) returns setof record

heap_page_items shows all line pointers on a heap page. For those line pointers that are in use, tuple
headers as well as tuple raw data are also shown. All tuples are shown, whether or not the tuples
were visible to an MVCC snapshot at the time the raw page was copied.
A heap page image obtained with `get_raw_page` should be passed as argument. For example:

test=# SELECT * FROM heap_page_items(get_raw_page('pg_class', 0));

The `heap_tuple_infomask_flags` function can be used to unpack the flag bits of `t_infomask` and `t_infomask2` for heap tuples.

tuple_data_split(rel_oid oid, t_data bytea, t_infomask integer, t_infomask2 integer, t_bits text [, do_detoast bool]) returns bytea[]

tuple_data_split splits tuple data into attributes in the same way as backend internals.

test=# SELECT tuple_data_split('pg_class'::regclass, t_data, t_infomask, t_infomask2, t_bits) FROM heap_page_items(get_raw_page('pg_class', 0));

This function should be called with the same arguments as the return attributes of `heap_page_items`.

If `do_detoast` is true, attributes will be detoasted as needed. Default value is false.

heap_page_item_attrs(page bytea, rel_oid regclass [, do_detoast bool]) returns setof record

heap_page_item_attrs is equivalent to `heap_page_items` except that it returns tuple raw data as an array of attributes that can optionally be detoasted by `do_detoast` which is false by default.

A heap page image obtained with `get_raw_page` should be passed as argument. For example:

test=# SELECT * FROM heap_page_item_attrs(get_raw_page('pg_class', 0), 'pg_class'::regclass);

heap_tuple_infomask_flags(t_infomask integer, t_infomask2 integer) returns record

heap_tuple_infomask_flags decodes the `t_infomask` and `t_infomask2` returned by `heap_page_items` into a human-readable set of arrays made of flag names, with one column for all the flags and one column for combined flags. For example:

test=# SELECT t_ctid, raw_flags, combined_flags FROM heap_page_items(get_raw_page('pg_class', 0)),
   LATERAL heap_tuple_infomask_flags(t_infomask, t_infomask2) WHERE t_infomask IS NOT NULL OR t_infomask2 IS NOT NULL;

This function should be called with the same arguments as the return attributes of `heap_page_items`.

Combined flags are displayed for source-level macros that take into account the value of more than one raw bit, such as `HEAP_XMIN_FROZEN`.

F.30.3. B-Tree Functions

bt_metap(relname text) returns record

bt_metap returns information about a B-tree index's metapage. For example:

test=# SELECT * FROM bt_metap('pg_cast_oid_index');

- [ RECORD 1 ]-------------------
  magic | 340322
  version | 4
  root | 1
  level | 0
  fastroot | 1
  fastlevel | 0
  last_cleanup_num_delpages | 0
  last_cleanup_num_tuples | 230
  allequalimage | f
Additional Supplied Modules

`bt_page_stats`(relname text, blkno bigint) returns record

`bt_page_stats` returns summary information about single pages of B-tree indexes. For example:

```
test=# SELECT * FROM bt_page_stats('pg_cast_oid_index', 1);
- [ RECORD 1 ]--
| blkno | 1   |
| type  | l   |
| live_items | 224 |
| dead_items | 0   |
| avg_item_size | 16  |
| page_size | 8192 |
| free_size | 3668 |
| btpo_prev | 0   |
| btpo_next | 0   |
| btpo_level | 0  |
| btpo_flags | 3  |
```

`bt_page_items`(relname text, blkno bigint) returns setof record

`bt_page_items` returns detailed information about all of the items on a B-tree index page. For example:

```
test=# SELECT itemoffset, ctid, itemlen, nulls, vars, data, dead, htid, tids[0:2] AS some_tids
FROM bt_page_items('tenk2_hundred', 5);

<table>
<thead>
<tr>
<th>itemoffset</th>
<th>ctid</th>
<th>itemlen</th>
<th>nulls</th>
<th>vars</th>
<th>data</th>
<th>dead</th>
<th>htid</th>
<th>some_tids</th>
</tr>

</tr>
</tbody>
</table>
(13 rows)
```

This is a B-tree leaf page. All tuples that point to the table happen to be posting list tuples (all of which store a total of 100 6 byte TIDs). There is also a “high key” tuple at `itemoffset number 1. ctid`
is used to store encoded information about each tuple in this example, though leaf page tuples often store a heap TID directly in the \textit{ctid} field instead. \textit{tids} is the list of TIDs stored as a posting list.

In an internal page (not shown), the block number part of \textit{ctid} is a “downlink”, which is a block number of another page in the index itself. The offset part (the second number) of \textit{ctid} stores encoded information about the tuple, such as the number of columns present (suffix truncation may have removed unneeded suffix columns). Truncated columns are treated as having the value “minus infinity”.

\textit{htid} shows a heap TID for the tuple, regardless of the underlying tuple representation. This value may match \textit{ctid}, or may be decoded from the alternative representations used by posting list tuples and tuples from internal pages. Tuples in internal pages usually have the implementation level heap TID column truncated away, which is represented as a NULL \textit{htid} value.

Note that the first item on any non-rightmost page (any page with a non-zero value in the \textit{btpo\_next} field) is the page’s “high key”, meaning its data serves as an upper bound on all items appearing on the page, while its \textit{ctid} field does not point to another block. Also, on internal pages, the first real data item (the first item that is not a high key) reliably has every column truncated away, leaving no actual value in its data field. Such an item does have a valid downlink in its \textit{ctid} field, however.

For more details about the structure of B-tree indexes, see Section 60.4.1. For more details about deduplication and posting lists, see Section 60.4.3.

\texttt{bt\_page\_items(page bytea) returns setof record}

It is also possible to pass a page to \texttt{bt\_page\_items} as a \texttt{bytea} value. A page image obtained with \texttt{get\_raw\_page} should be passed as argument. So the last example could also be rewritten like this:

\begin{verbatim}
 test=# SELECT itemoffset, ctid, itemlen, nulls, vars, data, dead, htid, tids[0:2] AS some_tids
      FROM bt_page_items(get_raw_page('tenk2\_hundred', 5));

 itemoffset |   ctid    | itemlen | nulls | vars |          data           | dead |
-------------+-----------+---------+-------+------+-------------------------+------
 1           | (16,1)    |      16 | f     | f    | 30 00 00 00 00 00 00 00 00 |      |
 2           | (16,8292) | 616    | f     | f    | 24 00 00 00 00 00 00 00 00 00 00 | f   |
 (1,6)       |{"(1,6)","(10,22)"} | | |
 3           | (16,8292) | 616    | f     | f    | 25 00 00 00 00 00 00 00 00 00 00 00 | f   |
 (1,18)      |{"(1,18)","(4,22)"} | | |
 4           | (16,8292) | 616    | f     | f    | 26 00 00 00 00 00 00 00 00 00 00 00 | f   |
 (4,18)      |{"(4,18)","(6,17)"} | | |
 5           | (16,8292) | 616    | f     | f    | 27 00 00 00 00 00 00 00 00 00 00 00 | f   |
 (1,2)       |{"(1,2)","(1,19)"} | | |
 6           | (16,8292) | 616    | f     | f    | 28 00 00 00 00 00 00 00 00 00 00 00 | f   |

 (0,10)      |{"(0,10)","(0,14)"} | | |
 10          | (16,8292) | 616    | f     | f    | 2c 00 00 00 00 00 00 00 00 00 00 00 | f   |
 (1,3)       |{"(1,3)","(3,9)"} | | |
 11          | (16,8292) | 616    | f     | f    | 2d 00 00 00 00 00 00 00 00 00 00 00 | f   |
 (6,28)      |{"(6,28)","(11,1)"} | | |
 12          | (16,8292) | 616    | f     | f    | 2e 00 00 00 00 00 00 00 00 00 00 00 | f   |
 (0,27)      |{"(0,27)","(1,13)"} | | |

2331
Additional Supplied Modules

All the other details are the same as explained in the previous item.

F.30.4. BRIN Functions

\texttt{brin\_page\_type(page \text{ bytea }) \text{ returns text}}

\texttt{brin\_page\_type} returns the page type of the given BRIN index page, or throws an error if the page is not a valid BRIN page. For example:

\begin{verbatim}
  test=# SELECT brin_page_type(get_raw_page('brinidx', 0));
  brin_page_type
  ----------------
  meta
\end{verbatim}

\texttt{brin\_metapage\_info(page \text{ bytea }) \text{ returns record}}

\texttt{brin\_metapage\_info} returns assorted information about a BRIN index metapage. For example:

\begin{verbatim}
  test=# SELECT * FROM brin_metapage_info(get_raw_page('brinidx', 0));
    magic    | version | pagesperrange | lastrevmappage
  -----------------------------------------------
       0xA8109CFA |       1 |             4 |              2
\end{verbatim}

\texttt{brin\_revmap\_data(page \text{ bytea }) \text{ returns setof tid}}

\texttt{brin\_revmap\_data} returns the list of tuple identifiers in a BRIN index range map page. For example:

\begin{verbatim}
  test=# SELECT * FROM brin_revmap_data(get_raw_page('brinidx', 2)) LIMIT 5;
    pages
  ---------
    (6,137)
    (6,138)
    (6,139)
    (6,140)
    (6,141)
\end{verbatim}

\texttt{brin\_page\_items(page \text{ bytea }, index \text{ oid }) \text{ returns setof record}}

\texttt{brin\_page\_items} returns the data stored in the BRIN data page. For example:

\begin{verbatim}
  test=# SELECT * FROM brin_page_items(get_raw_page('brinidx', 5),
    'brinidx')
    ORDER BY blknum, attnum LIMIT 6;
  itemoffset | blknum | attnum | allnulls | hasnulls | placeholder |    value
  -----------------------------------------------
        137 |      0 |      1 | t        | f        | f           | {1 .. 88}
        137 |      0 |      2 | f        | f        | f           | {89 .. 176}
        138 |      4 |      1 | t        | f        | f           | {177 .. 264}
        138 |      4 |      2 | f        | f        | f           | {177 .. 264}
        139 |      8 |      1 | t        | f        | f           | {177 .. 264}
        139 |      8 |      2 | f        | f        | f           | {177 .. 264}
\end{verbatim}

The returned columns correspond to the fields in the \texttt{BrinMemTuple} and \texttt{BrinValues} structs.

F.30.5. GIN Functions

\texttt{gin\_metapage\_info(page \text{ bytea }) \text{ returns record}}

\texttt{gin\_metapage\_info} returns information about a GIN index metapage. For example:
test=# SELECT * FROM gin_metapage_info(get_raw_page('gin_index', 0));

- [ RECORD 1 ]-=-=-=-=-=-=-=-
  pending_head | 4294967295
  pending_tail | 4294967295
  tail_free_size | 0
  n_pending_pages | 0
  n_pending_tuples | 0
  n_total_pages | 7
  n_entry_pages | 6
  n_data_pages | 0
  n_entries | 693
  version | 2

gin_page_opaque_info(page bytea) returns record

gin_page_opaque_info returns information about a GIN index opaque area, like the page type. For example:

test=# SELECT * FROM gin_page_opaque_info(get_raw_page('gin_index', 2));

  rightlink | maxoff | flags
  ----------+--------+------------------------
   5 | 0 | {data,leaf,compressed}

(1 row)

gin_leafpage_items(page bytea) returns setof record

gin_leafpage_items returns information about the data stored in a GIN leaf page. For example:

test=# SELECT first_tid, nbytes, tids[0:5] AS some_tids
  FROM gin_leafpage_items(get_raw_page('gin_test_idx', 2));

  first_tid | nbytes | some_tids
  ------------+--------+----------------------------------------
   (8,41)    | 244    | {"(8,41)","(8,43)","(8,44)","(8,45)","(8,46)"} 
   (10,45)   | 248    | {"(10,45)","(10,46)","(10,47)","(10,48)","(10,49)"} 
   (12,52)   | 248    | {"(12,52)","(12,53)","(12,54)","(12,55)","(12,56)"} 
   (14,59)   | 320    | {"(14,59)","(14,60)","(14,61)","(14,62)","(14,63)"} 
   (167,16)  | 376    | {"(167,16)","(167,17)","(167,18)","(167,19)","(167,20)"} 
   (170,30)  | 376    | {"(170,30)","(170,31)","(170,32)","(170,33)","(170,34)"} 
   (173,44)  | 197    | {"(173,44)","(173,45)","(173,46)","(173,47)","(173,48)"} 

(7 rows)

F.30.6. GiST Functions

gist_page_opaque_info(page bytea) returns record

gist_page_opaque_info returns information from a GiST index page's opaque area, such as the NSN, rightlink and page type. For example:

test=# SELECT * FROM gist_page_opaque_info(get_raw_page('test_gist_idx', 2));

  lsn | nsn | rightlink | flags
  -----+-----+-----------+--------
   0/1 | 0/0 |         1 | {leaf}

(1 row)

gist_page_items(page bytea, index_oid regclass) returns setof record

gist_page_items returns information about the data stored in a page of a GiST index. For example:

test=# SELECT * FROM gist_page_items(get_raw_page('test_gist_idx', 0),
  'test_gist_idx');

  itemoffset | ctid | itemlen | dead | keys
  ---------------+-------+---------+-------+-------------------
F.30.7. Hash Functions

hash_page_type(page bytea) returns text

hash_page_type returns page type of the given HASH index page. For example:

test=# SELECT hash_page_type(get_raw_page('con_hash_index', 0));

---

hash_page_stats(page bytea) returns setof record

hash_page_stats returns information about a bucket or overflow page of a HASH index. For example:

test=# SELECT * FROM hash_page_stats(get_raw_page('con_hash_index', 1));

---

```sql
1 | (1,65535) | 40 | f |
2 | (2,65535) | 40 | f |
3 | (3,65535) | 40 | f |
4 | (4,65535) | 40 | f |
5 | (5,65535) | 40 | f |
6 | (6,65535) | 40 | f |
7 | (7,65535) | 40 | f |
```

(7 rows)
hash_page_items(page bytea) returns setof record

hash_page_items returns information about the data stored in a bucket or overflow page of a HASH index page. For example:

test=# SELECT * FROM hash_page_items(get_raw_page('con_hash_index', 1)) LIMIT 5;

<table>
<thead>
<tr>
<th>itemoffset</th>
<th>ctid</th>
<th>data</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>(899,77)</td>
<td>1053474816</td>
</tr>
<tr>
<td>2</td>
<td>(897,29)</td>
<td>1053474816</td>
</tr>
<tr>
<td>3</td>
<td>(894,207)</td>
<td>1053474816</td>
</tr>
<tr>
<td>4</td>
<td>(892,159)</td>
<td>1053474816</td>
</tr>
<tr>
<td>5</td>
<td>(890,111)</td>
<td>1053474816</td>
</tr>
</tbody>
</table>

hash_bitmap_info(index oid, blkno bigint) returns record

hash_bitmap_info shows the status of a bit in the bitmap page for a particular overflow page of HASH index. For example:

test=# SELECT * FROM hash_bitmap_info('con_hash_index', 2052);

<table>
<thead>
<tr>
<th>bitmapblkno</th>
<th>bitmapbit</th>
<th>bitstatus</th>
</tr>
</thead>
<tbody>
<tr>
<td>65</td>
<td>3</td>
<td>t</td>
</tr>
</tbody>
</table>

hash_metapage_info(page bytea) returns record

hash_metapage_info returns information stored in the meta page of a HASH index. For example:

test=# SELECT magic, version, ntuples, ffactor, bsize, bmsize, bmshift,
| test-# maxbucket, highmask, lowmask, ovflpoint, firstfree, nmaps, procid,
| test-# regexp_replace(spares::text, '(,0)*', ',') as spares,
| test-# regexp_replace(mapp::text, '(,0)*', ',') as mapp
| test-# FROM hash_metapage_info(get_raw_page('con_hash_index', 0));

- [ RECORD 1 ]---------------------------------------------

| magic     | 105121344 |
| version   | 4         |
| ntuples   | 500500    |
| ffactor   | 40        |
| bsize     | 8152      |
| bmsize    | 4096      |
| bmshift   | 15        |
| maxbucket | 12512     |
| highmask  | 16383     |
| lowmask   | 8191      |
| ovflpoint | 28        |
| firstfree | 1204      |
| nmaps     | 1         |
| procid    | 450       |
| spares    | {0,0,0,0,0,0,1,1,1,1,1,1,1,1,3,4,4,4,45,55,58,59,508,567,628,704,1193,1202,1204} |
| mapp      | {65}      |

F.31. passwordcheck

The passwordcheck module checks users' passwords whenever they are set with CREATE ROLE or ALTER ROLE (it doesn't work, if a non-default profile is assigned to the user). If a password is considered too weak, it will be rejected and the command will terminate with an error.

To enable this module, add '$libdir/passwordcheck' to shared_preload_libraries in postgresql.conf, then restart the server.
Caution

To prevent unencrypted passwords from being sent across the network, written to the server log or otherwise stolen by a database administrator, Postgres Pro allows the user to supply pre-encrypted passwords. Many client programs make use of this functionality and encrypt the password before sending it to the server.

This limits the usefulness of the `passwordcheck` module, because in that case it can only try to guess the password. For this reason, `passwordcheck` is not recommended if your security requirements are high. It is more secure to use an external authentication method such as GSSAPI (see Chapter 19) than to rely on passwords within the database.

F.32. pg_buffercache

The `pg_buffercache` module provides a means for examining what’s happening in the shared buffer cache in real time.

The module provides a C function `pg_buffercache_pages` that returns a set of records, plus a view `pg_buffercache` that wraps the function for convenient use.

By default, use is restricted to superusers and members of the `pg_monitor` role. Access may be granted to others using `GRANT`.

F.32.1. The pg_buffercache View

The definitions of the columns exposed by the view are shown in Table F.16.

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bufferid integer</td>
<td>ID, in the range 1..shared_buffers</td>
</tr>
<tr>
<td>relfilenode oid (references pg_class .relfilenode)</td>
<td>Filenode number of the relation</td>
</tr>
<tr>
<td>reltablespace oid (references pg_tablespace .oid)</td>
<td>Tablespace OID of the relation</td>
</tr>
<tr>
<td>reldatabase oid (references pg_database .oid)</td>
<td>Database OID of the relation</td>
</tr>
<tr>
<td>relforknumber smallint</td>
<td>Fork number within the relation</td>
</tr>
<tr>
<td>relblocknumber bigint</td>
<td>Page number within the relation</td>
</tr>
<tr>
<td>isdirty boolean</td>
<td>Is the page dirty?</td>
</tr>
<tr>
<td>usagecount smallint</td>
<td>Clock-sweep access count</td>
</tr>
<tr>
<td>pinning_backends integer</td>
<td>Number of backends pinning this buffer</td>
</tr>
</tbody>
</table>

There is one row for each buffer in the shared cache. Unused buffers are shown with all fields null except `bufferid`. Shared system catalogs are shown as belonging to database zero.
Because the cache is shared by all the databases, there will normally be pages from relations not belonging to the current database. This means that there may not be matching join rows in \texttt{pg\_class} for some rows, or that there could even be incorrect joins. If you are trying to join against \texttt{pg\_class}, it's a good idea to restrict the join to rows having \texttt{reldatabase} equal to the current database's OID or zero.

Since buffer manager locks are not taken to copy the buffer state data that the view will display, accessing \texttt{pg\_buffercache} view has less impact on normal buffer activity but it doesn't provide a consistent set of results across all buffers. However, we ensure that the information of each buffer is self-consistent.

\textbf{F.32.2. Sample Output}

```
regression=# SELECT n.nspname, c.relname, count(*) AS buffers
    FROM pg_buffercache b JOIN pg_class c
    ON b.relfilenode = pg_relation_filenode(c.oid) AND
       b.reldatabase IN (0, (SELECT oid FROM pg_database
                         WHERE datname = current_database()))
    JOIN pg_namespace n ON n.oid = c.relnamespace
    GROUP BY n.nspname, c.relname
    ORDER BY 3 DESC
    LIMIT 10;
```

| nspname   |        relname         | buffers |
|-----------+------------------------+---------|
| public    | delete_test_table      |     593 |
| public    | delete_test_table_pkey |     494 |
| pg_catalog| pg_attribute           |     472 |
| public    | quad_poly_tbl          |     353 |
| public    | tenk2                  |     349 |

Design suggestions: Neil Conway \texttt{<neilc@samurai.com>}

Debugging advice: Tom Lane \texttt{<tgl@sss.pgh.pa.us>}

\textbf{F.33. \texttt{pgcrypto}}

The \texttt{pgcrypto} module provides cryptographic functions for Postgres Pro.

This module is considered “trusted”, that is, it can be installed by non-superusers who have \texttt{CREATE} privilege on the current database.

\textbf{F.33.1. General Hashing Functions}

\textbf{F.33.1.1. \texttt{digest()}}

\begin{verbatim}
digest(data text, type text) returns bytea

digest(data bytea, type text) returns bytea
```

Computes a binary hash of the given \texttt{data}. \texttt{type} is the algorithm to use. Standard algorithms are \texttt{md5}, \texttt{sha1}, \texttt{sha224}, \texttt{sha256}, \texttt{sha384} and \texttt{sha512}. If \texttt{pgcrypto} was built with OpenSSL, more algorithms are available, as detailed in Table F.20.
If you want the digest as a hexadecimal string, use `encode()` on the result. For example:

```sql
CREATE OR REPLACE FUNCTION sha1(bytea) returns text AS $$
    SELECT encode(digest($1, 'sha1'), 'hex')
$$ LANGUAGE SQL STRICT IMMUTABLE;
```

F.33.1.2. `hmac()`

`hmac(data text, key text, type text) returns bytea`
`hmac(data bytea, key bytea, type text) returns bytea`

Calculates hashed MAC for `data` with `key`. `type` is the same as in `digest()`.

This is similar to `digest()` but the hash can only be recalculated knowing the key. This prevents the scenario of someone altering data and also changing the hash to match.

If the key is larger than the hash block size it will first be hashed and the result will be used as key.

F.33.2. Password Hashing Functions

The functions `crypt()` and `gen_salt()` are specifically designed for hashing passwords. `crypt()` does the hashing and `gen_salt()` prepares algorithm parameters for it.

The algorithms in `crypt()` differ from the usual MD5 or SHA1 hashing algorithms in the following respects:

1. They are slow. As the amount of data is so small, this is the only way to make brute-forcing passwords hard.
2. They use a random value, called the `salt`, so that users having the same password will have different encrypted passwords. This is also an additional defense against reversing the algorithm.
3. They include the algorithm type in the result, so passwords hashed with different algorithms can co-exist.
4. Some of them are adaptive — that means when computers get faster, you can tune the algorithm to be slower, without introducing incompatibility with existing passwords.

Table F.17 lists the algorithms supported by the `crypt()` function.

<table>
<thead>
<tr>
<th>Algorithm</th>
<th>Max Password Length</th>
<th>Adaptive?</th>
<th>Salt Bits</th>
<th>Output Length</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bf</td>
<td>72</td>
<td>yes</td>
<td>128</td>
<td>60</td>
<td>Blowfish-based, variant 2a</td>
</tr>
<tr>
<td>md5</td>
<td>unlimited</td>
<td>no</td>
<td>48</td>
<td>34</td>
<td>MD5-based crypt</td>
</tr>
<tr>
<td>xdes</td>
<td>8</td>
<td>yes</td>
<td>24</td>
<td>20</td>
<td>Extended DES</td>
</tr>
<tr>
<td>des</td>
<td>8</td>
<td>no</td>
<td>12</td>
<td>13</td>
<td>Original UNIX crypt</td>
</tr>
</tbody>
</table>

F.33.2.1. `crypt()`

`crypt(password text, salt text) returns text`

Calculates a crypt(3)-style hash of `password`. When storing a new password, you need to use `gen_salt()` to generate a new `salt` value. To check a password, pass the stored hash value as `salt`, and test whether the result matches the stored value.

Example of setting a new password:
UPDATE ... SET pshash = crypt('new password', gen_salt('md5'));

Example of authentication:

SELECT (pshash = crypt('entered password', pshash)) AS psismatch FROM ... ;

This returns true if the entered password is correct.

F.33.2.2. gen_salt()

gensalt(type text [, iter_count integer ]) returns text

Generates a new random salt string for use in crypt(). The salt string also tells crypt() which algorithm to use.

The type parameter specifies the hashing algorithm. The accepted types are: des, xdes, md5 and bf.

The iter_count parameter lets the user specify the iteration count, for algorithms that have one. The higher the count, the more time it takes to hash the password and therefore the more time to break it. Although with too high a count the time to calculate a hash may be several years — which is somewhat impractical. If the iter_count parameter is omitted, the default iteration count is used. Allowed values for iter_count depend on the algorithm and are shown in Table F.18.

Table F.18. Iteration Counts for crypt()

<table>
<thead>
<tr>
<th>Algorithm</th>
<th>Default</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>xdes</td>
<td>725</td>
<td>1</td>
<td>16777215</td>
</tr>
<tr>
<td>bf</td>
<td>6</td>
<td>4</td>
<td>31</td>
</tr>
</tbody>
</table>

For xdes there is an additional limitation that the iteration count must be an odd number.

To pick an appropriate iteration count, consider that the original DES crypt was designed to have the speed of 4 hashes per second on the hardware of that time. Slower than 4 hashes per second would probably dampen usability. Faster than 100 hashes per second is probably too fast.

Table F.19 gives an overview of the relative slowness of different hashing algorithms. The table shows how much time it would take to try all combinations of characters in an 8-character password, assuming that the password contains either only lower case letters, or upper- and lower-case letters and numbers. In the crypt-bf entries, the number after a slash is the iter_count parameter of gen_salt.

Table F.19. Hash Algorithm Speeds

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Notes:

• The machine used is an Intel Mobile Core i3.
**Additional Supplied Modules**

- crypt-des and crypt-md5 algorithm numbers are taken from John the Ripper v1.6.38 -test output.
- md5 hash numbers are from mdcrack 1.2.
- sha1 numbers are from lcrack-20031130-beta.
- crypt-bf numbers are taken using a simple program that loops over 1000 8-character passwords. That way I can show the speed with different numbers of iterations. For reference: john -test shows 13506 loops/sec for crypt-bf/5. (The very small difference in results is in accordance with the fact that the crypt-bf implementation in pgcrypto is the same one used in John the Ripper.)

Note that “try all combinations” is not a realistic exercise. Usually password cracking is done with the help of dictionaries, which contain both regular words and various mutations of them. So, even somewhat word-like passwords could be cracked much faster than the above numbers suggest, while a 6-character non-word-like password may escape cracking. Or not.

**F.33.3. PGP Encryption Functions**

The functions here implement the encryption part of the OpenPGP ([RFC 4880](https://tools.ietf.org/html/rfc4880)) standard. Supported are both symmetric-key and public-key encryption.

An encrypted PGP message consists of 2 parts, or *packets*:

- Packet containing a session key — either symmetric-key or public-key encrypted.
- Packet containing data encrypted with the session key.

When encrypting with a symmetric key (i.e., a password):

1. The given password is hashed using a String2Key (S2K) algorithm. This is rather similar to crypt() algorithms — purposefully slow and with random salt — but it produces a full-length binary key.
2. If a separate session key is requested, a new random key will be generated. Otherwise the S2K key will be used directly as the session key.
3. If the S2K key is to be used directly, then only S2K settings will be put into the session key packet. Otherwise the session key will be encrypted with the S2K key and put into the session key packet.

When encrypting with a public key:

1. A new random session key is generated.
2. It is encrypted using the public key and put into the session key packet.

In either case the data to be encrypted is processed as follows:

1. Optional data-manipulation: compression, conversion to UTF-8, and/or conversion of line-endings.
2. The data is prefixed with a block of random bytes. This is equivalent to using a random IV.
3. A SHA1 hash of the random prefix and data is appended.
4. All this is encrypted with the session key and placed in the data packet.

**F.33.3.1. pgp_sym_encrypt ()**

```sql
pgp_sym_encrypt(data text, psw text [, options text ]) returns bytea
pgp_sym_encrypt_bytea(data bytea, psw text [, options text ]) returns bytea
```

Encrypt *data* with a symmetric PGP key *psw*. The *options* parameter can contain option settings, as described below.

**F.33.3.2. pgp_sym_decrypt ()**

```sql
pgp_sym_decrypt(msg bytea, psw text [, options text ]) returns text
pgp_sym_decrypt_bytea(msg bytea, psw text [, options text ]) returns bytea
```
Decrypt a symmetric-key-encrypted PGP message.

Decrypting bytea data with pgp_sym_decrypt is disallowed. This is to avoid outputting invalid character data. Decrypting originally textual data with pgp_sym_decrypt_bytea is fine.

The options parameter can contain option settings, as described below.

F.33.3.3. pgp_pub_encrypt()

pgp_pub_encrypt(data text, key bytea [, options text ]) returns bytea
pgp_pub_encrypt_bytea(data bytea, key bytea [, options text ]) returns bytea

Encrypt data with a public PGP key key. Giving this function a secret key will produce an error.

The options parameter can contain option settings, as described below.

F.33.3.4. pgp_pub_decrypt()

pgp_pub_decrypt(msg bytea, key bytea [, psw text [, options text ]]) returns text
pgp_pub_decrypt_bytea(msg bytea, key bytea [, psw text [, options text ]]) returns bytea

Decrypt a public-key-encrypted message. key must be the secret key corresponding to the public key that was used to encrypt. If the secret key is password-protected, you must give the password in psw. If there is no password, but you want to specify options, you need to give an empty password.

Decrypting bytea data with pgp_pub_decrypt is disallowed. This is to avoid outputting invalid character data. Decrypting originally textual data with pgp_pub_decrypt_bytea is fine.

The options parameter can contain option settings, as described below.

F.33.3.5. pgp_key_id()

pgp_key_id(bytea) returns text

pgp_key_id extracts the key ID of a PGP public or secret key. Or it gives the key ID that was used for encrypting the data, if given an encrypted message.

It can return 2 special key IDs:

- **SYMKEY**
  
  The message is encrypted with a symmetric key.

- **ANYKEY**
  
  The message is public-key encrypted, but the key ID has been removed. That means you will need to try all your secret keys on it to see which one decrypts it. pgcrypto itself does not produce such messages.

Note that different keys may have the same ID. This is rare but a normal event. The client application should then try to decrypt with each one, to see which fits — like handling ANYKEY.

F.33.3.6. armor(), dearmor()

armor(data bytea [ , keys text[], values text[] ]) returns text
dearmor(data text) returns bytea

These functions wrap/unwrap binary data into PGP ASCII-armor format, which is basically Base64 with CRC and additional formatting.

If the keys and values arrays are specified, an armor header is added to the armored format for each key/value pair. Both arrays must be single-dimensional, and they must be of the same length. The keys and values cannot contain any non-ASCII characters.
F.33.3.7. `pgp_armor_headers`

`pgp_armor_headers(data text, key out text, value out text) returns setof record`

`pgp_armor_headers()` extracts the armor headers from `data`. The return value is a set of rows with two columns, key and value. If the keys or values contain any non-ASCII characters, they are treated as UTF-8.

F.33.3.8. Options for PGP Functions

Options are named to be similar to GnuPG. An option’s value should be given after an equal sign; separate options from each other with commas. For example:

`pgp_sym_encrypt(data, psw, 'compress-algo=1, cipher-algo=aes256')`

All of the options except `convert-crlf` apply only to encrypt functions. Decrypt functions get the parameters from the PGP data.

The most interesting options are probably `compress-algo` and `unicode-mode`. The rest should have reasonable defaults.

F.33.3.8.1. `cipher-algo`

Which cipher algorithm to use.

Values: `bf`, `aes128`, `aes192`, `aes256` (OpenSSL-only: `3des`, `cast5`)
Default: `aes128`
Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`

F.33.3.8.2. `compress-algo`

Which compression algorithm to use. Only available if Postgres Pro was built with `zlib`.

Values:
- 0 - no compression
- 1 - ZIP compression
- 2 - ZLIB compression (= ZIP plus meta-data and block CRCs)
Default: 0
Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`

F.33.3.8.3. `compress-level`

How much to compress. Higher levels compress smaller but are slower. 0 disables compression.

Values: 0, 1-9
Default: 6
Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`

F.33.3.8.4. `convert-crlf`

Whether to convert \n into \r\n when encrypting and \r\n to \n when decrypting. RFC 4880 specifies that text data should be stored using \r\n line-feeds. Use this to get fully RFC-compliant behavior.

Values: 0, 1
Default: 0
Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`, `pgp_sym_decrypt`, `pgp_pub_decrypt`

F.33.3.8.5. `disable-mdc`

Do not protect data with SHA-1. The only good reason to use this option is to achieve compatibility with ancient PGP products, predating the addition of SHA-1 protected packets to RFC 4880. Recent gnupg.org and pgp.com software supports it fine.

Values: 0, 1
Additional Supplied Modules

Default: 0
Applies to: pgp_sym_encrypt, pgp_pub_encrypt

F.33.3.8.6. **sess-key**
Use separate session key. Public-key encryption always uses a separate session key; this option is for symmetric-key encryption, which by default uses the S2K key directly.

Values: 0, 1
Default: 0
Applies to: pgp_sym_encrypt

F.33.3.8.7. **s2k-mode**
Which S2K algorithm to use.

Values:
- 0 - Without salt. Dangerous!
- 1 - With salt but with fixed iteration count.
- 3 - Variable iteration count.
Default: 3
Applies to: pgp_sym_encrypt

F.33.3.8.8. **s2k-count**
The number of iterations of the S2K algorithm to use. It must be a value between 1024 and 65011712, inclusive.

Default: A random value between 65536 and 253952
Applies to: pgp_sym_encrypt, only with s2k-mode=3

F.33.3.8.9. **s2k-digest-algo**
Which digest algorithm to use in S2K calculation.

Values: md5, sha1
Default: sha1
Applies to: pgp_sym_encrypt

F.33.3.8.10. **s2k-cipher-algo**
Which cipher to use for encrypting separate session key.

Values: bf, aes, aes128, aes192, aes256
Default: use cipher-algo
Applies to: pgp_sym_encrypt

F.33.3.8.11. **unicode-mode**
Whether to convert textual data from database internal encoding to UTF-8 and back. If your database already is UTF-8, no conversion will be done, but the message will be tagged as UTF-8. Without this option it will not be.

Values: 0, 1
Default: 0
Applies to: pgp_sym_encrypt, pgp_pub_encrypt

F.33.3.9. Generating PGP Keys with GnuPG
To generate a new key:

```
gpg --gen-key
```

The preferred key type is “DSA and Elgamal”.
For RSA encryption you must create either DSA or RSA sign-only key as master and then add an RSA encryption subkey with `gpg --edit-key`.

To list keys:
`gpg --list-secret-keys`

To export a public key in ASCII-armor format:
`gpg -a --export KEYID > public.key`

To export a secret key in ASCII-armor format:
`gpg -a --export-secret-keys KEYID > secret.key`

You need to use `dearmor()` on these keys before giving them to the PGP functions. Or if you can handle binary data, you can drop `-a` from the command.

For more details see `man gpg`, *The GNU Privacy Handbook* and other documentation on https://www.gnupg.org/.

**F.33.3.10. Limitations of PGP Code**

- No support for signing. That also means that it is not checked whether the encryption subkey belongs to the master key.
- No support for encryption key as master key. As such practice is generally discouraged, this should not be a problem.
- No support for several subkeys. This may seem like a problem, as this is common practice. On the other hand, you should not use your regular GPG/PGP keys with *pgcrypto*, but create new ones, as the usage scenario is rather different.

**F.33.4. Raw Encryption Functions**

These functions only run a cipher over data; they don't have any advanced features of PGP encryption. Therefore they have some major problems:

1. They use user key directly as cipher key.
2. They don't provide any integrity checking, to see if the encrypted data was modified.
3. They expect that users manage all encryption parameters themselves, even IV.
4. They don't handle text.

So, with the introduction of PGP encryption, usage of raw encryption functions is discouraged.

```
encrypt(data bytea, key bytea, type text) returns bytea
decrypt(data bytea, key bytea, type text) returns bytea
encrypt_iv(data bytea, key bytea, iv bytea, type text) returns bytea
decrypt_iv(data bytea, key bytea, iv bytea, type text) returns bytea
```

Encrypt/decrypt data using the cipher method specified by `type`. The syntax of the `type` string is:

```
algorithm [ - mode ] [ /pad: padding ]
```

where `algorithm` is one of:

- `bf` — Blowfish
- `aes` — AES (Rijndael-128, -192 or -256)

and `mode` is one of:
• cbc — next block depends on previous (default)
• ecb — each block is encrypted separately (for testing only)

and padding is one of:
• pkcs — data may be any length (default)
• none — data must be multiple of cipher block size

So, for example, these are equivalent:

```plaintext
eencrypt(data, 'fooz', 'bf')
encrypt(data, 'fooz', 'bf-cbc/pad:pkcs')
```

In encrypt_iv and decrypt_iv, the iv parameter is the initial value for the CBC mode; it is ignored for ECB. It is clipped or padded with zeroes if not exactly block size. It defaults to all zeroes in the functions without this parameter.

**F.33.5. Random-Data Functions**

```plaintext
gen_random_bytes(count integer) returns bytea
```

Returns count cryptographically strong random bytes. At most 1024 bytes can be extracted at a time. This is to avoid draining the randomness generator pool.

```plaintext
gen_random_uuid() returns uuid
```

Returns a version 4 (random) UUID. (Obsolete, this function is now also included in core PostgreSQL.)

**F.33.6. Notes**

**F.33.6.1. Configuration**

pgcrypto configures itself according to the findings of the main Postgres Pro configure script. The options that affect it are --with-zlib and --with-ssl=openssl.

When compiled with zlib, PGP encryption functions are able to compress data before encrypting.

When compiled with OpenSSL, there will be more algorithms available. Also public-key encryption functions will be faster as OpenSSL has more optimized BIGNUM functions.

When compiled against OpenSSL 3.0.0 and later versions, the legacy provider must be activated in the openssl.cnf configuration file in order to use older ciphers like DES or Blowfish.
Additional Supplied Modules

Notes:

1. Any digest algorithm OpenSSL supports is automatically picked up. This is not possible with ciphers, which need to be supported explicitly.

F.33.6.2. NULL Handling

As is standard in SQL, all functions return NULL, if any of the arguments are NULL. This may create security risks on careless usage.

F.33.6.3. Security Limitations

All pgcrypto functions run inside the database server. That means that all the data and passwords move between pgcrypto and client applications in clear text. Thus you must:

1. Connect locally or use SSL connections.
2. Trust both system and database administrator.

If you cannot, then better do crypto inside client application.

The implementation does not resist side-channel attacks. For example, the time required for a pgcrypto decryption function to complete varies among ciphertexts of a given size.

F.33.6.4. Useful Reading

F.34. pg_freespacemap

The pg_freespacemap module provides a means for examining the free space map (FSM). It provides a function called pg_freespace, or two overloaded functions, to be precise. The functions show the value recorded in the free space map for a given page, or for all pages in the relation.

By default use is restricted to superusers and members of the pg_stat_scan_tables role. Access may be granted to others using GRANT.

F.34.1. Functions

pg_freespace(rel regclass IN, blkno bigint IN) returns int2

Returns the amount of free space on the page of the relation, specified by blkno, according to the FSM.

pg_freespace(rel regclass IN, blkno OUT bigint, avail OUT int2)

Displays the amount of free space on each page of the relation, according to the FSM. A set of (blkno bigint, avail int2) tuples is returned, one tuple for each page in the relation.

The values stored in the free space map are not exact. They're rounded to precision of 1/256th of BLCKSZ (32 bytes with default BLCKSZ), and they're not kept fully up-to-date as tuples are inserted and updated.

For indexes, what is tracked is entirely-unused pages, rather than free space within pages. Therefore, the values are not meaningful, just whether a page is full or empty.

F.34.2. Sample Output

postres=# SELECT * FROM pg_freespace('foo');
blkno | avail
-------+-------
 0 |    0
 1 |    0
 2 |    0
 3 |  32

F.35. pg_pathman

The **pg_pathman** is a Postgres Pro extension that provides an optimized partitioning solution for large and distributed databases. Using **pg_pathman**, you can:

- Partition large databases without downtime.
- Speed up query execution for partitioned tables.
- Manage existing partitions and add new partitions on the fly.
- Add foreign tables as partitions.
- Join partitioned tables for read and write operations.

The extension is compatible with Postgres Pro 9.5 or higher.

F.35.1. Installation and Setup

The **pg_pathman** extension is included into the Postgres Pro. Once you have Postgres Pro installed, complete the following steps to enable **pg_pathman**:

1. Add **pg_pathman** to the `shared_preload_libraries` variable in the `postgresql.conf` file:

   ```
   shared_preload_libraries = 'pg_pathman'
   ```
pg_pathman may have conflicts with other extensions that use the same hook functions. For example, pg_pathman may interfere with the pg_stat_statements extension as they both use ProcessUtility_hook. To avoid such issues, pg_pathman must always be the last in the list of libraries: shared_preload_libraries = 'pg_stat_statements, pg_pathman'.

2. Restart the Postgres Pro instance for the settings to take effect.

3. Create the pg_pathman extension as follows:

   ```
   CREATE SCHEMA pathman;
   GRANT USAGE ON SCHEMA pathman TO PUBLIC;
   CREATE EXTENSION pg_pathman WITH SCHEMA pathman;
   ```

Important
To ensure that your calls to pg_pathman's functions are always secure against search_path-based attacks (see CREATE EXTENSION for details), install it only into a clean schema where nobody except superusers has the CREATE privilege for database objects.

Once pg_pathman is enabled, you can start partitioning tables.

Note
During installation, pg_pathman creates a few RLS policies to restrict access to its own tables. Postgres Pro core, however, does not support dump/restore of databases where extensions issuing CREATE POLICY statements are installed. Therefore, when restoring a dump of a database where pg_pathman is installed, you will get error messages such as:

```
ERROR: policy "allow_select" for table "pathman_config" already exists
```

Ignore them since they do not affect whether the data being restored is complete.

Tip
You can also build pg_pathman from source code by executing the following command in the pg_pathman directory:

```
make install USE_PGXS=1
```

When this operation is complete, follow the steps described above to complete the setup.

In addition, do not forget to set the PG_CONFIG variable if you want to test pg_pathman on a custom build of Postgres Pro. For details, see Building and Installing PostgreSQL Extension Modules.

You can toggle pg_pathman or its specific custom nodes on and off using GUC variables. For details, see Section F.35.5.1.

If you want to permanently disable pg_pathman for a previously partitioned table, use the disable_pathman_for() function:

```
SELECT disable_pathman_for('range_rel');
```
All sections and data will remain unchanged and will be handled by the standard Postgres Pro inheritance mechanism.

**F.35.1.1. Updating pg_pathman**

If you already have a previous version of pg_pathman installed, complete the following steps to upgrade to a newer version:

1. Install Postgres Pro.
2. Restart your Postgres Pro cluster.
3. If you are running a previous major version of pg_pathman (the second digit in the version number is different), complete the update as follows:

   ```sql
   ALTER EXTENSION pg_pathman UPDATE TO version;
   SET pg_pathman.enable = t;
   ```

   where `version` is the pg_pathman major version number, such as 1.5.

   You can check the current pg_pathman version by running the `pathman_version()` function.

**F.35.2. Usage**

Choosing Partitioning Strategies

Running Non-Blocking Data Migration

Partitioning by a Single Expression

Partitioning by Composite Key

Running Multilevel Partitioning

Managing Partitions

As your database grows, indexing mechanisms may become inefficient and cause high latency as you run queries. To improve performance, ensure scalability, and optimize database administration processes you can use partitioning — splitting a large table into smaller pieces, with each row moved to a single partition according to the partitioning key.

Traditionally, Postgres Pro has supported partitioning via table inheritance, with each partition created as a child table with a CHECK constraint. In Postgres Pro 10, support for declarative partitioning was added, which also relies on inheritance. With these approaches, the query planner has to perform an exhaustive search and check constraints on each partition to build a query plan, which may slow down queries for tables with a large number of partitions. The pg_pathman extension uses an optimized planning algorithms and partitioning functions based on the internal structure of the partitioned tables, which allows to achieve better performance results. For details on pg_pathman implementation specifics, see Section F.35.4.

**F.35.2.1. Choosing Partitioning Strategies**

The pg_pathman extension supports the following partitioning strategies:

- Hash — maps rows to partitions using a generic hash function. Choose this strategy if most of your queries will be of the exact-match type.
- Range — maps rows to partitions based on partitioning key ranges assigned to each partition. Choose this strategy if your database contains numeric data that you are likely to query or manage by ranges. For example, you may want to query historical data by years, or review experiment results by specific numeric ranges. To achieve performance gains, pg_pathman uses the binary search algorithm.
By default, pg_pathman migrates all data from the parent table to the newly created partitions at once (blocking partitioning). This approach enables you to restructure the table in a single transaction, but may cause downtime if you have a lot of data. If it is critical to avoid downtime, you can use concurrent partitioning. In this case, pg_pathman writes all the updates to the newly created partitions, but keeps the original data in the parent table until you explicitly migrate it. This enables you to partition large databases without downtime, as you can choose convenient time for migration and copy data in small batches without blocking other transactions. For details on concurrent partitioning, see Section F.35.2.2.

F.35.2.1.1. Setting up Hash Partitioning

To perform hash partitioning with pg_pathman, run the create_hash_partitions() function:

create_hash_partitions(parent_relid REGCLASS, 
expression TEXT, 
partitions_count INTEGER, 
partition_data BOOLEAN DEFAULT TRUE, 
partition_names TEXT[], 
tablespaces TEXT[])

The pg_pathman module creates the specified number of partitions based on the hash function. Optionally, you can specify partition names and tablespaces by setting partition_names and tablespaces options, respectively.

You cannot add or remove partitions after the parent table is split. If required, you can replace the specified partition with another table:

replace_hash_partition(old_partition REGCLASS, 
new_partition REGCLASS, 
lock_parent BOOL DEFAULT TRUE)

When set to true, lock_parent parameter will prevent any INSERT/UPDATE/ALTER TABLE queries to parent table.

If you omit the optional partition_data parameter or set it to true, all the data from the parent table gets migrated to partitions. The pg_pathman module blocks the table for other transactions until data migration completes. To avoid downtime, you can set the partition_data parameter to false and later use the partition_table_concurrently() function to migrate your data to partitions without blocking other queries. For details, see the Section F.35.2.2.

F.35.2.1.2. Setting up Range Partitioning

The pg_pathman module provides the create_range_partitions() for range partitioning. This function creates partitions based on the specified interval and the initial partitioning key value. New partitions are created automatically when you insert data outside of the already covered range.

create_range_partitions(parent_relid REGCLASS, 
expression TEXT, 
start_value ANYELEMENT, 
p_interval ANYELEMENT | INTERVAL, 
p_count INTEGER DEFAULT NULL, 
partition_data BOOLEAN DEFAULT TRUE)

The pg_pathman module creates partitions based on the specified parameters. If you omit the optional p_count parameter, pg_pathman calculates the required number of partitions based on the specified start value and interval. If you insert new data outside of the existing partition range, pg_pathman creates new partitions automatically, keeping the specified interval. This approach ensures that all partitions are of the same size, which can improve query performance and facilitate database management.

Alternatively, you can specify an array defining the bounds of partitions to be created using the bounds parameter:

create_range_partitions(parent_relid REGCLASS, 
expression TEXT, 
start_value ANYELEMENT, 
p_interval ANYELEMENT | INTERVAL, 
p_count INTEGER DEFAULT NULL, 
partition_data BOOLEAN DEFAULT TRUE, 
bounds ANYELEMENT[])

2351
expression TEXT,
bounds ANYARRAY,
partition_names TEXT[] DEFAULT NULL,
tablespace TEXT[] DEFAULT NULL,
partition_data BOOLEAN DEFAULT TRUE)

If required, you can also use partition management functions to add partitions manually. For example, if there is a gap between the created partitions, pg_pathman cannot fill it with a new partition in an automated mode.

By default, all the data from the parent table gets migrated to the specified number of partitions. The pg_pathman module blocks the table for other transactions until data migration completes. To avoid downtime, you can set the partition_data parameter to false and later use the partition_table_concurrently() function to migrate your data to partitions without blocking other queries. For details, see the Section F.35.2.2.

### F.35.2.2. Running Non-Blocking Data Migration

If it is critical to avoid downtime, you can perform concurrent partitioning by setting the partition_data parameter of the partitioning function to false. In this case, pg_pathman creates empty partitions, keeping all the original data in the parent table. At the same time, all the database updates are written to the newly created partitions. You can later migrate the original data to partitions without blocking other queries using the partition_table_concurrently() function:

```sql
partition_table_concurrently(relation REGCLASS,
batch_size INTEGER DEFAULT 1000,
sleep_time FLOAT8 DEFAULT 1.0)
```

where:

- relation is the parent table.
- batch_size is the number of rows to copy from the parent table to partitions at a time. You can set this parameter to any integer value from 1 to 10000.
- sleep_time is the time interval between migration attempts, in seconds.

The pg_pathman module starts a background worker to move the data from the parent table to partitions in small batches of the specified batch_size. If one or more rows in the batch are locked by other queries, pg_pathman waits for the specified sleep_time and tries again, up to 60 times. You can monitor the migration process in the pathman_concurrent_part_tasks view that shows the number of rows migrated so far:

```
[user]postgres: select * from pathman_concurrent_part_tasks ;
 userid | pid  | dbid | relid | processed | status
--------+-------+-------+-------+-----------+---------
 user   | 20012 | 12413 | test  |    334000 | working
(1 row)
```

If you need to stop data migration, run the stop_concurrent_part_task() function at any time:

```sql
SELECT stop_concurrent_part_task(relation REGCLASS);
```

pg_pathman completes the migration of the current batch and terminates the migration process.

**Tip**

When pg_pathman migrates all the data from the parent table, you can exclude the parent table from the query plan. See the set_enable_parent() function description for details.
Additional Supplied Modules

F.35.2.3. Partitioning by a Single Expression
For both range and hash partitioning strategies, pg_pathman supports partitioning by expression that
returns a single scalar value. The partitioning expression can reference a table column, as well as
calculate the partitioning key based on one or more column values.

Tip
If you would like to partition a table by a tuple, see Section F.35.2.4.
To partition a table by expression, use pg_pathman partitioning functions. The partitioning expression
must satisfy the following conditions:
•
•
•
•
•

Expression must reference at least one column of the partitioned table.
All referenced columns must be marked as NOT NULL.
Expression cannot reference system attributes, such as oid, xmin, xmax, etc.
Expression cannot include subqueries.
All functions used by expression must be marked as IMMUTABLE.

As the expression can return a value of virtually any type, make sure to convert it to the type you need
for partitioning.
To access a partition, you must use the exact expression used for partitioning. Otherwise, pg_pathman
cannot optimize the query. You can view the partitioning expression for each partitioned table in the
pathman_config table.
F.35.2.3.1. Examples

Suppose you have the test table that stores some jsonb data:
CREATE TABLE test(col jsonb NOT NULL);
INSERT INTO test
SELECT format('{"key": %s, "date": "%s", "value": "%s"}',
i, current_date, md5(i::text))::jsonb
FROM generate_series(1, 10000 * 10) as g(i);
To partition this data by range of the key value, you need to extract this value from the jsonb object and
convert it to a numeric type, such as bigint:
SELECT create_range_partitions('test', '(col->>''key'')::bigint', 1, 10000, 10);
pg_pathman splits the parent table into ten partitions, with each partition storing 10000 rows:
SELECT * FROM pathman_partition_list;
parent | partition | parttype |
expr
| range_min |
range_max
--------+-----------+----------+---------------------------------+----------+----------test
| test_1
|
2 | ((col ->> 'key'::text))::bigint | 1
|
test
| test_2
|
2 | ((col ->> 'key'::text))::bigint | 10001
|
test
| test_3
|
2 | ((col ->> 'key'::text))::bigint | 20001
|
test
| test_4
|
2 | ((col ->> 'key'::text))::bigint | 30001
|
test
| test_5
|
2 | ((col ->> 'key'::text))::bigint | 40001
|

F.35.2.4. Partitioning by Composite Key

Using pg_pathman, you can also perform range partitioning by composite key. A composite key consists of two or more comma-separated values, which can be columns or expressions extracting the values from the table. The expressions defining the composite key must satisfy the conditions described in Section F.35.2.3.

Although pg_pathman does not support automatic partition creation by composite key, you can add partitions using the `add_range_partition()` function. A typical workflow is as follows:

1. Enable automatic partition naming for your table by running the `create_naming_sequence()` function.
2. Create a composite partitioning key.
3. Register a table you are going to partition with pg_pathman using the `add_to_pathman_config()` function.
4. Add a partition based on the defined composite partitioning key using the `add_range_partition()` function.

F.35.2.4.1. Examples

Suppose you have the `test` table that stores some temporal data:

```
CREATE TABLE test (logdate date NOT NULL, comment text);
```

To partition this data by month and year, you have to create a composite key:

```
CREATE TYPE test_key AS (year float8, month float8);
```

To enable automatic partition naming, run the `create_naming_sequence()` function passing the table name as an argument:

```
SELECT create_naming_sequence('test');
```

Register the `test` table with pg_pathman, specifying the partitioning key you are going to use:

```
SELECT add_to_pathman_config('test',
    '{ extract(year from logdate),
      extract(month from logdate) }::test_key',
    NULL);
```

Create a partition that includes all the data in the range of ten years, starting from January of the current year:

```
SELECT add_range_partition('test',
    (extract(year from current_date), 1)::test_key,
    (extract(year from current_date + '10 years'::interval),
     1)::test_key);
```

F.35.2.5. Running Multilevel Partitioning

pg_pathman supports multilevel partitioning for both hash and range partitioning strategies. You can use partitioning strategies in any combination: a hash- or range-partitioned table can be further partitioned by both hash or range.

To split an existing partition into several child ones, use the regular pg_pathman partitioning functions as explained in Section F.35.2.1, passing the name of the partition to be split as the `parent_relid` parameter. You can check the exact partition names in the `pathman_partition_list` view.

When opting for the range-range partitioning combination, you can either choose a different partitioning expression, or use the same expression as for the parent table. In the latter case, if the selected range is larger than that of the parent partition, only those child partitions that intersect with the parent range
Additional Supplied Modules

will be in use. Other child partitions will remain empty unless their parent is merged with an adjacent partition that covers at least a part of their range.

F.35.2.5.1. Examples

Suppose you have the journal table with some logs, which is partitioned by month:

```sql
-- create an empty table
CREATE TABLE journal (
  id SERIAL,
  dt TIMESTAMP NOT NULL,
  level INTEGER,
  msg TEXT);

-- generate some log data into the table
INSERT INTO journal (dt, level, msg)
SELECT g, random() * 6, md5(g::text)
FROM generate_series('2015-01-01'::date, '2015-12-31'::date, '1 minute') as g;

-- partition the table by range
SELECT create_range_partitions('journal', 'dt', '2015-01-01'::date, '1 month'::interval);

If having smaller partitions makes more sense at some point, you can further split the partitions by hash or range. For example, to split the journal_1 partition into subpartitions by day, run:

```sql
SELECT create_range_partitions('journal_1', 'dt', '2015-01-01'::date, '1 day'::interval);
```

Similarly, you can use hash partitioning to create child partitions. For example, split the journal_2 partition into five partitions by hash using the id column as the partitioning key:

```sql
SELECT create_hash_partitions('journal_2', 'id', '5');
```

F.35.2.6. Managing Partitions

pg_pathman provides multiple functions for easy partition management. For details, see Section F.35.5.3.4.

F.35.3. Examples

F.35.3.1. Common Tips

- You can add partition column containing the names of the underlying partitions using the system attribute called tableoid:

  ```sql
  SELECT tableoid::regclass AS partition, * FROM partitioned_table;
  ```

- Though indices on a parent table are not particularly useful (since the parent table is supposed to be empty), they act as prototypes for indices on partitions. For each index on the parent table, pg_pathman creates a similar index on each partition.

- All running concurrent partitioning tasks can be listed using the pathman_concurrent_part_tasks view:

  ```sql
  SELECT * FROM pathman_concurrent_part_tasks;
  ```

- The pathman_partition_list in conjunction with drop_range_partition() can be used to drop range partitions in a more flexible way compared to DROP TABLE:

  ```sql
  ```
Additional Supplied Modules

```
SELECT drop_range_partition(partition, false) /* move data to parent */
FROM pathman_partition_list
WHERE parent = 'part_test'::regclass AND range_min::int < 500;
```

```
NOTICE: 1 rows copied from part_test_11
NOTICE: 100 rows copied from part_test_1
NOTICE: 100 rows copied from part_test_2
```

```
drop_range_partition
----------------------
dummy_test_11
dummy_test_1
dummy_test_2
(3 rows)
```

- You can turn foreign tables into partitions using the `attach_range_partition()` function. Rows that were meant to be inserted into the parent will be redirected to foreign partitions using `PartitionFilter`. By default, it is only allowed to insert rows into partitions provided by `postgres_fdw`. This setting is controlled by the `pg_pathman.insert_into_fdw` variable. You must have superuser rights to change this setting.

F.35.3.2. Hash Partitioning

Consider an example of hash partitioning. First create a table with an integer column:

```
CREATE TABLE items (
    id SERIAL PRIMARY KEY,
    name TEXT,
    code BIGINT);
```

```
INSERT INTO items (id, name, code)
SELECT g, md5(g::text), random() * 100000
FROM generate_series(1, 100000) as g;
```

Now run the `create_hash_partitions()` function with appropriate arguments:

```
SELECT create_hash_partitions('items', 'id', 100);
```

This will create new partitions and move the data from the parent table to partitions.

Here is an example of the query performing filtering by partitioning key:

```
SELECT * FROM items WHERE id = 1234;
```

```
id  |               name               | code
------+----------------------------------+------
1234 | 81dc9bdb52d04dc20036dbd8313ed055 | 1855
```

```
EXPLAIN SELECT * FROM items WHERE id = 1234;
QUERY PLAN
------------------------------------------------------------------------------------
Append (cost=0.28..8.29 rows=0 width=0)  ->  Index Scan using items_34_pkey on items_34  (cost=0.28..8.29 rows=0 width=0)
Index Cond: (id = 1234)
```

Notice that the `Append` node contains only one child scan, which corresponds to the `WHERE` clause.

**Important**

Pay attention to the fact that `pg_pathman` excludes the parent table from the query plan.

To access the parent table, use the `ONLY` modifier:
EXPLAIN SELECT * FROM ONLY items;
QUERY PLAN
------------------------------------------------------
Seq Scan on items  (cost=0.00..0.00 rows=1 width=45)

F.35.3.3. Range Partitioning

Consider an example of range partitioning. Let's create a table containing some dummy logs:

```sql
CREATE TABLE journal (id SERIAL, dt TIMESTAMP NOT NULL, level INTEGER, msg TEXT);
```

-- similar index will also be created for each partition
CREATE INDEX ON journal(dt);

-- generate some data
INSERT INTO journal (dt, level, msg) SELECT g, random() * 6, md5(g::text) FROM generate_series('2015-01-01'::date, '2015-12-31'::date, '1 minute') as g;

Run the create_range_partitions() function to create partitions so that each partition would contain the data for one day:

```sql
SELECT create_range_partitions('journal', 'dt', '2015-01-01'::date, '1 day'::interval);
```

It will create 364 partitions and move the data from the parent table to partitions.

New partitions are appended automatically by insert trigger, but it can be done manually with the following functions:

-- add new partition with specified range
SELECT add_range_partition('journal', '2016-01-01'::date, '2016-01-07'::date);

-- append new partition with default range
SELECT append_range_partition('journal');

The first one creates a partition with specified range. The second one creates a partition with default interval and appends it to the partition list. It is also possible to attach an existing table as partition. For example, we may want to attach an archive table (or even foreign table from another server) for some outdated data:

```sql
CREATE FOREIGN TABLE journal_archive (id INTEGER NOT NULL, dt TIMESTAMP NOT NULL, level INTEGER, msg TEXT)
SERVER archive_server;
```

SELECT attach_range_partition('journal', 'journal_archive', '2014-01-01'::date, '2015-01-01'::date);

**Important**

The attached table must have the same columns as the partitioned table, except for the dropped columns. The attached columns must have the same type, collation, and NOT NULL settings as the original columns.
Additional Supplied Modules

To merge two adjacent partitions, use the `merge_range_partitions()` function:

```
SELECT merge_range_partitions('journal_archive', 'journal_1');
```

To split partition by value, use the `split_range_partition()` function:

```
SELECT split_range_partition('journal_366', '2016-01-03'::date);
```

To detach partition, use the `detach_range_partition()` function:

```
SELECT detach_range_partition('journal_archive');
```

Here is an example of the query performing filtering by partitioning key:

```
SELECT * FROM journal WHERE dt >= '2015-06-01' AND dt < '2015-06-03';
```

<table>
<thead>
<tr>
<th>id</th>
<th>dt</th>
<th>level</th>
<th>msg</th>
</tr>
</thead>
<tbody>
<tr>
<td>217441</td>
<td>2015-06-01 00:00:00</td>

| -> Seq Scan on journal_152 (cost=0.00..29.40 rows=0 width=0)   |
| -> Seq Scan on journal_153 (cost=0.00..29.40 rows=0 width=0)   |
(3 rows)
```

F.35.4. Internals

`pg_pathman` stores partitioning configuration in the `pathman_config` table; each row contains a single entry for a partitioned table (relation name, partitioning column and its type). During the initialization stage the `pg_pathman` module caches some information about child partitions in the shared memory, which is used later for plan construction. Before a SELECT query is executed, `pg_pathman` traverses the condition tree in search of expressions like:

```
VARIABLE OP CONST
```

where `VARIABLE` is a partitioning key, `OP` is a comparison operator (supported operators are `=`, `<`, `<=`, `>`, `>=`), `CONST` is a scalar value. For example:

```
WHERE id = 150
```

Based on the partitioning type and condition's operator, `pg_pathman` searches for the corresponding partitions and builds the plan.

F.35.4.1. Custom Plan Nodes

`pg_pathman` provides a couple of custom plan nodes which aim to reduce execution time, namely:

- `RuntimeAppend` (overrides `Append` plan node)
- `RuntimeMergeAppend` (overrides `MergeAppend` plan node)
- `PartitionFilter` (drop-in replacement for INSERT triggers)
- `PartitionRouter` for cross-partition UPDATE queries instead of triggers

`PartitionFilter` acts as a proxy node for INSERT’s child scan, which means it can redirect output tuples to the corresponding partition:

```
EXPLAIN (COSTS OFF)
INSERT INTO partitioned_table
```
Additional Supplied Modules

```sql
SELECT generate_series(1, 10), random();
```

**QUERY PLAN**

```
Insert on partitioned_table
  -> Custom Scan (PartitionFilter)
     -> Subquery Scan on "*SELECT*
        -> Result
```

(4 rows)

**PartitionRouter** is another proxy node used in conjunction with **PartitionFilter** to enable cross-partition **UPDATE** operations, for example, when you update any column of a partitioning key.

**Important**

The **PartitionRouter** node transforms cross-partition **UPDATE** commands into **DELETE** + **INSERT**. On Postgres Pro versions prior to 11, this operation is unsafe as **pg_pathman** cannot determine whether the updated row has been deleted or moved to another partition.

By default, **PartitionRouter** is disabled to avoid undesirable side effects. To enable this node, set the `pg_pathman.enable_partitionrouter` to on.

```sql
EXPLAIN (COSTS OFF)
UPDATE partitioned_table
SET value = value + 1 WHERE value = 2;
```

**QUERY PLAN**

```
Update on partitioned_table_0
  -> Custom Scan (PartitionRouter)
     -> Custom Scan (PartitionFilter)
        -> Seq Scan on partitioned_table_0
            Filter: (value = 2)
```

(5 rows)

**RuntimeAppend** and **RuntimeMergeAppend** have much in common: they come in handy in a case when **WHERE** condition takes form of:

```
VARIABLE OP PARAM
```

This kind of expressions can no longer be optimized at planning time since the parameter's value is not known until the execution stage takes place. The problem can be solved by embedding the **WHERE condition analysis routine** into the original **Append**'s code, thus making it pick only required scans out of a whole bunch of planned partition scans. This effectively boils down to creation of a custom node capable of performing such a check.

There are at least several cases that demonstrate usefulness of these nodes:

```sql
/* create table we're going to partition */
CREATE TABLE partitioned_table(id INT NOT NULL, payload REAL);

/* insert some data */
INSERT INTO partitioned_table
SELECT generate_series(1, 1000), random();

/* perform partitioning */
SELECT create_hash_partitions('partitioned_table', 'id', 100);

/* create ordinary table */
CREATE TABLE some_table AS SELECT generate_series(1, 100) AS VAL;
```
• id = (select ... limit 1)

EXPLAIN (COSTS OFF, ANALYZE) SELECT * FROM partitioned_table
WHERE id = (SELECT * FROM some_table LIMIT 1);

QUERY PLAN

Custom Scan (RuntimeAppend) (actual time=0.030..0.033 rows=1 loops=1)
  InitPlan 1 (returns $0)
    -> Limit (actual time=0.011..0.011 rows=1 loops=1)
      -> Seq Scan on some_table (actual time=0.010..0.010 rows=1 loops=1)
      -> Seq Scan on partitioned_table_70 partitioned_table (actual time=0.004..0.006 rows=1 loops=1)
        Filter: (id = $0)
        Rows Removed by Filter: 9

Planning time: 1.131 ms
Execution time: 0.075 ms
(9 rows)

/* disable RuntimeAppend node */
SET pg_pathman.enable_runtimeappend = f;

EXPLAIN (COSTS OFF, ANALYZE) SELECT * FROM partitioned_table
WHERE id = (SELECT * FROM some_table LIMIT 1);

QUERY PLAN

Append (actual time=0.196..0.274 rows=1 loops=1)
  InitPlan 1 (returns $0)
    -> Limit (actual time=0.005..0.005 rows=1 loops=1)
      -> Seq Scan on some_table (actual time=0.003..0.003 rows=1 loops=1)
      -> Custom Scan (RuntimeAppend) (actual time=0.002..0.004 rows=1 loops=1)
        -> Seq Scan on partitioned_table_70 partitioned_table (actual time=0.001..0.001 rows=10 loops=1)
        -> Seq Scan on partitioned_table_26 partitioned_table (actual time=0.002..0.003 rows=9 loops=1)
        -> Seq Scan on partitioned_table_27 partitioned_table (actual time=0.001..0.002 rows=20 loops=1)
        -> Seq Scan on partitioned_table_63 partitioned_table (actual time=0.001..0.002 rows=9 loops=1)

Planning time: 1.140 ms
Execution time: 0.855 ms
(306 rows)

• id = ANY (select ...)

EXPLAIN (COSTS OFF, ANALYZE) SELECT * FROM partitioned_table
WHERE id = any (SELECT * FROM some_table limit 4);

QUERY PLAN

Nested Loop (actual time=0.025..0.060 rows=4 loops=1)
  -> Limit (actual time=0.009..0.011 rows=4 loops=1)
    -> Seq Scan on some_table (actual time=0.008..0.010 rows=4 loops=1)
    -> Custom Scan (RuntimeAppend) (actual time=0.002..0.004 rows=1 loops=4)
      -> Seq Scan on partitioned_table_70 partitioned_table (actual time=0.001..0.001 rows=10 loops=1)
      -> Seq Scan on partitioned_table_26 partitioned_table (actual time=0.002..0.003 rows=9 loops=1)
      -> Seq Scan on partitioned_table_27 partitioned_table (actual time=0.001..0.002 rows=20 loops=1)
      -> Seq Scan on partitioned_table_63 partitioned_table (actual time=0.001..0.002 rows=9 loops=1)

Planning time: 0.771 ms
Additional Supplied Modules

Execution time: 0.101 ms
(10 rows)

/* disable RuntimeAppend node */
SET pg_pathman.enable_runtimeappend = f;

EXPLAIN (COSTS OFF, ANALYZE) SELECT * FROM partitioned_table
WHERE id = any (SELECT * FROM some_table limit 4);

QUERY PLAN

```
Nested Loop Semi Join (actual time=0.531..1.526 rows=4 loops=1)
  Join Filter: (partitioned_table.id = some_table.val)
  Rows Removed by Join Filter: 3990
  -> Append (actual time=0.190..0.470 rows=1000 loops=1)
    -> Seq Scan on partitioned_table (actual time=0.187..0.187 rows=0 loops=1)
    -> Seq Scan on partitioned_table_0 (actual time=0.002..0.004 rows=6 loops=1)
    -> Seq Scan on partitioned_table_1 (actual time=0.001..0.001 rows=5 loops=1)
    -> Seq Scan on partitioned_table_2 (actual time=0.002..0.004 rows=14 loops=1)
  ... /* 96 scans follow */
  -> Materialize (actual time=0.000..0.000 rows=4 loops=1000)
    -> Limit (actual time=0.005..0.006 rows=4 loops=1)
      -> Seq Scan on some_table (actual time=0.003..0.004 rows=4 loops=1)
```

Planning time: 2.169 ms
Execution time: 2.059 ms
(110 rows)

- NestLoop involving a partitioned table, which is omitted since it's occasionally shown above.
To learn more about custom nodes, see Alexander Korotkov's blog.

**F.35.5. Reference**

**F.35.5.1. GUC Variables**

There are several user-accessible GUC variables designed to toggle pg_pathman or its specific custom nodes on and off.

- pg_pathman.enable — enable/disable the pg_pathman module.
  
  Default: on

- pg_pathman.enable_runtimeappend — toggle the RuntimeAppend custom node on/off.

  Default: on

- pg_pathman.enable_runtimemergeappend — toggle the RuntimeMergeAppend custom node on/off.

  Default: on

- pg_pathman.enable_partitionfilter — toggle the PartitionFilter custom node on/off to enable/disable cross-partition INSERT operations.

  Default: on

- pg_pathman.enable_partitionrouter — toggle the PartitionRouter custom node on/off to enable/disable cross-partition UPDATE operations.

  Default: off

- pg_pathman.enable_auto_partition — toggle automatic partition creation on/off (per session).

  Default: on
• `pg_pathman.enable_bounds_cache` — toggle bounds cache on/off.
  Default: on

• `pg_pathman.insert_into_fdw` — allow `INSERT` operations into various foreign-data wrappers.
  Possible values: disabled, postgres, and any_fdw.
  Default: postgres

• `pg_pathman.override_copy` — toggle `COPY` statement hooking on/off.
  Default: on

F.35.5.2. Views and Tables

F.35.5.2.1. pathman_config

This table stores the list of partitioned tables. This is the main configuration storage.

```sql
CREATE TABLE IF NOT EXISTS pathman_config (  
  partrel REGCLASS NOT NULL PRIMARY KEY,  
  attname TEXT NOT NULL,  
  parttype INTEGER NOT NULL,  
  range_interval TEXT);
```

F.35.5.2.2. pathman_config_params

This table stores optional parameters that override standard `pg_pathman` behavior.

```sql
CREATE TABLE IF NOT EXISTS pathman_config_params (  
  partrel REGCLASS NOT NULL PRIMARY KEY,  
  enable_parent BOOLEAN NOT NULL DEFAULT TRUE,  
  auto BOOLEAN NOT NULL DEFAULT TRUE,  
  init_callback REGPROCEDURE NOT NULL DEFAULT 0,  
  spawn_using_bgw BOOLEAN NOT NULL DEFAULT FALSE);
```

F.35.5.2.3. pathman_concurrent_part_tasks

This view lists all currently running concurrent partitioning tasks.

```sql
-- helper SRF function  
CREATE OR REPLACE FUNCTION show_concurrent_part_tasks()  
RETURNS TABLE (  
  userid REGROLE,  
  pid INT,  
  dbid OID,  
  relid REGCLASS,  
  processed INT,  
  status TEXT)  
AS 'pg_pathman', 'show_concurrent_part_tasks_internal'  
LANGUAGE C STRICT;
```

CREATE OR REPLACE VIEW pathman_concurrent_part_tasks  
AS SELECT * FROM show_concurrent_part_tasks();

F.35.5.2.4. pathman_partition_list

This view lists all existing partitions, as well as their parents and range boundaries (NULL for hash partitions).

```sql
-- helper SRF function  
CREATE OR REPLACE FUNCTION show_partition_list()  
RETURNS TABLE (  
  parent REGCLASS,  
  partition REGCLASS,
```

2362
Additional Supplied Modules

```
partype   INT4,
expr       TEXT,
range_min  TEXT,
range_max  TEXT)
AS 'pg_pathman', 'show_partition_list_internal'
LANGUAGE C STRICT;
```

CREATE OR REPLACE VIEW pathman_partition_list
AS SELECT * FROM show_partition_list();

F.35.5.3. Functions

F.35.5.3.1. Partitioning Functions

```
create_hash_partitions(parent_relid REGCLASS,
expression TEXT,
partitions_count INTEGER,
partition_data BOOLEAN DEFAULT TRUE,
partition_names TEXT[] DEFAULT NULL,
tablespaces TEXT[] DEFAULT NULL)
```

Performs hash partitioning for relation by integer key expression. The partitions_count parameter specifies the number of partitions to create; it cannot be changed afterwards. If partition_data is true, all the data will be automatically migrated from the parent table to partitions. Note that data migration may take a while to finish and the table will be locked until transaction commits. See partition_table_concurrently() for a lock-free way to migrate data. Partition creation callback is invoked for each partition if set beforehand (see set_init_callback()).

```
create_range_partitions(relation REGCLASS,
expression TEXT,
start_value ANYELEMENT,
p_interval ANYELEMENT,
p_count INTEGER DEFAULT NULL,
partition_data BOOLEAN DEFAULT TRUE)
```

Perform range partitioning for relation by partitioning key defined by expression. The start_value argument specifies the initial value, p_interval sets the default range for automatically created partitions or partitions created with append_range_partition() or prepend_range_partition(). If p_interval is set to NULL, automatic partition creation is disabled. p_count is the number of premade partitions. If p_count is not set, then pg_pathman tries to determine the number of partitions based on the expression value. The bounds array defines the bounds for partitions to be created. You can build this array using the generate_range_bounds() function. Partition creation callback is invoked for each partition if set beforehand.

F.35.5.3.2. Data Migration Functions

```
partition_table_concurrently(relation REGCLASS,
2363
```
Additional Supplied Modules

batch_size INTEGER DEFAULT 1000,
sleep_time FLOAT8 DEFAULT 1.0)

Starts a background worker to move data from parent table to partitions. The worker utilizes short
transactions to copy small batches of data (up to 10K rows per transaction) and thus doesn't significantly
interfere with user's activity.

stop_concurrent_part_task(relation REGCLASS)

Stops a background worker performing a concurrent partitioning task. Note: worker will exit after it
finishes relocating a current batch.

F.35.5.3.3. Triggers

Triggers are no longer required for INSERT and cross-partition UPDATE operations. However, user-
supplied triggers are supported:

• Each inserted row results in execution of BEFORE/AFTER INSERT trigger functions of a
corresponding partition.
• Each updated row results in execution of BEFORE/AFTER UPDATE trigger functions of a
corresponding partition.
• Each moved row (cross-partition update) results in execution of BEFORE UPDATE + BEFORE/
AFTER DELETE + BEFORE/AFTER INSERT trigger functions of corresponding partitions.

F.35.5.3.4. Partition Management Functions

replace_hash_partition(old_partition      REGCLASS,
new_partition       REGCLASS,
lock_parent         BOOLEAN DEFAULT TRUE)

Replaces the specified partition of hash-partitioned table with another table. When set to true, the
lock_parent parameter prevents any INSERT/UPDATE/ALTER TABLE queries to the parent table.

split_range_partition(partition_relid  REGCLASS,
split_value      ANYELEMENT,
partition_name   TEXT DEFAULT NULL,
tablespace       TEXT DEFAULT NULL)

Split range partition in two by value, with the specified value included into the second partition.
Partition creation callback is invoked for a new partition if available.

merge_range_partitions(variadic partitions REGCLASS[])

Merge several adjacent range partitions. Partitions are automatically ordered by increasing bounds. All
the data will be accumulated in the first partition, while other merged partitions are removed. If the
remaining partition has any child partitions, new child partitions for the merged data will be created as
required using the same partitioning expression.

append_range_partition(parent_relid   REGCLASS,
partition_name TEXT DEFAULT NULL,
tablespace     TEXT DEFAULT NULL)

Append new range partition with pathman_config.range_interval as interval.

prepend_range_partition(parent_relid   REGCLASS,
partition_name TEXT DEFAULT NULL,
tablespace     TEXT DEFAULT NULL)

Prepend new range partition with pathman_config.range_interval as interval.

add_range_partition(parent_relid   REGCLASS,
start_value    ANYELEMENT,
Create a new range partition for relation with the specified range bounds. If the start_value or the end_value is NULL, the corresponding range bound will be infinite.

```
drop_range_partition(partition_relid TEXT, delete_data BOOLEAN DEFAULT TRUE)
```

Drop range partition and all of its data if delete_data is true.

```
attach_range_partition(parent_relid REGCLASS, partition_relid REGCLASS, start_value ANYELEMENT, end_value ANYELEMENT)
```

Attach partition to the existing range-partitioned relation. The attached table must have exactly the same structure as the parent table, including the dropped columns. Partition creation callback is invoked if set (see Section F.35.5.2.2).

```
detach_range_partition(partition_relid REGCLASS)
```

Detach partition from the existing range-partitioned relation.

```
disable_pathman_for(parent_relid REGCLASS)
```

Permanently disable pg_pathman partitioning mechanism for the specified parent table and remove the insert trigger if it exists. All partitions and data remain unchanged.

```
drop_partitions(parent_relid REGCLASS, delete_data BOOLEAN DEFAULT FALSE)
```

Drop partitions of the parent table (both foreign and local relations). If delete_data is false, the data is copied to the parent table first. Default is false.

### F.35.5.3.5. Additional Functions

```
pathman_version()
```

Returns the pg_pathman version number.

```
set_interval(relation REGCLASS, value ANYELEMENT)
```

Update range-partitioned table interval. Note that interval must not be negative and it must not be trivial, i.e. its value should be greater than zero for numeric types, at least 1 microsecond for timestamp and at least 1 day for date.

```
set_enable_parent(relation REGCLASS, value BOOLEAN)
```

Include/exclude parent table into/from query plan. In original Postgres Pro planner parent table is always included into query plan even if it’s empty, which can lead to additional overhead. You can use disable_parent() if you are never going to use parent table as a storage. Default value depends on the partition_data parameter specified during initial partitioning with the create_range_partitions() function. If the partition_data parameter was true, then all data have already been migrated to partitions and the parent table is disabled. Otherwise, it is enabled.

```
set_auto(relation REGCLASS, value BOOLEAN)
```

Enable/disable auto partition propagation (only for range partitioning). It is enabled by default.

```
set_init_callback(relation REGCLASS, callback REGPROCEDURE DEFAULT 0)
```

Set partition creation callback to be invoked for each attached or created partition (both hash and range). If callback is marked with SECURITY INVOKER, it is executed with the privileges of the user who produced a statement that has led to creation of a new partition. For example:
INSERT INTO partitioned_table VALUES (-5)

The callback must have the following signature: part_init_callback(args JSONB) RETURNS VOID. Parameter arg consists of several fields whose presence depends on partitioning type:

/* Range-partitioned table abc (child abc_4) */
{
  "parent": "abc",
  "parttype": "2",
  "partition": "abc_4",
  "range_max": "401",
  "range_min": "301"
}

/* Hash-partitioned table abc (child abc_0) */
{
  "parent": "abc",
  "parttype": "1",
  "partition": "abc_0"
}

set_spawn_using_bgw(relation REGCLASS, value BOOLEAN)

When inserting new data beyond the partitioning range, use SpawnPartitionsWorker to create new partitions in a separate transaction.

create_naming_sequence(parent_relid REGCLASS)

Enable automatic partition naming for the specified relation table. You must run this function when partitioning this table by composite key.

add_to_pathman_config(parent_relid REGCLASS, expression TEXT, range_interval TEXT)
add_to_pathman_config(parent_relid REGCLASS, expression TEXT)

Register the specified relation table with pg_pathman to enable partitioning by the provided expression. For range partitioning, the range_interval argument is mandatory. You can set it to NULL if you are going to add partition manually.

generate_range_bounds(p_start ANYELEMENT, p_interval INTERVAL, p_count INTEGER)
generate_range_bounds(p_start ANYELEMENT, p_interval ANYELEMENT, p_count INTEGER)

Build the bounds array that defines the bounds for partitions to be created. You can pass this array as an argument to the create_range_partitions() function.

- Ildar Musin
- Alexander Korotkov
- Dmitry Ivanov
F.36. pg_proaudit

The pg_proaudit extension enables detailed logging of various security events.

pg_proaudit works in parallel with the standard PostgreSQL logging solutions (logging collector) and does not depend on them. Security event log of the pg_proaudit extension is stored separately from the server log. At the Postgres Pro Standard startup, pg_proaudit launches a special background process to log security events.

Logging settings are stored in the pg_proaudit.conf configuration file located in the cluster data directory (PGDATA). It is a text file that can be edited directly using operating system facilities. To modify the file using SQL, you can use several pg_proaudit functions. The pg_proaudit_settings view displays the current pg_proaudit settings, even if they have not been saved into the pg_proaudit.conf file yet.

All the logged events belong to the following classes:

- DDL commands for creating, changing, and deleting DBMS objects (databases, tables, views, sequences, languages, functions)
- access control commands for database objects (GRANT, REVOKE)
- DML commands for access to database objects (INSERT, UPDATE, DELETE, SELECT, TRUNCATE for tables and/or views, EXECUTE for functions)
- database connection/disconnection events
- all commands executed by a particular user

Security events can be logged both in the centralized logging solution of the operating system (syslog) and in the standard file-system files. Event logs can be written both into the syslog and into the files simultaneously. Event log files are written in the CSV format. Each event is logged on a separate line that contains the following fields:

- date and time of the event
- username
- database name
- server process ID (PID)
- severity level: INFO or ERROR
- serial number of the command in a session
- subcommand number in complex commands (CREATE TABLE ... AS SELECT ...)
- operator name
- object type
- object name
- operator execution results: SUCCESS or FAILURE
- error message in case of FAILURE
- text of the SQL command
- parameters of the command (for example, for PREPARE)

You can define a directory to store security log files and set up log file rotation. pg_proaudit can switch to a new log file either after the specified time interval, or when the specified size of the log file is exceeded. This enables you to define a workflow for cleaning up security event logs.

Postgres Pro user with the SUPERUSER attribute should grant access to the pg_proaudit extension and security event log files only to the user with the information security administrator role.

F.36.1. Installation and Setup

The pg_proaudit extension is a built-in extension included into Postgres Pro Standard. To enable pg_proaudit, complete the following steps:

1. Add pg_proaudit to the shared_preload_libraries variable in the postgresql.conf file:

   shared_preload_libraries = 'pg_proaudit'
2. Reload the database server for the changes to take effect.

**Note**

To verify that the `pg_proaudit` library was installed correctly, you can run the following command:

```sql
SHOW shared_preload_libraries;
```

3. Create the `pg_proaudit` extension using the following query:

```sql
CREATE EXTENSION pg_proaudit;
```

The `pg_proaudit` extension adds several functions for managing the `pg_proaudit.conf` file, the `pg_proaudit_settings` view that displays the current `pg_proaudit` settings and event triggers. For convenience, the `pg_proaudit` extension should be created in each database for which you are going to log security events.

### F.36.2. Configuring Security Events to Log

To configure security event logging, `pg_proaudit` provides an SQL interface that consists of several functions and the `pg_proaudit_settings` view.

```sql
pg_proaudit_set_object(event_type  text, 
    object_type text)
pg_proaudit_set_object(event_type text, 
    object_oid  oid)
```

Enables logging for events with the specified parameters. When the `pg_proaudit_set_object()` function completes, security event logging starts immediately, but the `pg_proaudit.conf` file is not updated. To save the changes in the `pg_proaudit.conf` file, call the `pg_proaudit_save()` function.

**Arguments:**

- `event_type` — type of the event that needs to be logged, including SQL operator names, as well as `CONNECT` and `DISCONNECT` events. When set to `ALL`, enables logging for all events available for the specified object type. For example, for the `TABLE` object type, the `ALL` keyword enables logging for commands `SELECT`, `INSERT`, `UPDATE`, `DELETE`, `TRUNCATE`, as well as `CREATE`, `ALTER`, `DROP`. For the full list of possible `event_type` values, see Section F.36.3.1.
- `object_type` — type of the object for which security events need to be logged. For example, specify `FOREIGN TABLE` object type for the `SELECT` event to log all attempts to access foreign tables. Use the `NULL` value if `event_type` is set to `CONNECT`, `DISCONNECT`, `SET`, or `RESET`, and the `ROLE` value for all events that reference user actions, such as `CREATE USER` or `DROP USER`.
- `object_oid` — identifier of the object (OID) for which security events need to be logged.

```sql
pg_proaudit_set_role(event_type text, 
    role_oid oid)
```

Enables logging of events caused by the specified DBMS user. When the `pg_proaudit_set_role()` function completes, security event logging starts immediately, but the `pg_proaudit.conf` file is not updated. To save the changes in the `pg_proaudit.conf` file, call the `pg_proaudit_save()` function.

**Arguments:**

- `event_type` — type of the event that needs to be logged. When set to `ALL`, enables logging for all commands executed by the `role_oid` user. For the list of possible values, see Section F.36.3.1.
- `role_oid` — identifier of the user (OID) for which actions need to be logged.
Additional Supplied Modules

object_type text)
pg_proaudit_reset_object(event_type text,
                         object_oid oid)

Disables logging of events with specified parameters. To save the changes in the pg_proaudit.conf file, call the pg_proaudit_save() function.

Arguments:

• *event_type* — type of the event that needs to be logged, including SQL operator names, as well as CONNECT and DISCONNECT events. When set to ALL, enables logging for all events available for the specified object type. For example, for the table object type, the ALL keyword enables logging for commands SELECT, INSERT, UPDATE, DELETE, TRUNCATE, as well as CREATE, ALTER, DROP. For the full list of possible *event_type* values, see Section F.36.3.1.

• *object_type* — type of the object for which security events need to be logged. For example, specify FOREIGN TABLE object type for the SELECT event to log all attempts to access foreign tables. Use the NULL value if *event_type* is set to CONNECT, DISCONNECT, SET, or RESET, and the ROLE value for all events that reference user actions, such as CREATE USER or DROP USER.

• *object_oid* — identifier of the object (OID) for which security events need to be logged.

pg_proaudit_reset_role(event_type text,
                       role_oid   oid)

Disables logging of events caused by the specified DBMS user. To save information about the canceled events in the pg_proaudit.conf file, call the pg_proaudit_save() function.

Arguments:

• *event_type* — type of the event that needs to be logged. When set to ALL, enables logging for all commands executed by the *role_oid* user. For the list of possible values, see Section F.36.3.1.

• *role_oid* — identifier of the user (OID) for which actions need to be logged.

pg_proaudit_show()  
Returns logged events in a table view. This function is used by the pg_proaudit_settings view.

pg_proaudit_reload()  
Reads logging configuration from the pg_proaudit.conf file. You must call this function if the pg_proaudit.conf file was modified manually using the operating system facilities.

pg_proaudit_reset()  
Disables logging of all events. To save information about the canceled events in the pg_proaudit.conf file, call the pg_proaudit_save() function.

pg_proaudit_save()  
Saves logging settings from memory into the pg_proaudit.conf file. The pg_proaudit.conf file is located in the cluster data directory (PGDATA). You cannot change the pg_proaudit.conf file location.

F.36.3. pg_proaudit_settings View  
This view displays the current pg_proaudit settings, even if they have not been saved into the pg_proaudit.conf file yet. The pg_proaudit_settings view consists of the following columns:

• *db_name* (text) — name of the database for which to log security events.

• *event_type* (text) — event type to log.

• *object_type* — type of the object for which security events are to be logged.

• *object_name* (text) — name of the object for which security events are to be logged.

• *role_name* (text) — the role on behalf of which logged actions are performed.
F.36.3.1. Security Events

The `pg_proaudit` extension can log the following security events:

- CONNECT
- DISCONNECT
- ALTER AGGREGATE
- ALTER COLLATION
- ALTER CONVERSION
- ALTER DATABASE
- ALTER DEFAULT PRIVILEGES
- ALTER DOMAIN
- ALTER EVENT TRIGGER
- ALTER EXTENSION
- ALTER FOREIGN DATA WRAPPER
- ALTER FOREIGN TABLE
- ALTER FUNCTION
- ALTER INDEX
- ALTER LANGUAGE
- ALTER LARGE OBJECT
- ALTER MATERIALIZED VIEW
- ALTER OPERATOR
- ALTER OPERATOR CLASS
- ALTER OPERATOR FAMILY
- ALTER POLICY
- ALTER ROLE, ALTER USER, ALTER GROUP
- ALTER RULE
- ALTER SCHEMA
- ALTER SEQUENCE
- ALTER SERVER
- ALTER SYSTEM
- ALTER TABLE
- ALTER TABLESPACE
- ALTER TEXT SEARCH CONFIGURATION
- ALTER TEXT SEARCH DICTIONARY
- ALTER TEXT SEARCH PARSER
- ALTER TEXT SEARCH TEMPLATE
- ALTER TRIGGER
- ALTER TYPE
- ALTER USER MAPPING
- ALTER VIEW
- CLUSTER
- COMMENT
- COPY
- CREATE ACCESS METHOD
- CREATE AGGREGATE
- CREATE CAST
- CREATE COLLATION
- CREATE CONVERSION
- CREATE DATABASE
- CREATE DOMAIN
- CREATE EVENT TRIGGER
- CREATE EXTENSION
- CREATE FOREIGN DATA WRAPPER
- CREATE FOREIGN TABLE
- CREATE FUNCTION
- CREATE INDEX
- CREATE LANGUAGE
- CREATE MATERIALIZED VIEW
- CREATE OPERATOR
- CREATE OPERATOR CLASS
- CREATE OPERATOR FAMILY
- CREATE POLICY
- CREATE ROLE, CREATE USER, CREATE GROUP
- CREATE RULE
- CREATE SCHEMA
- CREATE SEQUENCE
- CREATE SERVER
- CREATE TABLE, CREATE TABLE AS, SELECT INTO
- CREATE TABLESPACE
- CREATE TEXT SEARCH CONFIGURATION
- CREATE TEXT SEARCH DICTIONARY
- CREATE TEXT SEARCH PARSER
- CREATE TEXT SEARCH TEMPLATE
- CREATE TRANSFORM
- CREATE TRIGGER
- CREATE TYPE
- CREATE USER MAPPING
- CREATE VIEW
- DELETE
- DO
- DROP ACCESS METHOD
- DROP AGGREGATE
- DROP CAST
- DROP COLLATION
- DROP CONVERSION
- DROP DATABASE
- DROP DOMAIN
- DROP EVENT TRIGGER
- DROP EXTENSION
- DROP FOREIGN DATA WRAPPER
- DROP FOREIGN TABLE
- DROP FUNCTION
- DROP INDEX
- DROP LANGUAGE
- DROP MATERIALIZED VIEW
- DROP OPERATOR
- DROP OPERATOR CLASS
- DROP OPERATOR FAMILY
- DROP OWNED
- DROP POLICY
- DROP ROLE, DROP USER, DROP GROUP
- DROP RULE
- DROP SCHEMA
- DROP SEQUENCE
- DROP SERVER
- DROP TABLE
- DROP TABLESPACE
- DROP TEXT SEARCH CONFIGURATION
- DROP TEXT SEARCH DICTIONARY
- DROP TEXT SEARCH PARSER
- DROP TEXT SEARCH TEMPLATE
F.36.4. Security Event Log Configuration Parameters

The `pg_proaudit` extension provides several configuration parameters for managing security event log files. These parameters can be set in the `postgresql.conf` configuration file, or with the help of the `ALTER SYSTEM` command. For the changes to take effect, call the `pg_reload_conf()` function or reload the database server.

- `pg_proaudit.log_destination (string)`
  Defines the method for logging security events. Possible values are:
  - `csvlog` — log security events in a CSV file.
  - `syslog` — log security events in syslog.
  You can specify one or more values separated by commas.

  Default: `csvlog`

- `pg_proaudit.log_catalog_access (boolean)`
  Specifies whether to log access to system catalog objects in the `pg_catalog` schema.

  Default: `off`

- `pg_proaudit.log_command_text (boolean)`
  Specifies whether to log the SQL command text for security events.

  Default: `on`

- `pg_proaudit.log_directory (string)`
  Specifies the path to the directory that stores CSV log files. This can be an absolute path, or a relative path to the cluster data directory (`PGDATA`). This parameter is used if `pg_proaudit.log_destination` contains the `csvlog` value.

  Default: `pg_proaudit`

- `pg_proaudit.log_filename (string)`
  Defines the filenames of the created security event log files. The filename template can contain %-escapes, similar to the ones listed in the `strftime` specification of the Open Group.
Additional Supplied Modules

(http://pubs.opengroup.org/onlinepubs/009695399/functions/strftime.html). This parameter is used if pg_proaudit.log_destination contains the csvlog value.

Default: postgresql-%Y-%m-%d_%H%M%S.log

pg_proaudit.log_rotation_size (integer)

Sets the maximum size of the CSV log file, in kilobytes. When this size is achieved, pg_proaudit creates a new file for logging security events. This parameter is used if pg_proaudit.log_destination contains the csvlog. If set to 0, disables size-based creation of new log files.

Default: 10MB

pg_proaudit.log_rotation_age (integer)

Sets the maximum lifetime of a log file, in minutes. After this timeframe has elapsed, pg_proaudit creates a new file for logging security events. This parameter is used if pg_proaudit.log_destination contains the csvlog. If set to 0, disables time-based creation of new log files.

Default: 1day

pg_proaudit.log_truncate_on_rotation (boolean)

Specifies whether to truncate log files when logging is switched to an existing log file. If set to off, pg_proaudit appends new log entries to the end of the file. This parameter is used if pg_proaudit.log_destination contains the csvlog value.

Default: off

pg_proaudit.syslog_facility (enum)

Specifies the logging category in syslog. This parameter is used if pg_proaudit.log_destination contains the syslog value. Possible values are: LOCAL0, LOCAL1, LOCAL2, LOCAL3, LOCAL4, LOCAL5, LOCAL6, LOCAL7.

Default: LOCAL0

pg_proaudit.syslog_ident (string)

Specifies the program name used to identify pg_proaudit messages in syslog logs.

Default: pg_proaudit

F.36.5. Viewing Security Event Log

Security event log files are text files that can be viewed by the operating system facilities. To access log files using SQL, you can use the file_fdw extension — a foreign data wrapper for accessing files on the database server. To use this method, complete the following steps:

1. Install the file_fdw and create an external server:

   CREATE EXTENSION file_fdw;
   CREATE SERVER pg_proauditlog FOREIGN DATA WRAPPER file_fdw;

2. Create a foreign table, specifying the columns and the absolute path to the log file. The actual log file location is determined by the pg_proaudit.log_directory and pg_proaudit.log_filename parameters.

   CREATE FOREIGN TABLE pg_proaudit_log
   ( log_time timestamp(3) with time zone, role_name text,
Additional Supplied Modules

database_name text,
session_pid text,
error_severity text,
session_line_num bigint,
session_line_subcommand_num bigint,
event_type text,
object_type text,
object_name text,
status text,
error_message text,
query_text text,
query_args text )

SERVER pg_proauditlog
OPTIONS (filename 'absolute_file_path_to_log_file.csv', FORMAT 'csv');

Make sure that the `pg_proaudit.log_destination` parameter contains the `csvlog` value, which enables writing security event logs to CSV files.

F.36.6. Examples

As an example, let's set up logging for the following security events:

- connections/disconnections to the `postgres` database
- all actions of the `postgres` user
- creating, updating, and deleting any tables
- all operations on the `app_table` table that belongs to the `public` schema

All events must be logged in the CSV format and stored for a week. It is required to set up SQL access to the security event log. To complete the scenario, do the following:

In psql, check that the preliminary setup of the `pg_proaudit` extension is complete in the `postgres` database:

SHOW shared_preload_libraries;

shared_preload_libraries
--------------------------
pg_proaudit

\dx pg_proaudit

List of installed extensions
Name    | Version | Schema | Description
------------------------+---------+--------+---------------------------------
pg_proaudit | 1.0     | public | provides auditing functionality

Add the following lines to the `postgresql.conf` configuration file:

```
pg_proaudit.log_destination = 'csvlog'
pg_proaudit.log_directory = 'audit'
pg_proaudit.log_filename = 'audit-%u.csv'
pg_proaudit.log_rotation_age = 1440
pg_proaudit.log_rotation_size = 0
pg_proaudit.log_truncate_on_rotation = on
pg_proaudit.log_command_text = on
```

For the changes to take effect, run the following query:

```
SELECT pg_reload_conf();
```

Check that the following parameters are set as expected:

```
SHOW pg_proaudit.log_destination;
SHOW pg_proaudit.log_directory;
```
SHOW pg_proaudit.log_filename;
SHOW pg_proaudit.log_rotation_age;
SHOW pg_proaudit.log_rotation_size;
SHOW pg_proaudit.log_truncate_on_rotation;
SHOW pg_proaudit.log_command_text;

Suppose your PGDATA environment variable points to the cluster data directory. Since the pg_proaudit.log_directory defines a relative path to the log files, they will be located in the $PGDATA/audit directory. Let's create an empty file for each day of the week and make them available to their owner only:

touch $PGDATA/audit/audit-1.csv
touch $PGDATA/audit/audit-2.csv
touch $PGDATA/audit/audit-3.csv
touch $PGDATA/audit/audit-4.csv
touch $PGDATA/audit/audit-5.csv
touch $PGDATA/audit/audit-6.csv
touch $PGDATA/audit/audit-7.csv
chmod 600 $PGDATA/audit/audit-*.csv

Create a table for reading log entries:

CREATE TABLE pg_proaudit_log (  
  log_time timestamp(3) with time zone,  
  role_name text,  
  database_name text,  
  session_pid text,  
  error_severity text,  
  session_line_num bigint,  
  session_line_subcommand_num bigint,  
  event_type text,  
  object_type text,  
  object_name text,  
  status text,  
  error_message text,  
  query_text text,  
  query_args text  
);

Install the file_fdw extension and create an external server:

CREATE EXTENSION file_fdw;
CREATE SERVER pg_proauditlog FOREIGN DATA WRAPPER file_fdw;

Now let's create seven child foreign tables for the pg_proaudit_log table, for each day of the week:

CREATE FOREIGN TABLE pg_proaudit_log_1 () INHERITS (pg_proaudit_log) SERVER pg_proauditlog  
  OPTIONS (filename 'path_to_PGDATA/audit/audit-1.csv', FORMAT 'csv');
CREATE FOREIGN TABLE pg_proaudit_log_2 () INHERITS (pg_proaudit_log) SERVER pg_proauditlog  
  OPTIONS (filename 'path_to_PGDATA/audit/audit-2.csv', FORMAT 'csv');
CREATE FOREIGN TABLE pg_proaudit_log_3 () INHERITS (pg_proaudit_log) SERVER pg_proauditlog  
  OPTIONS (filename 'path_to_PGDATA/audit/audit-3.csv', FORMAT 'csv');
CREATE FOREIGN TABLE pg_proaudit_log_4 () INHERITS (pg_proaudit_log) SERVER pg_proauditlog  
  OPTIONS (filename 'path_to_PGDATA/audit/audit-4.csv', FORMAT 'csv');
CREATE FOREIGN TABLE pg_proaudit_log_5 () INHERITS (pg_proaudit_log) SERVER pg_proauditlog  
  OPTIONS (filename 'path_to_PGDATA/audit/audit-5.csv', FORMAT 'csv');
CREATE FOREIGN TABLE pg_proaudit_log_6 () INHERITS (pg_proaudit_log) SERVER pg_proauditlog  
  OPTIONS (filename 'path_to_PGDATA/audit/audit-6.csv', FORMAT 'csv');
CREATE FOREIGN TABLE pg_proaudit_log_7 () INHERITS (pg_proaudit_log) SERVER pg_proauditlog  
  OPTIONS (filename 'path_to_PGDATA/audit/audit-7.csv', FORMAT 'csv');
CREATE FOREIGN TABLE pg_proaudit_log_6 () INHERITS (pg_proaudit_log) SERVER pg_proauditlog OPTIONS (filename '/path_to_PGDATA/audit/audit-6.csv', FORMAT 'csv');
CREATE FOREIGN TABLE pg_proaudit_log_7 () INHERITS (pg_proaudit_log) SERVER pg_proauditlog OPTIONS (filename '/path_to_PGDATA/audit/audit-7.csv', FORMAT 'csv');

To set up logging for the required security events, connect to the postgres database and execute the following commands:

```
SELECT pg_proaudit_set_object ('CONNECT', null);
SELECT pg_proaudit_set_object ('DISCONNECT', null);
SELECT pg_proaudit_set_object ('ALL', 'table');
SELECT pg_proaudit_set_role ('ALL', 'postgres'::regrole);
```

Create the app_table table and enable logging for all operations on this table:

```
CREATE TABLE app_table (id int, name text);
SELECT pg_proaudit_set_object ('ALL', 'public.app_table'::regclass);
```

Check that event logging is configured as expected:

```
pinggres=# SELECT * FROM pg_proaudit_settings;
          db_name       | event_type | object_type | object_name    | role_name
-----------------+------------+-------------+----------------+-----------
              postgres | DISCONNECT |             | 0              | 0         
              postgres | CONNECT    |             | 0              | 0         
              postgres | ALL        | TABLE       | 0              | 0         
              postgres | ALL        |             | public.app_table| 0         
              postgres | ALL        |             | 0              | postgres  
(5 rows)
```

Save these configuration settings into the pg_proaudit.conf file, so that they are not lost after the server restart:

```
SELECT pg_proaudit_save();
```

Let's run several queries on the app_table table:

```
INSERT INTO app_table VALUES (1, 'first');
SELECT * FROM app_table;
```

Check the log entries for the app_table table:

```
SELECT to_char(log_time, 'DD.MM.YY HH24:MI:SS') AS when, role_name, session_pid, event_type, query_text
FROM pg_proaudit_log
where object_name = 'public.app_table';
```

```
- [ RECORD 1 ]--------------------------------------------------
  when | 24.11.16 16:31:16
  role_name | postgres
  session_pid | 26513
  event_type | CREATE TABLE
  query_text | CREATE TABLE app_table (id int, name text);
- [ RECORD 2 ]--------------------------------------------------
  when | 24.11.16 16:31:53
  role_name | postgres
  session_pid | 26513
  event_type | INSERT
  query_text | INSERT INTO app_table VALUES (1, 'first');
- [ RECORD 3 ]--------------------------------------------------
  when | 24.11.16 16:31:54
```
We have set up a weekly rotation of log files, with the log file switched once a day. It means that queries to the `pg_proaudit_log` table will return only those security events that have happened in the latest week. Older events will be automatically removed at log file rotation. To define additional access constraints for specific log entries, you can create separate views based on queries to the `pg_proaudit_log` table and grant read rights to such views using built-in Postgres Pro access control methods.

**F.37. pgpro_pwr**

The pgpro_pwr module is designed to discover most resource-intensive activities in your database. (PWR, pronounced like "power", is an abbreviation of Postgres Pro Workload Reporting.) This extension is based on Postgres Pro's Statistics Collector views and the `pgpro_stats` or `pg_stat_statements` extension.

**Note**

Although pgpro_pwr can work with the `pg_stat_statements` extension, it is recommended that you use the `pgpro_stats` extension since it provides statement plans, wait events sampling and load distribution statistics for databases, roles, client hosts and applications.

Below, use of `pgpro_stats` is assumed unless otherwise noted.

If you cannot use `pgpro_stats` for an observed database, but the `pg_stat_kcache` extension is available, `pgpro_pwr` can process `pg_stat_kcache` data, which also provides information about CPU resource usage of statements and filesystem load (`rusage`).

`pgpro_pwr` is based on cumulative statistics sampling. Each sample contains statistic increments for most active objects and queries since the time when the previous sample was taken, or more concisely, since the previous sample. This data is later used to generate reports.

`pgpro_pwr` provides functions to collect samples. Regular sampling allows building a report on the database workload in the past.

`pgpro_pwr` allows you to take explicit samples during batch processing, load testing, etc.

Any time a sample is taken, `pgpro_stats_statements_reset()` (see `pgpro_stats` for the function description) is called to ensure that statement statistics will not be lost when the statements count exceed `pgpro_stats.max` (see Section F.39.7.1). The report will also contain a section informing you of whether the count of captured statements in any sample reaches 90% of `pgpro_stats.max`.

`pgpro_pwr` installed on one Postgres Pro server can also collect statistics from other servers. This feature is useful for gathering workload statistics from hot standbys on the master server. To benefit from it, make sure that all server names and connection strings are specified and that the `pgpro_pwr` server can connect to all databases on all servers.

**F.37.1. pgpro_pwr Architecture**

The extension consists of the following parts:

- **Historical repository** is a storage for sampling data. The repository is a set of extension tables.

**Note**

Among the rest, `pgpro_pwr` tables store query texts, which can contain sensitive information. So, for security reasons, restrict access to the repository as appropriate.
Additional Supplied Modules

- **Sample management engine** comprises functions used to take samples and maintain the repository by removing obsolete sample data.

- **Report engine** comprises functions for generating reports based on data from the historical repository.

- **Administrative functions** allow you to create and manage servers and baselines.

### F.37.2. Prerequisites

The prerequisites assume that pgpro_pwr, which is usually installed in a target cluster, i.e., the cluster that you will mainly track the workload for, the extension can also collect performance data from other clusters.

#### F.37.2.1. For the pgpro_pwr Database

The pgpro_pwr extension depends on PL/pgSQL and the dblink extension.

#### F.37.2.2. For the Target Server

The target server must allow connections to all databases from the server where pgpro_pwr is running. To connect to the target server, provide a connection string where a particular database on this server is specified. This database is of high importance for pgpro_pwr since the functionality of the pgpro_stats or pg_stat_statements extensions will be provided through this database. Note, however, that pgpro_pwr will also connect to all the other databases on this server.

Optionally, for completeness of gathered statistics:

- If statement statistics are needed in reports, pgpro_stats must be installed and configured in the aforementioned database. The following settings may affect the completeness and accuracy of gathered statistics:
  - **pgpro_stats.max**
    
    Low setting of this parameter may cause some statement statistics to be wiped out before the sample is taken. A report will warn you if the value of pgpro_stats.max seems undersized.
  - **pgpro_stats.track**
    
    Avoid changing the default value of 'top' (note that the value of 'all' will affect the accuracy of %Total fields for statements-related sections of a report).
  - Set the parameters of the Postgres Pro's Statistics Collector as follows:
    ```
    track_activities = on
    track_counts = on
    track_io_timing = on
    track_wal_io_timing = on   # Since PostgreSQL 14
    track_functions = all/pl
    ```

### F.37.3. Installation and Setup

#### Note

pgpro_pwr creates a bunch of database objects, so installation in a dedicated schema is recommended.

Although the use of pgpro_pwr with superuser privileges does not have any issues, superuser privileges are not necessary. So you can choose one of the following setup procedures depending on your configuration and security requirements or customize them to meet your needs:
**F.37.3.1. Simple Setup**

Use this setup procedure when pgpro_pwr is to be installed on the target cluster to only track its workload as superuser.

Create a schema for the pgpro_pwr installation and create the extension:

```
CREATE SCHEMA profile;
CREATE EXTENSION pgpro_pwr SCHEMA profile;
```

**F.37.3.2. Complex Setup**

Use this setup procedure when you intend to use pgpro_pwr for tracking workload on one or more servers and need to follow the principle of least privilege.

**F.37.3.2.1. In the Target Server Database**

Create a user for pgpro_pwr on the target server:

```
CREATE USER stat_user PASSWORD 'stat_user_pwd';
```

Make sure this user has permissions to connect to any database in the target cluster (by default, it is true) and that pg_hba.conf permits such a connection from the pgpro_pwr database host. Also, grant stat_user with membership in the pg_read_all_stats role and the EXECUTE privilege on the pgpro_stats_statements_reset() function:

```
GRANT pg_read_all_stats TO stat_user;
GRANT EXECUTE ON FUNCTION pgpro_stats_statements_reset TO stat_user;
```

**F.37.3.2.2. In the pgpro_pwr Database**

Create an unprivileged user:

```
CREATE USER pwr_user;
```

This user will be the owner of the extension schema and will collect samples.

Create a schema for the pgpro_pwr installation:

```
CREATE SCHEMA profile AUTHORIZATION pwr_user;
```

Grant the USAGE privilege on the schema where the dblink extension resides:

```
GRANT USAGE ON SCHEMA public TO pwr_user;
```

Create the extension using pwr_user account:

```
\c - pwr_user
CREATE EXTENSION pgpro_pwr SCHEMA profile;
```

Define the connection parameters of the target server for pgpro_pwr. For example:

```
SELECT profile.create_server('target_server_name','host=192.168.1.100 dbname=postgres port=5432');
```

The connection string provided will be used in the dblink_connect() call while executing the take_sample() function.

**Note**

Connection strings are stored in a pgpro_pwr table in clear-text form. Make sure no other database users can access tables of the pgpro_pwr extension.
F.37.3.3. Setting Extension Parameters

In `postgresql.conf`, you can define the following `pgpro_pwr` parameters:

- **`pgpro_pwr.max` (integer)**
  
  Number of top objects (statements, relations, etc.) to be reported in each sorted report table. This parameter affects the size of a sample.
  
  The default value is 20.

- **`pgpro_pwr.max_sample_age` (integer)**
  
  Retention time of the sample, in days. Samples aged `pgpro_pwr.max_sample_age` days and older are automatically deleted on the next `take_sample()` call.
  
  The default value is 7 days.

- **`pgpro_pwr.track_sample_timings` (boolean)**
  
  Enables collecting detailed timing statistics of `pgpro_pwr`'s own sampling procedures. Set this parameter to diagnose why sampling functions run slowly. Collected timing statistics will be available in the `v_sample_timings` view.
  
  The default value is off.

F.37.4. Managing Servers

Once installed, `pgpro_pwr` creates one enabled local server for the current cluster. If a server is enabled, `pgpro_pwr` includes it in sampling when no server is explicitly specified (see `take_sample()` for details). A server that is not enabled is referred to as disabled.

The default connection string for a local node contains only `dbname` and `port` parameters. The values of these parameters are taken from the connection used to create the extension. You can change the server connection string using the `set_server_connstr()` function when needed.

F.37.4.1. Server Management Functions

Use the following `pgpro_pwr` functions for server management:

```sql
create_server(server name, connstr text, enabled boolean DEFAULT TRUE, max_sample_age integer DEFAULT NULL, description text DEFAULT NULL)
```

Creates a server definition.

Arguments:

- `server` — server name. Must be unique.
- `connstr` — connection string. Must contain all the necessary settings to connect from `pgpro_pwr` server to the target server database.
- `enabled` — set to include the server in sampling by the `take_sample()` function without arguments.
- `max_sample_age` — retention time of the sample. Overrides the global `pgpro_pwr.max_sample_age` setting for this server.
- `description` — server description text, to be included in reports.

Here is an example of how to create a server definition:

```sql
SELECT profile.create_server('omega','host=192.168.1.100 dbname=postgres port=5432');
```

```sql
drop_server(server name)
```

Drops a server and all its samples.
**F.37.5. Managing Samples**

A sample contains the database workload statistics since the previous sample.

**F.37.5.1. Sampling Functions**

The following pgpro_pwr functions relate to sampling:

```plaintext
take_sample()
take_sample(server name [, skip_sizes boolean])
```

Takes samples.

If the parameter is omitted, the function takes a sample on each enabled server. Servers are accessed for sampling sequentially, one by one. The function returns a table with the following columns:

- **server** — server name.
- **result** — result of taking the sample. Can be OK if the sample was taken successfully or contain the error trace text in case of exception.
- **elapsed** — time elapsed while the sample was taken.

If called with the parameter, the function takes a sample on the specified server even if this server is disabled. Use when you need different sampling frequencies on specific servers. Returns 0 on success.

Arguments:

- **server** — server name.
- **skip_sizes** — if omitted or set to null, the size-collection policy applies; if false, relation sizes are collected; if true, the collection of relation sizes is skipped.
take_sample_subset([sets_cnt integer, current_set integer])

Takes a sample on each server in a subset of servers. Use to take samples on servers in parallel if you have many enabled servers. Although PL/pgSQL does not support parallel execution, you can call this function in parallel sessions. This function returns the same type as take_sample(). If both parameters are omitted, the function behaves like the take_sample() function, i.e., it takes a sample on all enabled servers one by one.

Arguments:

- sets_cnt — number of subsets to divide all enabled servers into.
- current_set — number of the subset to collect samples for. Takes values from 0 through sets_cnt - 1. For the specified subset, samples are collected as usual, server by server.

If a reset of statistics since the previous sample was detected, pgpro_pwr treats corresponding absolute values as differentials; however, the accuracy will be affected anyway.

show_samples([server name], [days integer])

Returns a table with information on server samples (local server is assumed if server is omitted) for the last days days (all existing samples are assumed if omitted). This table has the following columns:

- sample — sample identifier.
- sample_time — time when this sample was taken.
- dbstats_reset — NULL or the statistics reset timestamp of the pg_stat_database view if the statistics were reset since the previous sample.
- clustats_reset — NULL or the statistics reset timestamp of the pg_stat_bgwriter view if the statistics were reset since the previous sample.
- archstats_reset — NULL or the statistics reset timestamp of the pg_stat_archiver view if the statistics were reset since the previous sample.

Sampling functions also maintain the server repository by deleting obsolete samples and baselines according to the retention policy.

F.37.5.2. Taking Samples

To take samples for all enabled servers, call the take_sample() function. Usually, one or two samples per hour is sufficient. You can use a cron-like tool to schedule sampling. Here is an example for a 30-minute sampling period:

*/30 * * * *   psql -c 'SELECT profile.take_sample()' &> /dev/null

However, the results of such a call are not checked for errors. In a production environment, function results can be used for monitoring. This function returns OK for all servers with successfully taken samples and shows error text for failed servers:

```
SELECT * FROM take_sample();
server | result
----- | ---------------
ok_node | OK
| 00:00:00.48
fail_node | could not establish connection
| 00:00:00
   | SQL statement "SELECT dblink_connect('server_connection',server_connstr)"
   | PL/pgSQL function take_sample(integer) line 69 at PERFORM
```

2382
F.37.5.3. Sample Retention Policy

You can define sample retention at the following levels:

1. **Global**

   The value of the `pgpro_pwr.max_sample_age` parameter in the `postgresql.conf` file defines a common retention setting, which is effective if none of other related settings are defined.

2. **Server**

   Specifying the `max_sample_age` parameter while creating a server or calling the `set_server_max_sample_age(server, max_sample_age)` function for an existing server defines the retention for the server. A server retention setting overrides `pgpro_pwr.max_sample_age` for a specific server.

3. **Baseline**

   A baseline created overrides all the other retention periods for included samples.

F.37.6. Managing the Collection of Relation Sizes

It may take considerable time to collect sizes of all relations in a database by Postgres Pro relation-size functions. Besides, those functions require `ACCESSEXCLUSIVELOCK` on a relation. However, it may be sufficient for you to collect relation sizes on a daily basis. `pgpro_pwr` allows you to skip collecting relation sizes by defining the `size-collection policy` for servers. The policy defines:

- A daily window when the collection of relation sizes is permitted.
- A minimum gap between two samples with relation sizes collected.

When the size-collection policy is defined, sampling functions collect relation sizes only when the sample is taken in the defined window and the previous sample with sizes is older than the gap. The following function defines this policy:

```
set_server_size_sampling(server name, window_start time with time zone DEFAULT NULL, window_duration interval hour to second DEFAULT NULL, sample_interval interval day to minute DEFAULT NULL)
```

Defines the size-collection policy for a server.

Arguments:

- `server` — server name.
- `window_start` — start time of the size-collection window.
- `window_duration` — duration of the size-collection window.
- `sample_interval` — minimum time gap between two samples with relation sizes collected.

**Note**

When you build a report between samples either of which lacks relation-size data, relation-growth sections will be based on `pg_class.relpages` data. However, you can expand the report interval
bounds to the nearest samples with relation sizes collected using the \texttt{with\_growth} parameter of report generation functions; this makes the growth data more accurate.

Relation sizes are needed to calculate sequentially scanned volume for tables and explicit vacuum load for indexes.

Example:

```sql
SELECT set_server_size_sampling('local','23:00+03',interval '2 hour',interval '8 hour');
```

The \texttt{show\_servers\_size\_sampling} function shows size collection policies for all servers:

```sql
postgres=# SELECT * FROM show_servers_size_sampling();
server_name | window_start | window_end  | window_duration | sample_interval |
limited_collection
-------------+--------------+-------------+-----------------+-----------------
+-------------------+
local       | 23:00:00+03  | 01:00:00+03 | 02:00:00        | 08:00:00        | t
```

### F.37.7. Managing Baselines

A \textit{baseline} is a named sequence of samples that has its own retention setting. A baseline can be used as a sample interval in report generation functions. An undefined baseline retention means infinite retention. Use baselines to save information about the database workload for a certain time interval.

#### F.37.7.1. Baseline Management Functions

Use the following \texttt{pgpro\_pwr} functions for baseline management:

- \texttt{create\_baseline([server name,] baseline varchar(25), start_id integer, end_id integer [, days integer])}
- \texttt{create\_baseline([server name,] baseline varchar(25), time\_range tstzrange [, days integer])}

Creates a baseline.

Arguments:

- \textit{server} — server name. \texttt{local} server is assumed if omitted.
- \textit{baseline} — baseline name. Must be unique for a server.
- \textit{start\_id} — identifier of the first sample in the baseline.
- \textit{end\_id} — identifier of the last sample in the baseline.
- \textit{time\_range} — time interval for the baseline. The baseline will include all samples for the minimal interval that covers \texttt{time\_range}.
- \textit{days} — baseline retention time, defined in integer days since \texttt{now()}. Omit or set to null for infinite retention.

- \texttt{drop\_baseline([server name,] baseline varchar(25))}

Drops a baseline. For the meaning and usage details of function arguments, see \texttt{create\_baseline}. Dropping a baseline does not mean dropping all its samples immediately. The baseline retention just no longer applies to them.

- \texttt{keep\_baseline([server name,] baseline varchar(25) [, days integer])}

Changes the retention of a baseline. For the meaning and usage details of function arguments, see \texttt{create\_baseline}. Omit the \texttt{baseline} parameter or pass null to it to change the retention of all existing baselines.
show_baselines([server name])

Displays existing baselines. Call show_baselines to get information about the baselines, such as names, sampling intervals and retention periods. local sever is assumed if the server parameter is omitted.

F.37.8. Data Export and Import

Collected samples can be exported from one instance of the pgpro_pwr extension and then loaded into another one. This feature helps you to move server data from one instance to another or to send collected data to your support team.

F.37.8.1. Data Export

The export_data function exports data to a regular table. You can use any method available to export this table from your database. For example, you can use the \copy meta-command of psql to obtain a single csv file:

```sql
postgres=# \copy (select * from export_data()) to 'export.csv'
```

F.37.8.2. Data Import

Since data can only be imported from a local table, first, load the data you exported. Using the \copy meta-command again:

```sql
postgres=# CREATE TABLE import (section_id bigint, row_data json);
CREATE TABLE
postgres=# \copy import from 'export.csv'
COPY 6437
```

Now you can import the data by providing the import table to the import_data function:

```sql
postgres=# SELECT * FROM import_data('import');
```

After successful import, you can drop the import table.

Note

If server data is imported for the first time, your local pgpro_pwr servers with matching names will cause a conflict during import. To avoid this, you can temporarily rename such servers. However, during import of new data for already imported servers, they are matched by system identifiers, so feel free to rename imported servers. Also keep in mind that pgpro_pwr sets servers being imported to the disabled state for take_sample() to bypass them.

F.37.8.3. Export and Import Functions

Use these functions to export or import data:

```sql
export_data([server name, [min_sample_id integer,] [max_sample_id integer]], [, obfuscate_queries boolean]])
```

Exports collected data.

Arguments:

- server — server name. All configured servers are assumed if omitted.
- min_sample_id, max_sample_id — sample identifiers to bound the export (inclusive). If min_sample_id is omitted or set to null, all samples until max_sample_id sample are exported; if max_sample_id is omitted or set to null, all samples since min_sample_id sample are exported.
- obfuscate_queries — if true, query texts are exported as MD5 hash.

```sql
import_data(data regclass)
```

Imports previously exported data. Returns the number of actually loaded rows in pgpro_pwr tables.
pgpro_pwr reports are generated in HTML format by reporting functions. The following types of reports are available:

- **Regular reports** provide statistics on the workload for an interval.
- **Differential reports** provide statistics on the same objects for two intervals. Corresponding values are located next to each other, which makes it easy to compare the workloads.

Reporting functions take sample identifiers, baselines or time ranges to determine the intervals. For time ranges, these are the minimal intervals that cover the ranges.

### F.37.9.1. Regular Reports

Use this function to generate regular reports:

```sql
get_report([server name,] start_id integer, end_id integer [,, description text [, with_growth boolean]])
generate_report([server name,] time_range tstzrange [,, description text [, with_growth boolean]])
generate_report([server name,] baseline varchar(25) [,, description text [, with_growth boolean]])
```

Generates a regular report.

**Arguments:**

- **server** — server name. `local server` is assumed if omitted.
- **start_id** — identifier of the interval starting sample.
- **end_id** — identifier of the interval ending sample.
- **baseline** — baseline name.
- **time_range** — time range.
- **description** — short text to be included in the report as its description.
- **with_growth** — flag requesting interval expansion to the nearest bounds with data on relation growth available. The default value is `false`.

### F.37.9.2. Differential Reports

Use this function to generate differential reports:

```sql
get_diffreport([server name,] start1_id integer, end1_id integer, start2_id integer, end2_id integer [,, description text [, with_growth boolean]])
generate_diffreport([server name,] time_range1 tstzrange, time_range2 tstzrange [,, description text [, with_growth boolean]])
generate_diffreport([server name,] baseline1 varchar(25), baseline2 varchar(25) [,, description text [, with_growth boolean]])
generate_diffreport([server name,] baseline1 varchar(25), time_range2 tstzrange [,, description text [, with_growth boolean]])
generate_diffreport([server name,] baseline1 varchar(25), baseline2 varchar(25) [,, description text [, with_growth boolean]])
generate_diffreport([server name,] time_range1 tstzrange, baseline2 varchar(25) [,, description text [, with_growth boolean]])
generate_diffreport([server name,] start1_id integer, end1_id integer, baseline2 varchar(25) [,, description text [, with_growth boolean]])
generate_diffreport([server name,] baseline1 varchar(25), start2_id integer, end2_id integer [,, description text [, with_growth boolean]])
```

Generates a differential report for two intervals. The combinations of arguments provide possible ways to specify the two intervals.
Arguments:

- `server` — server name. `local` server is assumed if omitted.
- `start1_id, end1_id` — identifiers of the starting and ending samples for the first interval.
- `start2_id, end2_id` — identifiers of the starting and ending samples for the second interval.
- `baseline1` — baseline name for the first interval.
- `baseline2` — baseline name for the second interval.
- `time_range1` — time range for the first interval.
- `time_range2` — time range for the second interval.
- `description` — short text to be included in the report as its description.
- `with_growth` — flag requesting interval expansion to the nearest bounds with data on relation growth available. The default value is `false`.

F.37.9.3. Report Generation Example

Generate a report for the `local` server and interval defined by samples:

```
psql -Aqtc "SELECT profile.get_report(480,482)" -o report_480_482.html
```

For any other server, provide its name:

```
psql -Aqtc "SELECT profile.get_report('omega',12,14)" -o report_omega_12_14.html
```

Generate a report using time ranges:

```
```

Generate a relative time-range report:

```
psql -Aqtc "SELECT profile.get_report(tstzrange(now() - interval '1 day',now()))" -o report_last_day.html
```

F.37.10. pgpro_pwr Report Sections

Each `pgpro_pwr` report is divided into sections, described below. The number of top objects reported in each sorted report table is specified by the `pgpro_pwr.max` parameter.

F.37.10.1. Server statistics

Tables in this section of a `pgpro_pwr` report are described below.

The report table “Database statistics” provides per-database statistics for the report interval. The statistics are based on the `pg_stat_database` view. Table F.21 lists columns of this report table.

Table F.21. Database statistics

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
<th>Field/Calculation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Database name</td>
<td>datname</td>
</tr>
<tr>
<td>Commits</td>
<td>Number of committed transactions</td>
<td>xact_commit</td>
</tr>
<tr>
<td>Rollbacks</td>
<td>Number of rolled back transactions</td>
<td>xact_rollback</td>
</tr>
<tr>
<td>Deadlocks</td>
<td>Number of deadlocks detected</td>
<td>deadlocks</td>
</tr>
</tbody>
</table>
### Additional Supplied Modules

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
<th>Field/Calculation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hit%</td>
<td>Buffer cache hit ratio, i.e., percentage of pages fetched from buffers in all pages fetched</td>
<td></td>
</tr>
<tr>
<td>Read</td>
<td>Number of disk blocks read in this database</td>
<td>blks_read</td>
</tr>
<tr>
<td>Hit</td>
<td>Number of times disk blocks were found already in the buffer cache</td>
<td>blks_hit</td>
</tr>
<tr>
<td>Ret</td>
<td>Number of returned tuples</td>
<td>tup_returned</td>
</tr>
<tr>
<td>Fet</td>
<td>Number of fetched tuples</td>
<td>tup_fetched</td>
</tr>
<tr>
<td>Ins</td>
<td>Number of inserted tuples</td>
<td>tup_inserted</td>
</tr>
<tr>
<td>Upd</td>
<td>Number of updated tuples</td>
<td>tup_updated</td>
</tr>
<tr>
<td>Del</td>
<td>Number of deleted tuples</td>
<td>tup_deleted</td>
</tr>
<tr>
<td>Temp Size</td>
<td>Total amount of data written to temporary files by queries in this database</td>
<td>temp_bytes</td>
</tr>
<tr>
<td>Temp Files</td>
<td>Number of temporary files created by queries in this database</td>
<td>temp_files</td>
</tr>
<tr>
<td>Size</td>
<td>Database size at the time of the last sample in the report interval</td>
<td>pg_database_size()</td>
</tr>
<tr>
<td>Growth</td>
<td>Database growth during the report interval</td>
<td>pg_database_size()</td>
</tr>
</tbody>
</table>

Table “Session statistics by database” is available in the report for Postgres Pro databases starting with version 14. This table is based on the `pg_stat_database` view of the Statistics Collector. Table F.22 lists columns of this report table. Times are provided in seconds.

### Table F.22. Session statistics by database

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
<th>Field/Calculation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Database name</td>
<td></td>
</tr>
<tr>
<td>Timing Total</td>
<td>Time spent by database sessions in this database during the report interval (note that statistics are only updated when the state of a session changes, so if sessions have been idle for a long time, this idle time won’t be included)</td>
<td>session_time</td>
</tr>
<tr>
<td>Timing Active</td>
<td>Time spent executing SQL statements in this database during the report interval (this corresponds to the states active and fastpath function call in <code>pg_stat_activity</code>)</td>
<td>active_time</td>
</tr>
<tr>
<td>Timing Idle(T)</td>
<td>Time spent idling while in a transaction in this database during the report interval (this corresponds to the states idle</td>
<td>idle_in_transaction_time</td>
</tr>
</tbody>
</table>

2388
<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
<th>Field/Calculation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sessions Established</td>
<td>Total number of sessions established to this database during the report interval</td>
<td>sessions</td>
</tr>
<tr>
<td>Sessions Abandoned</td>
<td>Number of database sessions to this database that were terminated because connection to the client was lost during the report interval</td>
<td>sessions_abandoned</td>
</tr>
<tr>
<td>Sessions Fatal</td>
<td>Number of database sessions to this database that were terminated by fatal errors during the report interval</td>
<td>sessions_fatal</td>
</tr>
<tr>
<td>Sessions Killed</td>
<td>Number of database sessions to this database that were terminated by operator intervention during the report interval</td>
<td>sessions_killed</td>
</tr>
</tbody>
</table>

If the `pgpro_stats` extension was available during the report interval, the "Statement statistics by database" table of the report provides per-database aggregated total statistics for the `pgpro_stats_statements` view data. Table F.23 lists columns of this report table. Times are provided in seconds.

### Table F.23. Statement statistics by database

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
<th>Field/Calculation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Database name</td>
<td>calls</td>
</tr>
<tr>
<td>Calls</td>
<td>Number of times all statements in the database were executed</td>
<td>sum of total_plan_time</td>
</tr>
<tr>
<td>Plan Time</td>
<td>Time spent planning all statements in the database</td>
<td>sum of total_exec_time</td>
</tr>
<tr>
<td>Exec Time</td>
<td>Time spent executing all statements in the database</td>
<td>sum of blk_read_time</td>
</tr>
<tr>
<td>Read Time</td>
<td>Time spent reading blocks by all statements in the database</td>
<td>sum of blk_write_time</td>
</tr>
<tr>
<td>Write Time</td>
<td>Time spent writing blocks by all statements in the database</td>
<td></td>
</tr>
<tr>
<td>Trg Time</td>
<td>Time spent executing trigger functions by all statements in the database</td>
<td></td>
</tr>
<tr>
<td>Shared Fetched</td>
<td>Total number of shared blocks fetched by all statements in the database</td>
<td>sum of (shared_blks_read + shared_blks_hit)</td>
</tr>
<tr>
<td>Local Fetched</td>
<td>Total number of local blocks fetched by all statements in the database</td>
<td>sum of (local_blks_read + local_blks_hit)</td>
</tr>
<tr>
<td>Shared Dirtied</td>
<td>Total number of shared blocks dirtied by all statements in the database</td>
<td>sum of shared_blks_dirtied</td>
</tr>
</tbody>
</table>
### Additional Supplied Modules

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
<th>Field/Calculation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Local Dirtied</td>
<td>Total number of local blocks dirtied by all statements in the database</td>
<td>Sum of local_blks_dirtied</td>
</tr>
<tr>
<td>Read Temp</td>
<td>Total number of temp blocks read by all statements in the database</td>
<td>Sum of temp_blks_read</td>
</tr>
<tr>
<td>Write Temp</td>
<td>Total number of temp blocks written by all statements in the database</td>
<td>Sum of temp_blks_written</td>
</tr>
<tr>
<td>Read Local</td>
<td>Total number of local blocks read by all statements in the database</td>
<td>Sum of local_blks_read</td>
</tr>
<tr>
<td>Write Local</td>
<td>Total number of local blocks written by all statements in the database</td>
<td>Sum of local_blks_written</td>
</tr>
<tr>
<td>Statements</td>
<td>Total number of captured statements</td>
<td></td>
</tr>
<tr>
<td>WAL Size</td>
<td>Total amount of WAL generated by all statements in the database</td>
<td>Sum of wal_bytes</td>
</tr>
</tbody>
</table>

The report table “Cluster statistics” provides data from the `pg_statbgwriter` view. Table F.24 lists rows of this report table. Times are provided in seconds.

### Table F.24. Cluster statistics

<table>
<thead>
<tr>
<th>Row</th>
<th>Description</th>
<th>Field/Calculation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scheduled checkpoints</td>
<td>Number of scheduled checkpoints that have been performed</td>
<td>checkpoints_timed</td>
</tr>
<tr>
<td>Requested checkpoints</td>
<td>Number of requested checkpoints that have been performed</td>
<td>checkpoints_req</td>
</tr>
<tr>
<td>Checkpoint write time (s)</td>
<td>Total amount of time that has been spent in the portion of checkpoint processing where files are written to disk</td>
<td>checkpoint_write_time</td>
</tr>
<tr>
<td>Checkpoint sync time (s)</td>
<td>Total amount of time that has been spent in the portion of checkpoint processing where files are synchronized to disk</td>
<td>checkpoint_sync_time</td>
</tr>
<tr>
<td>Checkpoint buffers written</td>
<td>Number of buffers written during checkpoints</td>
<td>buffers_checkpoint</td>
</tr>
<tr>
<td>Background buffers written</td>
<td>Number of buffers written by the background writer</td>
<td>buffers_clean</td>
</tr>
<tr>
<td>Backend buffers written</td>
<td>Number of buffers written directly by a backend</td>
<td>buffers_backend</td>
</tr>
<tr>
<td>Backend fsync count</td>
<td>Number of times a backend had to execute its own fsync call (normally the background writer handles those even when the backend does its own write)</td>
<td>buffers_backend_fsync</td>
</tr>
<tr>
<td>Bgwriter interrupts (too many buffers)</td>
<td>Number of times the background writer stopped a cleaning scan</td>
<td>maxwritten_clean</td>
</tr>
</tbody>
</table>
Table “WAL statistics” is available in the report for Postgres Pro databases starting with version 14. This table is based on the pg_stat_wal view of the Statistics Collector. Table F.25 lists columns of this report table. Times are provided in seconds.

Table F.25. WAL statistics

<table>
<thead>
<tr>
<th>Row</th>
<th>Description</th>
<th>Field/Calculation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of buffers allocated</td>
<td>Total number of buffers allocated</td>
<td>buffers_alloc</td>
</tr>
<tr>
<td>WAL generated</td>
<td>Total amount of WAL generated</td>
<td>pg_current_wal_lsn() value increment</td>
</tr>
<tr>
<td>WAL segments archived</td>
<td>Total number of archived WAL segments</td>
<td>Based on pg_stat_archiver.archived_count</td>
</tr>
<tr>
<td>WAL segments archive failed</td>
<td>Total number of WAL segment archiver failures</td>
<td>Based on pg_stat_archiver.failed_count</td>
</tr>
</tbody>
</table>

Additional Supplied Modules
<table>
<thead>
<tr>
<th>Row</th>
<th>Description</th>
<th>Field/Calculation</th>
</tr>
</thead>
<tbody>
<tr>
<td>WAL syncs per second</td>
<td>Average number of times WAL files were synced to disk via issue_xlog_fsync</td>
<td>wal_sync / report_duration</td>
</tr>
<tr>
<td></td>
<td>request per second during the report interval</td>
<td></td>
</tr>
<tr>
<td>WAL write time</td>
<td>Total amount of time spent writing WAL buffers to disk via XLogWrite request</td>
<td>wal_write_time</td>
</tr>
<tr>
<td></td>
<td>during the report interval (if track_wal_io_timing is enabled, otherwise zero; for more details, see Section 18.9). This includes the sync time when wal_sync_method is either open_datsasync or open_sync.</td>
<td></td>
</tr>
<tr>
<td>WAL write duty</td>
<td>WAL write time as the percentage of the report interval duration</td>
<td>wal_write_time * 100 / report_duration</td>
</tr>
<tr>
<td>WAL sync time</td>
<td>Total amount of time spent syncing WAL files to disk via issue_xlog_fsync</td>
<td>wal_sync_time</td>
</tr>
<tr>
<td></td>
<td>request during the report interval (if track_wal_io_timing is enabled, fsync is on, and wal_sync_method is either fdatasync, fsync or fsync_writethrough, otherwise zero).</td>
<td></td>
</tr>
<tr>
<td>WAL sync duty</td>
<td>WAL sync time as the percentage of the report interval duration</td>
<td>wal_sync_time * 100 / report_duration</td>
</tr>
</tbody>
</table>

The report table “Tablespace statistics” provides information on the sizes and growth of tablespaces. Table F.26 lists columns of this report table.

Table F.26. Tablespace statistics

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
<th>Field/Calculation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tablespace</td>
<td>Tablespace name</td>
<td>pg_tablespace .spcname</td>
</tr>
<tr>
<td>Path</td>
<td>Tablespace path</td>
<td>pg_tablespace_location()</td>
</tr>
<tr>
<td>Size</td>
<td>Tablespace size at the time of the</td>
<td>pg_tablespace_size()</td>
</tr>
<tr>
<td></td>
<td>last sample in the report interval</td>
<td></td>
</tr>
<tr>
<td>Growth</td>
<td>Tablespace growth during the report</td>
<td></td>
</tr>
<tr>
<td></td>
<td>interval</td>
<td></td>
</tr>
</tbody>
</table>

If the pgpro_stats extension was available during the report interval, the report table “Wait statistics by database” shows the total wait time by wait event type and database. Table F.27 lists columns of this report table.

Table F.27. Wait statistics by database

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Database name</td>
</tr>
</tbody>
</table>
### Additional Supplied Modules

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Wait event type</td>
<td>Type of event for which the backends were waiting. Asterisk means aggregation of all wait event types in the database.</td>
</tr>
<tr>
<td>Waited (s)</td>
<td>Time spent waiting in events of Wait event type, in seconds</td>
</tr>
<tr>
<td>%Total</td>
<td>Percentage of wait time spent in the database events of Wait event type in all wait time for the cluster</td>
</tr>
</tbody>
</table>

If the pgpro_stats extension was available during the report interval, the report table “Top wait events” shows top wait events in the cluster by wait time. Table F.28 lists columns of this report table.

#### Table F.28. Top wait events

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Database name</td>
</tr>
<tr>
<td>Wait event type</td>
<td>The type of event for which the backends were waiting</td>
</tr>
<tr>
<td>Wait event</td>
<td>Wait event name for which the backends were waiting</td>
</tr>
<tr>
<td>Waited</td>
<td>Total wait time spent in Wait event of the database, in seconds</td>
</tr>
<tr>
<td>%Total</td>
<td>Percentage of wait time spent in Wait event of the database in all wait time in the cluster</td>
</tr>
</tbody>
</table>

### F.37.10.2. Load distribution

This section of a pgpro_pwr report is based on the pgpro_stats_totals view of the pgpro_stats extension if it was available during the report interval. Each table in this section provides data for the report interval on load distribution for a certain kind of objects for which aggregated statistics are collected, such as databases, applications, hosts, or users. Each table contains one row for each resource (for example, total time or shared blocks written), where load distribution is shown in graphics, as a stacked bar chart for top objects by load of this resource. If the bar chart area that corresponds to an object is too narrow to include captions, point that area to get a hint with the caption, value and percentage. The report tables “Load distribution among heavily loaded databases”, “Load distribution among heavily loaded applications”, “Load distribution among heavily loaded hosts” and “Load distribution among heavily loaded users” show load distribution for respective objects. Table F.29 lists rows of these report tables.

#### Table F.29. Load distribution

<table>
<thead>
<tr>
<th>Row</th>
<th>Description</th>
<th>Calculation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Total time (sec.)</td>
<td>Total time spent in the planning and execution of statements</td>
<td>total_plan_time + total_exec_time</td>
</tr>
<tr>
<td>Executed count</td>
<td>Number of queries executed</td>
<td>queries_executed</td>
</tr>
<tr>
<td>I/O time (sec.)</td>
<td>Total time the statements spent reading or writing blocks ( if track_io_timing is enabled, otherwise zero)</td>
<td>blk_read_time + blk_write_time</td>
</tr>
<tr>
<td>Blocks fetched</td>
<td>Total number of shared block cache hits and shared blocks read by the statements</td>
<td>shared_blks_hit + shared_blks_read</td>
</tr>
</tbody>
</table>
**Additional Supplied Modules**

<table>
<thead>
<tr>
<th>Row</th>
<th>Description</th>
<th>Calculation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Shared blocks read</td>
<td>Total number of shared blocks read by the</td>
<td>shared_blks_read</td>
</tr>
<tr>
<td></td>
<td>statements</td>
<td></td>
</tr>
<tr>
<td>Shared blocks dirtied</td>
<td>Total number of shared blocks dirtied by the</td>
<td>shared_blks_dirtied</td>

**F.37.10.3. SQL query statistics**

This section of a pgpro_pwr report provides data for the report interval on top statements by several important statistics. The data is mainly captured from views of the one of pgpro_stats and pg_stat_statements extensions that was available during the report interval, with the precedence of pgpro_stats. Tables of this section of the report are described below.

The report table “Top SQL by elapsed time” shows top statements by the sum of total_plan_time and total_exec_time fields of the pgpro_stats_statements or pg_stat_statements view. Table F.30 lists columns of this report table. Times are provided in seconds.

**Table F.30. Top SQL by elapsed time**

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>

<tbody>
<tr>
<td>Query ID</td>
<td>Query identifier, as a hash of database ID, user ID and query text. Hex representation of queryid is in square brackets.</td>
<td></td>
</tr>
</tbody>
</table>
### Column Description Field/Calculation

| **Plan ID** | Internal hash code, computed from the tree of the statement plan | planid |
| **Database** | Database name for the statement | Derived from dbid |
| **Executions** | Number of executions of the statement plan | calls |
| **%Total** | Percentage of calls of this statement plan in the total calls of all statements in the cluster | |
| **Rows** | Number of rows retrieved or affected by execution of the statement plan | rows |
| **Mean (ms)** | Mean time spent executing the statement plan, in milliseconds | mean_exec_time |
| **Min (ms)** | Minimum time spent executing the statement plan, in milliseconds | min_exec_time |
| **Max (ms)** | Maximum time spent executing the statement plan, in milliseconds | max_exec_time |
| **StdErr (ms)** | Population standard deviation of time spent executing the statement plan, in milliseconds | stddev_time |
| **Elapsed(s)** | Total time spent executing the statement plan, in seconds | total_exec_time |

The report table "Top SQL by I/O wait time" shows top statements by read and write time, i.e., sum of values of `blk_read_time` and `blk_write_time` fields of the `pgpro_stats_statements` or `pg_stat_statements` view. Table F.34 lists columns of this report table. Times are provided in seconds.

**Table F.34. Top SQL by I/O wait time**

<td>Percentage of <code>plan_writes + exec_writes</code> in the total number of bytes written by the filesystem layer for all statements</td>
<td></td>
</tr>
</tbody>
</table>

#### F.37.10.4. SQL query wait statistics

If the `pgpro_stats` extension was available during the report interval, this section of the report will contain a table that is split into sections, each showing top statements by overall wait time or by wait time for a certain wait event type. Table sections related to specific wait events follow in the descending order of the total wait time in wait events of this type. Table F.43 lists columns of this report table. Times are provided in seconds.

**Table F.43. SQL query wait statistics**

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
<th>Field/Calculation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Query ID</td>
<td>Query identifier, as a hash of database ID, user ID and query text. Hex representation of <code>queryid</code> in square brackets.</td>
<td></td>
</tr>
<tr>
<td>Plan ID</td>
<td>Hash of the statement plan</td>
<td>planid</td>
</tr>
<tr>
<td>Database</td>
<td>Database name for the statement</td>
<td>Derived from dbid</td>
</tr>
<tr>
<td>Waited</td>
<td>Total wait time for all wait events of this statement plan</td>
<td></td>
</tr>
<tr>
<td>%Total</td>
<td>Percentage of the total wait time of this statement plan in all the wait time in the cluster</td>
<td></td>
</tr>
<tr>
<td>Details</td>
<td>Waits of this statement plan by wait types</td>
<td></td>
</tr>
</tbody>
</table>

#### F.37.10.5. Complete list of SQL texts

The "Complete list of SQL texts" section of the report contains a table that provides query and plan texts for all statements mentioned in the report. Use an appropriate Query ID/Plan ID link in any statistics table to see the corresponding query/plan text. Table F.44 lists columns of this report table.

**Table F.44. Complete list of SQL texts**

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
<td>Query or plan identifier</td>
</tr>
<tr>
<td>Query/Plan Text</td>
<td>Text of the query or statement plan</td>
</tr>
</tbody>
</table>

#### F.37.10.6. Schema object statistics

Tables in this section of the report show top database objects by statistics from the Postgres Pro's Statistics Collector views.

The report table “Top tables by estimated sequentially scanned volume” shows top tables by estimated volume read by sequential scans. This can help you find database tables that possibly lack some index. When there are no relation sizes collected with `pg_relation_size()`, relation-size estimates are based on the `pg_class.relpages` field. Since such values are less accurate, they are shown in square brackets. The data is based on the `pg_stat_all_tables` view. Table F.45 lists columns of this report table.
### Additional Supplied Modules

#### Table F.45. Top tables by estimated sequentially scanned volume

<table>
<thead>
<tr>
<th>Column</th>

</table>

In the report table “Top tables by blocks fetched”, blocks fetched include blocks being processed from disk (read) and from shared buffers (hit). This report table shows top database tables by the sum of blocks fetched for the table’s heap, indexes, TOAST table (if any) and TOAST table index (if any). This can help you focus on tables with excessive processing of blocks. The data is based on the `pg_statio_all_tables` view. **Table F.46** lists columns of this report table.

#### Table F.46. Top tables by blocks fetched

<table>

</tbody>
</table>
The report table “Top tables by blocks read” shows top database tables by the number of blocks read for the table’s heap, indexes, TOAST table (if any) and TOAST table index (if any). This can help you focus on tables with excessive block readings. The data is based on the `pg_statio_all_tables` view. Table F.47 lists columns of this report table.

</tbody>
</table>
The report table “Top growing tables” shows top tables by growth. The data is based on the `pg_stat_all_tables` view. When there are no relation sizes collected with `pg_relation_size()`, relation-size estimates are based on the `pg_class.relpages` field. Since such values are less accurate, they are shown in square brackets. Table F.50 lists columns of this report table.

**Table F.50. Top growing tables**

</tbody>
</table>

**F.37.10.7. User function statistics**

Tables in this section of the report show top functions in the cluster by statistics from the `pg_stat_user_functions` view. Times in the tables are provided in seconds.

The report table “Top functions by total time” shows top functions by the total time elapsed. The report table “Top functions by executions” shows top functions by the number of executions. The report table “Top trigger functions by total time” shows top trigger functions by the total time elapsed. Table F.55 lists columns of these report tables.

**Table F.55. User function statistics**

<table>
<thead>
<tr>

<td>Mean time of a single function execution</td>
<td>total_time / calls</td>
</tr>
<tr>
<td>Mean self Time (s)</td>
<td>Mean self time of a single function execution</td>
<td>self_time / calls</td>
</tr>
</tbody>
</table>

**F.37.10.8. Vacuum-related statistics**

The report table “Top tables by vacuum operations” shows top tables by the number of vacuum operations performed (`vacuum_count + autovacuum_count`). The data is based on the `pg_stat_all_tables` view. Table F.56 lists columns of this report table.
Additional Supplied Modules

Table F.56. Top tables by vacuum operations

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
<th>Field/Calculation</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>Upd(HOT)</td>
<td>Number of rows HOT updated</td>
<td>n_tup_hot_upd</td>
</tr>
</tbody>
</table>

The report table “Top indexes by estimated vacuum load” shows top indexes by estimated implicit vacuum load. This load is calculated as the number of vacuum operations performed on the underlying table multiplied by the index size. The data is based on the pg_stat_all_indexes view. When there are no relation sizes collected with pg_relation_size(), relation-size estimates are based on the pg_class.relpages field. Since such values are less accurate, they are shown in square brackets. Table F.58 lists columns of this report table.
Table F.58. Top indexes by estimated vacuum load

<table>
<thead>

</tr>
</tbody>
</table>

The report table “Top tables by dead tuples ratio” shows top tables larger than 5 MB by the ratio of dead tuples. Statistics are valid for the last sample in the report interval. The data is based on the pg_stat_all_tables view. When there are no relation sizes collected with pg_relation_size(), relation-size estimates are based on the pg_class.relpages field. Since such values are less accurate, they are shown in square brackets. Table F.59 lists columns of this report table.

Table F.59. Top tables by dead tuples ratio

### F.37.12. Important Notes

When using the pgpro_pwr extension, be aware of the following:

- Postgres Pro collects execution statistics after the execution is complete. If a single execution of a statement lasts for several samples, it will only affect statistics of the last sample (in which the execution completed). Besides, statistics on statements that are still running are unavailable. Maintenance processes, such as vacuum and checkpoint, will update the statistics only on completion.
- Resetting any Postgres Pro statistics may affect the accuracy of the next sample.
- Exclusive locks on relations conflict with calculation of the relation size. If the \( \text{take\_sample()} \) function is unable to acquire a lock for a short period of time (3 seconds), it will fail and no sample will be generated.

### F.38. pg_prewarm

The pg_prewarm module provides a convenient way to load relation data into either the operating system buffer cache or the Postgres Pro buffer cache. Prewarming can be performed manually using the pg_prewarm function, or can be performed automatically by including pg_prewarm in shared preload libraries. In the latter case, the system will run a background worker which periodically records the contents of shared buffers in a file called autoprewarm.blocks and will, using 2 background workers, reload those same blocks after a restart.

#### F.38.1. Functions

```sql
pg_prewarm(regclass, mode text default 'buffer', fork text default 'main',
            first_block int8 default null,
            last_block int8 default null) RETURNS int8
```

The first argument is the relation to be prewarmed. The second argument is the prewarming method to be used, as further discussed below; the third is the relation fork to be prewarmed, usually main. The fourth argument is the first block number to prewarm (NULL is accepted as a synonym for zero). The fifth argument is the last block number to prewarm (NULL means prewarm through the last block in the relation). The return value is the number of blocks prewarmed.

There are three available prewarming methods. \( \text{prefetch} \) issues asynchronous prefetch requests to the operating system, if this is supported, or throws an error otherwise. \( \text{read} \) reads the requested range of blocks; unlike \( \text{prefetch} \), this is synchronous and supported on all platforms and builds, but may be slower. \( \text{buffer} \) reads the requested range of blocks into the database buffer cache.

Note that with any of these methods, attempting to prewarm more blocks than can be cached — by the OS when using \( \text{prefetch} \) or \( \text{read} \), or by Postgres Pro when using \( \text{buffer} \) — will likely result in lower-numbered blocks being evicted as higher numbered blocks are read in. Prewarmed data also enjoys no special protection from cache evictions, so it is possible that other system activity may evict the newly prewarmed blocks shortly after they are read; conversely, prewarming may also evict other data from cache. For these reasons, prewarming is typically most useful at startup, when caches are largely empty.

```sql
autoprewarm_start_worker() RETURNS void
autoprewarm_dump_now() RETURNS int8
```

Launch the main autoprewarm worker. This will normally happen automatically, but is useful if automatic prewarm was not configured at server startup time and you wish to start up the worker at a later time.
Additional Supplied Modules

Update autoprewarm.blocks immediately. This may be useful if the autoprewarm worker is not running but you anticipate running it after the next restart. The return value is the number of records written to autoprewarm.blocks.

F.38.2. Configuration Parameters

**pg_prewarm.autoprewarm (boolean)**
Controls whether the server should run the autoprewarm worker. This is on by default. This parameter can only be set at server start.

**pg_prewarm.autoprewarm_interval (int)**
This is the interval between updates to autoprewarm.blocks. The default is 300 seconds. If set to 0, the file will not be dumped at regular intervals, but only when the server is shut down.

F.38.3. Author

Robert Haas <rhaas@postgresql.org>

F.39. pgpro_stats

The pgpro_stats extension provides a means for tracking planning and execution statistics of all SQL statements executed by a server. It is based on the pg_stat_statements module and provides the following additional functionality:

- Storing query plans in addition to query statements.
- Configuring sample rate for statistics collection to reduce overhead.
- Calculating wait event statistics for executed queries.
- Calculating resource usage statistics of statement planning and execution.
- Calculating cache invalidation statistics.

F.39.1. Limitations

- pgpro_stats can sometimes fail to match identical parameters in the query statement and the corresponding query plan.
- Some SPI queries are not included into statistics.
- pgpro_stats may not work correctly with third-party extensions that use parser, planner, or executor hooks to modify parse and plan trees and execution of the queries. In order to dump the final versions of the queries and plans, pgpro_stats should be the last on the list of shared_preload_libraries, but some existing extensions, such as pg_pathman, will not work at all unless they are the last on this list.
- pgpro_stats may not work correctly with third-party extensions that produce CustomScan and ForeignScan nodes.

F.39.2. Installation and Setup

The pgpro_stats extension is included into Postgres Pro Standard, but has to be installed separately. Once you have pgpro_stats installed, complete the following steps to enable pgpro_stats:

1. Add pgpro_stats to the shared_preload_libraries parameter in the postgresql.conf file:

   ```
   shared_preload_libraries = 'pgpro_stats'
   ```

2. Restart the Postgres Pro Standard instance for the changes to take effect.

   Once the server is reloaded, pgpro_stats starts tracking statistics across all databases of the cluster. If required, you can change the scope of statistics collection or disable it altogether using pgpro_stats configuration parameters.

3. To access the collected statistics, you have to create pgpro_stats extension:
CREATE EXTENSION pgpro_stats;

F.39.3. Usage

- Collecting Statistics on Query Statements and Plans
- Monitoring Custom Metrics

F.39.3.1. Collecting Statistics on Query Statements and Plans

Once installed, the `pgpro_stats` extension starts collecting statistics on the executed statements. The collected data is similar to the one provided by `pg_stat_statements`, but also includes information on query plans and wait events for each query type. The statistics is saved into an in-memory ring buffer and is accessible through the `pgpro_stats_statements` view.

By default, `pgpro_stats` collects statistics on all the executed statements that satisfy the `pgpro_stats.track` and `pgpro_stats.track_utility` settings. If performance is a concern, you can set a sample rate for queries using the `pgpro_stats.query_sample_rate` parameter, and `pgpro_stats` will randomly select queries for statistics calculation at the specified rate.

To collect statistics on wait events, `pgpro_stats` uses time-based sampling. Wait events are sampled at the time interval specified by the `pgpro_stats.profile_period` parameter, which is set to 10ms by default. If the sampling shows that the process is waiting, the `pgpro_stats.profile_period` value is added to the wait event duration. Thus, time estimation for each wait event remains valid even if the `pgpro_stats.profile_period` parameter value has changed. If you are not interested in wait event statistics, you can disable wait event sampling by setting the `pgpro_stats.enable_profile` parameter to `false`.

As an example, let's create a table with some random data and build an index on this table:

```
CREATE TABLE test AS (SELECT i, random() x FROM generate_series(1,1000000) i);
CREATE INDEX test_x_idx ON test (x);
```

Now run the following query several times using different values for `:x_min` and `:x_max`:

```
SELECT * from test where x >= :x_min and x <= :x_max;
```

The collected statistics should appear in the `pgpro_stats_statements` view:

```
SELECT queryid, query, planid, plan, wait_stats FROM pgpro_stats_statements WHERE query LIKE 'select * from test where%';
```

As an example, let's create a table with some random data and build an index on this table:

```
CREATE TABLE test AS (SELECT i, random() x FROM generate_series(1,1000000) i);
CREATE INDEX test_x_idx ON test (x);
```

Now run the following query several times using different values for `:x_min` and `:x_max`:

```
SELECT * from test where x >= :x_min and x <= :x_max;
```

The collected statistics should appear in the `pgpro_stats_statements` view:

```
SELECT queryid, query, planid, plan, wait_stats FROM pgpro_stats_statements WHERE query LIKE 'select * from test where%';
```

As an example, let's create a table with some random data and build an index on this table:

```
CREATE TABLE test AS (SELECT i, random() x FROM generate_series(1,1000000) i);
CREATE INDEX test_x_idx ON test (x);
```

Now run the following query several times using different values for `:x_min` and `:x_max`:

```
SELECT * from test where x >= :x_min and x <= :x_max;
```

The collected statistics should appear in the `pgpro_stats_statements` view:

```
SELECT queryid, query, planid, plan, wait_stats FROM pgpro_stats_statements WHERE query LIKE 'select * from test where%';
```

As an example, let's create a table with some random data and build an index on this table:

```
CREATE TABLE test AS (SELECT i, random() x FROM generate_series(1,1000000) i);
CREATE INDEX test_x_idx ON test (x);
```

Now run the following query several times using different values for `:x_min` and `:x_max`:

```
SELECT * from test where x >= :x_min and x <= :x_max;
```

The collected statistics should appear in the `pgpro_stats_statements` view:

```
SELECT queryid, query, planid, plan, wait_stats FROM pgpro_stats_statements WHERE query LIKE 'select * from test where%';
```

As an example, let's create a table with some random data and build an index on this table:

```
CREATE TABLE test AS (SELECT i, random() x FROM generate_series(1,1000000) i);
CREATE INDEX test_x_idx ON test (x);
```

Now run the following query several times using different values for `:x_min` and `:x_max`:

```
SELECT * from test where x >= :x_min and x <= :x_max;
```

The collected statistics should appear in the `pgpro_stats_statements` view:

```
SELECT queryid, query, planid, plan, wait_stats FROM pgpro_stats_statements WHERE query LIKE 'select * from test where%';
```

As an example, let's create a table with some random data and build an index on this table:

```
CREATE TABLE test AS (SELECT i, random() x FROM generate_series(1,1000000) i);
CREATE INDEX test_x_idx ON test (x);
```

Now run the following query several times using different values for `:x_min` and `:x_max`:

```
SELECT * from test where x >= :x_min and x <= :x_max;
```

The collected statistics should appear in the `pgpro_stats_statements` view:

```
SELECT queryid, query, planid, plan, wait_stats FROM pgpro_stats_statements WHERE query LIKE 'select * from test where%';
```

As an example, let's create a table with some random data and build an index on this table:

```
CREATE TABLE test AS (SELECT i, random() x FROM generate_series(1,1000000) i);
CREATE INDEX test_x_idx ON test (x);
```

Now run the following query several times using different values for `:x_min` and `:x_max`:

```
SELECT * from test where x >= :x_min and x <= :x_max;
```

The collected statistics should appear in the `pgpro_stats_statements` view:

```
SELECT queryid, query, planid, plan, wait_stats FROM pgpro_stats_statements WHERE query LIKE 'select * from test where%';
```

As an example, let's create a table with some random data and build an index on this table:

```
CREATE TABLE test AS (SELECT i, random() x FROM generate_series(1,1000000) i);
CREATE INDEX test_x_idx ON test (x);
```

Now run the following query several times using different values for `:x_min` and `:x_max`:

```
SELECT * from test where x >= :x_min and x <= :x_max;
```

The collected statistics should appear in the `pgpro_stats_statements` view:

```
SELECT queryid, query, planid, plan, wait_stats FROM pgpro_stats_statements WHERE query LIKE 'select * from test where%';
```

As an example, let's create a table with some random data and build an index on this table:

```
CREATE TABLE test AS (SELECT i, random() x FROM generate_series(1,1000000) i);
CREATE INDEX test_x_idx ON test (x);
```

Now run the following query several times using different values for `:x_min` and `:x_max`:

```
SELECT * from test where x >= :x_min and x <= :x_max;
```

The collected statistics should appear in the `pgpro_stats_statements` view:

```
SELECT queryid, query, planid, plan, wait_stats FROM pgpro_stats_statements WHERE query LIKE 'select * from test where%';
```

As an example, let's create a table with some random data and build an index on this table:

```
CREATE TABLE test AS (SELECT i, random() x FROM generate_series(1,1000000) i);
CREATE INDEX test_x_idx ON test (x);
```

Now run the following query several times using different values for `:x_min` and `:x_max`:

```
SELECT * from test where x >= :x_min and x <= :x_max;
```

The collected statistics should appear in the `pgpro_stats_statements` view:

```
SELECT queryid, query, planid, plan, wait_stats FROM pgpro_stats_statements WHERE query LIKE 'select * from test where%';
```
Additional Supplied Modules

F.39.3.2. Monitoring Custom Metrics

With pgpro_stats, you can define custom metrics to be monitored. The collected data will be saved into an in-memory ring buffer and then sent to a monitoring system. Unlike direct polling of a database by a monitoring system that can lose some data if the connection is interrupted, this approach allows to get all the collected data regardless of connection issues, as long as this data is still available in the ring buffer.

To set up a custom metric to collect, do the following:

1. For each metric, define all configuration parameters listed in Section F.39.7.2. You must specify a unique numeric identifier of each metric in the parameter names.

   For example, to monitor index bloating each 60 seconds, you can define a new metric by setting metrics-related parameters as follows:

   ```
   pgpro_stats.metric_1_name = index_bloat
   pgpro_stats.metric_1_query = 'select iname, ibloat, ipages from bloat'
   pgpro_stats.metric_1_db = 'postgres'
   pgpro_stats.metric_1_user = postgres
   pgpro_stats.metric_1_period = '60s'
   ```

2. Restart the server.

   pgpro_stats starts collecting statistics on executed statements and saves it into the ring buffer, and the collected data appears in the pgpro_stats_metrics view:

   ```
   SELECT * FROM pgpro_stats_metrics;
   ```

   Once the new metric is added, its parameters can be changed without a server restart by simply reloading the postgresql.conf configuration file.

3. If required, set up data export to a monitoring system of your choice.
F.39.4. Views

F.39.4.1. The `pgpro_stats_statements` View

The statistics gathered by the module are made available via a view named `pgpro_stats_statements`. This view contains one row for each distinct database ID, user ID and query ID (up to the maximum number of distinct statements that the module can track). The columns of the view are shown in Table F.66.

<table>

</tr>
<tr>
<td>cache_resets</td>
<td>int4</td>
<td>Number of shared cache resets (only for cluster, databases and backends)</td>
</tr>
</tbody>
</table>

### F.39.4.3. The pgpro_stats_inval_status View

The `pgpro_stats_inval_status` view shows one row with the current status of the global cache invalidation queue. The columns of the view are shown in Table F.68.

#### Table F.68. pgpro_stats_inval_status Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>num_inval_messages</td>
<td>int8</td>
<td>Number of invalidation messages in the queue</td>
</tr>
<tr>
<td>num_inval_queue_cleanups</td>
<td>int8</td>
<td>Number of invalidation queue cleanups done to prevent its overflow</td>
</tr>
<tr>
<td>num_inval_queue_resets</td>
<td>int4</td>
<td>Number of cache resets for backends that delay the queue cleanup</td>
</tr>
</tbody>
</table>
In a working system, `num_inval_messages` usually approximately equals 4000, which means that the queue is pretty full. Growing `num_inval_queue_cleanups` indicates an active generation of messages. Growth of `num_inval_queue_resets` is normally zero, and a non-zero growth indicates either a too fast generation of messages or delays in processing messages by backends. You can see reset counters for each backend in the `cache_resets` column of the `pgpro_stats_totals` view.

**F.39.4.4. The `pgpro_stats_metrics` View**

The metrics gathered by `pgpro_stats` are displayed in the `pgpro_stats_metrics` view. The table below describes the columns of the view.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>metric_number</td>
<td>int4</td>
<td>A unique ID of the collected metric assigned by user. This ID is included into parameter names that define the metric.</td>
</tr>
<tr>
<td>metric_name</td>
<td>text</td>
<td>The name of the metric defined by the <code>pgpro_stats.metric_name</code> parameter.</td>
</tr>
<tr>
<td>db_name</td>
<td>text</td>
<td>The name of the database for which a particular metric was collected.</td>
</tr>
<tr>
<td>ts</td>
<td>timestamptz</td>
<td>The time when the metric value got calculated.</td>
</tr>
<tr>
<td>value</td>
<td>jsonb</td>
<td>The result of the query used for metric measurement. It is serialized in <code>jsonb</code> as an array of objects received via <code>to_jsonb(resulting_row)</code>. If an error occurs, a single object is returned that contains <code>code</code>, <code>message</code>, <code>detail</code>, and <code>hint</code> fields.</td>
</tr>
</tbody>
</table>

**F.39.5. Data Types**

**F.39.5.1. The `pgpro_stats_rusage` Type**

`pgpro_stats_rusage` is a record type that contains resource usage statistics of statement planning/execution. The fields of this type are shown in Table F.70.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>reads</td>
<td>bigint</td>
<td>Number of bytes read by the filesystem layer</td>
</tr>
<tr>

<td>bigint</td>
<td>Number of relation map invalidation messages</td>
</tr>
<tr>
<td>snapshot</td>
<td>bigint</td>
<td>Number of snapshot invalidation messages</td>
</tr>
</tbody>
</table>

#### F.39.6. Functions

`pgpro_stats_statements_reset` (userid Oid, dbid Oid, queryid bigint, planid bigint) returns void

`pgpro_stats_statements_reset` discards statistics gathered so far by `pgpro_stats` corresponding to the specified userid, dbid, queryid, and planid. If any of the parameters are not specified, the default value 0(invalid) is used for each of them and the statistics that match with other parameters will be reset. If no parameter is specified or all the specified parameters are 0(invalid), it will discard all statistics. By default, this function can only be executed by superusers. Access may be granted to others using `GRANT`.

`pgpro_stats_statements` (showtext boolean) returns setof record

The `pgpro_stats_statements` view is defined in terms of a function also named `pgpro_stats_statements`. Users can also call the `pgpro_stats_statements` function directly, and by specifying `showtext := false` make query text be omitted (that is, the `OUT` argument that corresponds to the view's `query` column will return nulls). This feature is intended to support external
tools that might wish to avoid the overhead of repeatedly retrieving query texts of indeterminate length. Such tools can instead cache the first query text observed for each entry themselves, since that is all `pgpro_stats` itself does, and then retrieve query texts only as needed. Since the server stores query texts in a file, this approach may reduce physical I/O for repeated examination of the `pgpro_stats_statements` data.

```sql
pgpro_stats_totals_reset(type text, id bigint) returns void
```

`pgpro_stats_totals_reset` discards statistics gathered so far by `pgpro_stats` corresponding to the specified object `type` and `id`. If no parameter is specified or the `type` parameter is set to 0, all statistics will be discarded. If `type` is set to a valid object type, then if `id` is specified, then statistics will be discarded only for the specified object, else, statistics will be discarded for all objects of the specified type. Otherwise, no statistics will be discarded. By default, this function can only be executed by superusers. Access may be granted to others using `GRANT`.

```sql
pgpro_stats_totals() returns setof record
```

The `pgpro_stats_totals` view is defined in terms of a function also named `pgpro_stats_totals`. Users can also call the `pgpro_stats_totals` function directly.

```sql
pgpro_stats_metrics(showtext boolean) returns setof record
```

Defines the `pgpro_stats_metrics` view, which is described in detail in Table F.69.

### F.39.7. Configuration Parameters

#### F.39.7.1. General Settings

```sql
pgpro_stats.max(integer)
```

`pgpro_stats.max` is the maximum number of statements tracked by the module (i.e., the maximum number of rows in the `pgpro_stats_statements` view). If more distinct statements than that are observed, information about the least-executed statements is discarded. The default value is 5000. This parameter can only be set at server start.

```sql
pgpro_stats.max_totals(integer)
```

`pgpro_stats.max_totals` is the maximum number of objects tracked by the module (i.e., the maximum number of rows in the `pgpro_stats_totals` view). If more distinct objects than that are observed, information about least-used objects is discarded. The default value is 1000. This parameter can only be set at server start.

```sql
pgpro_stats.track(enum)
```

`pgpro_stats.track` controls which statements are counted by the module. Specify `top` to track top-level statements (those issued directly by clients), `all` to also track nested statements (such as statements invoked within functions), or `none` to disable statement statistics collection. The default value is `top`. Only superusers can change this setting.

```sql
pgpro_stats.track_utility(boolean)
```

`pgpro_stats.track_utility` controls whether utility commands are tracked by the module. Utility commands are all those other than `SELECT`, `INSERT`, `UPDATE` and `DELETE`. The default value is `on`. Only superusers can change this setting.

```sql
pgpro_stats.track_planning(boolean)
```

`pgpro_stats.track_planning` controls whether planning operations and duration are tracked by the module. Enabling this parameter may incur a noticeable performance penalty, especially when statements with identical query structure are executed by many concurrent connections which compete to update a small number of `pg_stat_statements` entries. The default value is `off`. Only superusers can change this setting.
pgpro_stats.track_totals (boolean)

pgpro_stats.track_totals controls whether aggregate statistics for objects (cluster, users, databases etc.) are tracked by the module. The default value is on. Only superusers can change this setting.

pgpro_stats.track_cluster (boolean)

pgpro_stats.track_cluster controls whether aggregate statistics for the cluster are tracked by the module. The default value is on. Only superusers can change this setting.

pgpro_stats.track_databases (boolean)

pgpro_stats.track_databases controls whether aggregate statistics for the databases are tracked by the module. The default value is on. Only superusers can change this setting.

pgpro_stats.track_users (boolean)

pgpro_stats.track_users controls whether aggregate statistics for the users are tracked by the module. The default value is on. Only superusers can change this setting.

pgpro_stats.track_applications (boolean)

pgpro_stats.track_applications controls whether aggregate statistics for the applications (whose names are set by application_name) are tracked by the module. The default value is on. Only superusers can change this setting.

pgpro_stats.track_client_addr (boolean)

pgpro_stats.track_client_addr controls whether aggregate statistics for the client IP addresses are tracked by the module. The default value is on. Only superusers can change this setting.

pgpro_stats.track_backends (boolean)

pgpro_stats.track_backends controls whether aggregate statistics for the backends are tracked by the module. The default value is on. Only superusers can change this setting.

pgpro_stats.track_sessions (boolean)

pgpro_stats.track_sessions controls whether aggregate statistics for the sessions are tracked by the module. The default value is on. Only superusers can change this setting.

pgpro_stats.save (boolean)

pgpro_stats.save specifies whether to save statement statistics across server shutdowns. If it is off then statistics are neither saved at shutdown nor reloaded at server start. The default value is on. This parameter can only be set in the postgresql.conf file or on the server command line.

pgpro_stats.plan_format (text)

pgpro_stats.plan_format selects the EXPLAIN format for the query plan. Possible values are text, xml, json, and yaml. The default value is text. Changing this parameter requires a server restart.

pgpro_stats.enable_profile (boolean)

pgpro_stats.enable_profile enables sampling of wait events for separate statements. The default value is true. Changing this parameter requires a server restart.

pgpro_stats.query_sample_rate (float)

pgpro_stats.query_sample_rate specifies the fraction of queries that are randomly selected for statistics calculation. Possible values lie between 0.0 (no queries) and 1.0 (all queries). The default value is 1.0. Changing this parameter requires a server restart.

pgpro_stats.profile_period (integer)

pgpro_stats.profile_period specifies the period, in milliseconds, during which to sample wait events. The default value is 10. Only superusers can change this setting.
Additional Supplied Modules

pgpro_stats.metrics_buffer_size (integer)

pgpro_stats.metrics_buffer_size specifies the size of the ring buffer used for collecting statistical metrics. The default value is 16kB. Changing this parameter requires a server restart.

pgpro_stats.metrics_workers (integer)

pgpro_stats.metrics_workers specifies the number of workers used to collect statistical metrics. If this parameter is set to 2 or higher, one of the workers serves as the master worker distributing queries to other workers. If only one worker is available, it gets reloaded to connect to different databases. Setting this parameter to 0 disables metrics collection. The default value is 2. Changing this parameter requires a server restart.

F.39.7.2. Metrics Settings

The following parameters can be used to define a custom metric to collect. The \( N \) placeholder in the parameter name serves as a unique identifier of the metric to which this setting should apply; it must be set to a non-negative integer for each metric.

When you add these parameters for a new metric, you have to restart the server for the changes to take effect. Once the new metric is added, its parameters can be changed without a server restart by simply reloading the `postgresql.conf` configuration file.

pgpro_stats.metric_\( N \)_name (text)

The name of metric \( N \). This name will be displayed in the `metric_name` column of the `pgpro_stats_metrics` view.

pgpro_stats.metric_\( N \)_query (text)

The query statement that defines the metric to collect.

pgpro_stats.metric_\( N \)_period (integer)

The time interval at which to collect metric \( N \), in milliseconds. Default: 60000 ms

pgpro_stats.metric_\( N \)_db (text)

The list of databases for which to collect metric \( N \). Database names must be separated by commas. You can specify the \(*\) character to select all databases in the cluster except the template databases. If you need to analyze the template databases as well, you have to specify them explicitly.

pgpro_stats.metric_\( N \)_user (text)

The name of the user on behalf of which to collect metric \( N \). This user must have access to the database for which the metric is collected.

F.39.8. Authors

Postgres Professional, Moscow, Russia

F.40. pg_query_state

The `pg_query_state` module provides facility to know the current state of query execution on working backend.

F.40.1. Overview

Each non-utility query statement (SELECT/INSERT/UPDATE/DELETE) after optimization/planning stage is translated into plan tree, which is kind of imperative representation of declarative SQL query. EXPLAIN ANALYZE request allows to demonstrate execution statistics gathered from each node of plan tree (full time of execution, number of rows emitted to upper nodes, etc). But this statistics is collected after execution of query. This module allows to show actual statistics of query running on external backend. At that, format of resulting output is almost identical to ordinal EXPLAIN ANALYZE. Thus users are able to track of query execution in progress. In fact, this module is able to explore external backend and determine its actual state. Particularly it's helpful when backend executes a heavy query or gets stuck.
F.40.2. Use cases

Using this module there can help in the following things:

- detect a long query (along with other monitoring tools);
- supervise query execution.

F.40.3. Installation

To install `pg_query_state` run in `psql`:

```
CREATE EXTENSION pg_query_state;
```

Then modify `shared_preload_libraries` parameter in `postgres.conf` as following:

```
shared_preload_libraries = 'pg_query_state'
```

It will require to restart the Postgres Pro instance.

F.40.4. Function `pg_query_state`

```
pg_query_state(integer  pid,
    verbose  boolean DEFAULT FALSE,
    costs    boolean DEFAULT FALSE,
    timing   boolean DEFAULT FALSE,
    buffers  boolean DEFAULT FALSE,
    triggers boolean DEFAULT FALSE,
    format   text    DEFAULT 'text')
returns TABLE (pid integer,
    frame_number integer,
    query_text text,
    plan text,
    leader_pid integer)
```

Extract current query state from backend with specified `pid`. Since parallel query can spawn multiple workers and function call causes nested subqueries so that state of execution may be viewed as stack of running queries, return value of `pg_query_state` has type `TABLE (pid integer, frame_number integer, query_text text, plan text, leader_pid integer)`. It represents tree structure consisting of leader process and its spawned workers identified by `pid`. Each worker refers to leader through `leader_pid` column. For leader process the value of this column is `null`. The state of each process is represented as stack of function calls. Each frame of that stack is specified as correspondence between `frame_number` starting from zero, `query_text` and `plan` with online statistics columns.

Thus, user can see the states of main query and queries generated from function calls for leader process and all workers spawned from it.

In process of execution some nodes of plan tree can take loops of full execution. Therefore statistics for each node consists of two parts: average statistics for previous loops just like in `EXPLAIN ANALYZE` output and statistics for current loop if node have not finished.

Optional arguments:

- `verbose` - use `EXPLAIN VERBOSE` for plan printing;
- `costs` - costs for each node;
- `timing` - print timing data for each node, if collecting of timing statistics is turned off on called side resulting output will contain WARNING message `timing statistics disabled`;
- `buffers` - print buffers usage, if collecting of buffers statistics is turned off on called side resulting output will contain WARNING message `buffers statistics disabled`;
- `triggers` - include triggers statistics in result plan trees;
- `format` - `EXPLAIN` format to be used for plans printing, possible values: `text`, `xml`, `json`, `yaml`. 
If callable backend is not executing any query the function prints INFO message about backend’s state taken from `pg_stat_activity` view if it exists there.

Calling role have to be superuser or member of the role whose backend is being called. Otherwise function prints ERROR message permission denied.

### F.40.5. Configuration settings

There are several user-accessible GUC variables designed to toggle the whole module and the collecting of specific statistic parameters while query is running:

- `pg_query_state.enable` - disable (or enable) `pg_query_state` completely, default value is `true`
- `pg_query_state.enable_timing` - collect timing data for each node, default value is `false`
- `pg_query_state.enable_buffers` - collect buffers usage, default value is `false`

These parameters are set on called side before running any queries whose states are attempted to extract. **WARNING:** if `pg_query_state.enable_timing` is turned off the calling side cannot get time statistics, similarly for `pg_query_state.enable_buffers` parameter.

### F.40.6. Examples

Set maximum number of parallel workers on `gather` node equals 2:

```sql
postgres=\# set max_parallel_workers_per_gather = 2;
```

Assume one backend with `pid = 49265` performs a simple query:

```sql
postgres=# select pg_backend_pid();
pg_backend_pid
------------------
    49265
(1 row)
```

```sql
postgres=# select count(*) from foo join bar on foo.c1=bar.c1;
```

Other backend can extract intermediate state of execution that query:

```sql
postgres=# \x
postgres=# select * from pg_query_state(49265);
```

```
<table>
<thead>
<tr>
<th>pid</th>
<th>49265</th>
</tr>
</thead>
<tbody>
<tr>
<td>frame_number</td>
<td>0</td>
</tr>
<tr>
<td>query_text</td>
<td>select count(*) from foo join bar on foo.c1=bar.c1;</td>
</tr>
<tr>
<td>plan</td>
<td>Finalize Aggregate (Current loop: actual rows=0, loop number=1)</td>
</tr>
<tr>
<td></td>
<td>-&gt; Gather (Current loop: actual rows=0, loop number=1)</td>
</tr>
<tr>
<td></td>
<td>Workers Planned: 2</td>
</tr>
<tr>
<td></td>
<td>Workers Launched: 2</td>
</tr>
<tr>
<td></td>
<td>-&gt; Partial Aggregate (Current loop: actual rows=0, loop number=1)</td>
</tr>
<tr>
<td>number=1</td>
<td>-&gt; Nested Loop (Current loop: actual rows=12, loop number=1)</td>
</tr>
<tr>
<td></td>
<td>Join Filter: (foo.c1 = bar.c1)</td>
</tr>
<tr>
<td></td>
<td>Rows Removed by Join Filter: 5673232</td>
</tr>
</tbody>
</table>
```
In example above working backend spawns two parallel workers with pids 49324 and 49323. Their `leader_pid` column’s values clarify that these workers belong to the main backend. Seq Scan node has statistics on passed loops (average number of rows delivered to Nested Loop and number of passed loops are shown) and statistics on current loop. Other nodes has statistics only for current loop as this loop is first (loop number = 1).

Assume first backend executes some function:

```sql
postgres=# select n_join_foo_bar();
```

Other backend can get the follow output:

```sql
postgres=# select * from pg_query_state(49265);
```
### Additional Supplied Modules

| frame_number | 0 |
| query_text   | select n_join_foo_bar(); |
| plan         | Result (Current loop: actual rows=0, loop number=1) |
| leader_pid   | (null) |

- \[ RECORD 2 \]+

| pid          | 49265 |
| frame_number | 1 |
| query_text   | SELECT (select count(*) from foo join bar on foo.c1=bar.c1) |
| plan         | Result (Current loop: actual rows=0, loop number=1) |

  + InitPlan 1 (returns $0) |

  + -> Aggregate (Current loop: actual rows=0, loop number=1) |

  + -> Nested Loop (Current loop: actual rows=51, loop number=1) |

  + Join Filter: (foo.c1 = bar.c1) |

  + Rows Removed by Join Filter: 51636304 |

  + -> Seq Scan on bar (Current loop: actual rows=52, loop number=1) |

  + -> Materialize (actual rows=1000000 loops=51) (Current loop: actual rows=636355, loop number=52) |

  + -> Seq Scan on foo (Current loop: actual rows=1000000, loop number=1) |

| leader_pid   | (null) |

First row corresponds to function call, second - to query which is in the body of that function.

We can get result plans in different format (e.g. json):

```
postgres=# select * from pg_query_state(pid := 49265, format := 'json');
-\[ RECORD 1 \]+

| pid          | 49265 |
| frame_number | 0 |
| query_text   | select * from n_join_foo_bar(); |
| plan         | { |
|             |   "Plan": { |
|             |     "Node Type": "Function Scan", |
|             |     "Parallel Aware": false, |
|             |     "Function Name": "n_join_foo_bar", |
|             |     "Alias": "n_join_foo_bar", |
|             |     "Current loop": { |
|             |       "Actual Loop Number": 1, |
|             |       "Actual Rows": 0 |
|             |   } |
|             | } |

leader_pid | (null) |

-\[ RECORD 2 \]+

| pid          | 49265 |
| frame_number | 1 |
| query_text   | SELECT (select count(*) from foo join bar on foo.c1=bar.c1) |
| plan         | { |
|             |   "Plan": { |
|             |     "Node Type": "Result", |
|             | } |
```

            }
          },
          {
            "Node Type": "Seq Scan",
            "Parent Relationship": "Outer",
            "Parallel Aware": false,
            "Relation Name": "foo",
            "Alias": "foo",
            "Plans": []
          }
        ]
      }
    ]
  }
]
F.41. pgrowlocks

The pgrowlocks module provides a function to show row locking information for a specified table.

By default use is restricted to superusers, members of the pg_stat_scan_tables role, and users with SELECT permissions on the table.

F.41.1. Overview

pgrowlocks(text) returns setof record

The parameter is the name of a table. The result is a set of records, with one row for each locked row within the table. The output columns are shown in Table F.72.

Table F.72. pgrowlocks Output Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>locked_row</td>
<td>tid</td>
<td>Tuple ID (TID) of locked row</td>
</tr>
<tr>
<td>locker</td>
<td>xid</td>
<td>Transaction ID of locker, or multixact ID if multitransaction</td>
</tr>
<tr>
<td>multi</td>
<td>boolean</td>
<td>True if locker is a multitransaction</td>
</tr>
<tr>
<td>xids</td>
<td>xid[]</td>
<td>Transaction IDs of lockers (more than one if multitransaction)</td>
</tr>
<tr>
<td>modes</td>
<td>text[]</td>
<td>Lock mode of lockers (more than one if multitransaction), an array of Key Share, Share, For No Key Update, No Key Update, For Update, Update.</td>
</tr>
<tr>
<td>pids</td>
<td>integer[]</td>
<td>Process IDs of locking backends (more than one if multitransaction)</td>
</tr>
</tbody>
</table>

pgrowlocks takes AccessShareLock for the target table and reads each row one by one to collect the row locking information. This is not very speedy for a large table. Note that:

1. If an ACCESS EXCLUSIVE lock is taken on the table, pgrowlocks will be blocked.
2. pgrowlocks is not guaranteed to produce a self-consistent snapshot. It is possible that a new row lock is taken, or an old lock is freed, during its execution.

pgrowlocks does not show the contents of locked rows. If you want to take a look at the row contents at the same time, you could do something like this:
Additional Supplied Modules
SELECT * FROM accounts AS a, pgrowlocks('accounts') AS p
WHERE p.locked_row = a.ctid;
Be aware however that such a query will be very ineﬀicient.

F.41.2. Sample Output
=# SELECT * FROM pgrowlocks('t1');
locked_row | locker | multi | xids |
modes
| pids
------------+--------+-------+-------+----------------+-------(0,1)
|
609 | f
| {609} | {"For Share"} | {3161}
(0,2)
|
609 | f
| {609} | {"For Share"} | {3161}
(0,3)
|
607 | f
| {607} | {"For Update"} | {3107}
(0,4)
|
607 | f
| {607} | {"For Update"} | {3107}
(4 rows)

F.41.3. Author
Tatsuo Ishii

F.42. pg_stat_statements
The pg_stat_statements module provides a means for tracking planning and execution statistics of all
SQL statements executed by a server.
The module must be loaded by adding pg_stat_statements to shared_preload_libraries in
postgresql.conf, because it requires additional shared memory. This means that a server restart is
needed to add or remove the module. In addition, query identiﬁer calculation must be enabled in order
for the module to be active, which is done automatically if compute_query_id is set to auto or on, or any
third-party module that calculates query identiﬁers is loaded.
When pg_stat_statements is active, it tracks statistics across all databases of the server.
To access and manipulate these statistics, the module provides views pg_stat_statements
and pg_stat_statements_info, and the utility functions pg_stat_statements_reset and
pg_stat_statements. These are not available globally but can be enabled for a speciﬁc database with
CREATE EXTENSION pg_stat_statements.

F.42.1. The pg_stat_statements View
The statistics gathered by the module are made available via a view named pg_stat_statements. This
view contains one row for each distinct combination of database ID, user ID, query ID and whether it's a
top-level statement or not (up to the maximum number of distinct statements that the module can track).
The columns of the view are shown in Table F.73.
Table F.73. pg_stat_statements Columns

Column Type
Description
userid oid (references pg_authid .oid)
OID of user who executed the statement
dbid oid (references pg_database .oid)
OID of database in which the statement was executed
toplevel bool
True if the query was executed as a top-level statement (always true if pg_stat_
statements.track is set to top)
queryid bigint
Hash code to identify identical normalized queries.
query text
Text of a representative statement
2435

For security reasons, only superusers and members of the `pg_read_all_stats` role are allowed to see the SQL text and `query_id` of queries executed by other users. Other users can see the statistics, however, if the view has been installed in their database.

Plannable queries (that is, `SELECT`, `INSERT`, `UPDATE`, and `DELETE`) are combined into a single `pg_stat_statements` entry whenever they have identical query structures according to an internal hash calculation. Typically, two queries will be considered the same for this purpose if they are semantically equivalent except for the values of literal constants appearing in the query. Utility commands (that is, all other commands) are compared strictly on the basis of their textual query strings, however.

**Note**

The following details about constant replacement and `query_id` only apply when `compute_query_id` is enabled. If you use an external module instead to compute `query_id`, you should refer to its documentation for details.

When a constant’s value has been ignored for purposes of matching the query to other queries, the constant is replaced by a parameter symbol, such as `$1`, in the `pg_stat_statements` display. The rest of the query text is that of the first query that had the particular `query_id` hash value associated with the `pg_stat_statements` entry.

In some cases, queries with visibly different texts might get merged into a single `pg_stat_statements` entry. Normally this will happen only for semantically equivalent queries, but there is a small chance of hash collisions causing unrelated queries to be merged into one entry. (This cannot happen for queries belonging to different users or databases, however.)

Since the `query_id` hash value is computed on the post-parse-analysis representation of the queries, the opposite is also possible: queries with identical texts might appear as separate entries, if they have different meanings as a result of factors such as different `search_path` settings.

Consumers of `pg_stat_statements` may wish to use `query_id` (perhaps in combination with `dbid` and `userid`) as a more stable and reliable identifier for each entry than its query text. However, it is important to understand that there are only limited guarantees around the stability of the `query_id` hash value.
Since the identifier is derived from the post-parse-analysis tree, its value is a function of, among other things, the internal object identifiers appearing in this representation. This has some counterintuitive implications. For example, `pg_stat_statements` will consider two apparently-identical queries to be distinct, if they reference a table that was dropped and recreated between the executions of the two queries. The hashing process is also sensitive to differences in machine architecture and other facets of the platform. Furthermore, it is not safe to assume that `queryid` will be stable across major versions of Postgres Pro.

As a rule of thumb, `queryid` values can be assumed to be stable and comparable only so long as the underlying server version and catalog metadata details stay exactly the same. Two servers participating in replication based on physical WAL replay can be expected to have identical `queryid` values for the same query. However, logical replication schemes do not promise to keep replicas identical in all relevant details, so `queryid` will not be a useful identifier for accumulating costs across a set of logical replicas. If in doubt, direct testing is recommended.

The parameter symbols used to replace constants in representative query texts start from the next number after the highest $n$ parameter in the original query text, or $1$ if there was none. It’s worth noting that in some cases there may be hidden parameter symbols that affect this numbering. For example, PL/pgSQL uses hidden parameter symbols to insert values of function local variables into queries, so that a PL/pgSQL statement like `SELECT i + 1 INTO j` would have representative text like `SELECT i + $2`.

The representative query texts are kept in an external disk file, and do not consume shared memory. Therefore, even very lengthy query texts can be stored successfully. However, if many long query texts are accumulated, the external file might grow unmanageably large. As a recovery method if that happens, `pg_stat_statements` may choose to discard the query texts, whereupon all existing entries in the `pg_stat_statements` view will show null `query` fields, though the statistics associated with each `queryid` are preserved. If this happens, consider reducing `pg_stat_statements.max` to prevent recurrences.

`plans` and `calls` aren’t always expected to match because planning and execution statistics are updated at their respective end phase, and only for successful operations. For example, if a statement is successfully planned but fails during the execution phase, only its planning statistics will be updated. If planning is skipped because a cached plan is used, only its execution statistics will be updated.

### F.42.2. The `pg_stat_statements_info` View

The statistics of the `pg_stat_statements` module itself are tracked and made available via a view named `pg_stat_statements_info`. This view contains only a single row. The columns of the view are shown in Table F.74.

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dealloc</code> bigint</td>
<td>Total number of times <code>pg_stat_statements</code> entries about the least-executed statements were deallocated because more distinct statements than <code>pg_stat_statements.max</code> were observed</td>
</tr>
<tr>
<td><code>stats_reset</code> timestamp with time zone</td>
<td>Time at which all statistics in the <code>pg_stat_statements</code> view were last reset.</td>
</tr>
</tbody>
</table>

### F.42.3. Functions

```sql
pg_stat_statements_reset(userid Oid, dbid Oid, queryid bigint) returns void
```

`pg_stat_statements_reset` discards statistics gathered so far by `pg_stat_statements` corresponding to the specified `userid`, `dbid` and `queryid`. If any of the parameters are not specified, the default value 0 (invalid) is used for each of them and the statistics that match with other parameters will be reset. If no parameter is specified or all the specified parameters are 0 (invalid),
it will discard all statistics. If all statistics in the \texttt{pg_stat_statements} view are discarded, it will also reset the statistics in the \texttt{pg_stat_statements_info} view. By default, this function can only be executed by superusers. Access may be granted to others using \texttt{GRANT}.

\begin{verbatim}
pg_stat_statements(showtext boolean) returns setof record
The \texttt{pg_stat_statements} view is defined in terms of a function also named \texttt{pg_stat_statements}. It is possible for clients to call the \texttt{pg_stat_statements} function directly, and by specifying \texttt{showtext := false} have query text be omitted (that is, the OUT argument that corresponds to the view's query column will return nulls). This feature is intended to support external tools that might wish to avoid the overhead of repeatedly retrieving query texts of indeterminate length. Such tools can instead cache the first query text observed for each entry themselves, since that is all \texttt{pg_stat_statements} itself does, and then retrieve query texts only as needed. Since the server stores query texts in a file, this approach may reduce physical I/O for repeated examination of the \texttt{pg_stat_statements} data.
\end{verbatim}

\section*{F.42.4. Configuration Parameters}

\begin{verbatim}
pagetic{pg_stat_statements.max (integer)}
pagetic{pg_stat_statements.max} is the maximum number of statements tracked by the module (i.e., the maximum number of rows in the \texttt{pg_stat_statements} view). If more distinct statements than that are observed, information about the least-executed statements is discarded. The number of times such information was discarded can be seen in the \texttt{pg_stat_statements_info} view. The default value is 5000. This parameter can only be set at server start.

\begin{verbatim}
pagetic{pg_stat_statements.track (enum)}
pagetic{pg_stat_statements.track} controls which statements are counted by the module. Specify \texttt{top} to track top-level statements (those issued directly by clients), \texttt{all} to also track nested statements (such as statements invoked within functions), or \texttt{none} to disable statement statistics collection. The default value is \texttt{top}. Only superusers can change this setting.

\begin{verbatim}
pagetic{pg_stat_statements.track_utility (boolean)}
pagetic{pg_stat_statements.track_utility} controls whether utility commands are tracked by the module. Utility commands are all those other than SELECT, INSERT, UPDATE and DELETE. The default value is \texttt{on}. Only superusers can change this setting.

\begin{verbatim}
pagetic{pg_stat_statements.track_planning (boolean)}
pagetic{pg_stat_statements.track_planning} controls whether planning operations and duration are tracked by the module. Enabling this parameter may incur a noticeable performance penalty, especially when statements with identical query structure are executed by many concurrent connections which compete to update a small number of \texttt{pg_stat_statements} entries. The default value is \texttt{off}. Only superusers can change this setting.

\begin{verbatim}
pagetic{pg_stat_statements.save (boolean)}
pagetic{pg_stat_statements.save} specifies whether to save statement statistics across server shutdowns. If it is \texttt{off} then statistics are not saved at shutdown nor reloaded at server start. The default value is \texttt{on}. This parameter can only be set in the \texttt{postgresql.conf} file or on the server command line.

The module requires additional shared memory proportional to \texttt{pg_stat_statements.max}. Note that this memory is consumed whenever the module is loaded, even if \texttt{pg_stat_statements.track} is set to \texttt{none}.

These parameters must be set in \texttt{postgresql.conf}. Typical usage might be:
\begin{verbatim}
# postgresql.conf
shared_preload_libraries = 'pg_stat_statements'

compute_query_id = on
pg_stat_statements.max = 10000
\end{verbatim}
\end{verbatim}
F.42.5. Sample Output

F.42.6. Authors

Takahiro Itagaki <itagaki.takahiro@oss.ntt.co.jp>. Query normalization added by Peter Geoghegan <peter@2ndquadrant.com>.

F.43. pgstattuple

The pgstattuple module provides various functions to obtain tuple-level statistics.
Because these functions return detailed page-level information, access is restricted by default. By default, only the role `pg_stat_scan_tables` has EXECUTE privilege. Superusers of course bypass this restriction. After the extension has been installed, users may issue `GRANT` commands to change the privileges on the functions to allow others to execute them. However, it might be preferable to add those users to the `pg_stat_scan_tables` role instead.

### F.43.1. Functions

`pgstattuple(regclass) returns record`

`pgstattuple` returns a relation's physical length, percentage of "dead" tuples, and other info. This may help users to determine whether vacuum is necessary or not. The argument is the target relation's name (optionally schema-qualified) or OID. For example:

```sql
test=> SELECT * FROM pgstattuple('pg_catalog.pg_proc');
- [ RECORD 1 ]---------
table_len          | 458752
tuple_count        | 1470
tuple_len          | 438896
tuple_percent      | 95.67
dead_tuple_count   | 11
dead_tuple_len     | 3157
dead_tuple_percent | 0.69
free_space         | 8932
free_percent       | 1.95
```

The output columns are described in Table F.75.

**Table F.75. pgstattuple Output Columns**

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table_len</td>
<td>bigint</td>
<td>Physical relation length in bytes</td>
</tr>
<tr>
<td>tuple_count</td>
<td>bigint</td>
<td>Number of live tuples</td>
</tr>
<tr>
<td>tuple_len</td>
<td>bigint</td>
<td>Total length of live tuples in bytes</td>
</tr>
<tr>
<td>tuple_percent</td>
<td>float8</td>
<td>Percentage of live tuples</td>
</tr>
<tr>
<td>dead_tuple_count</td>
<td>bigint</td>
<td>Number of dead tuples</td>
</tr>
<tr>
<td>dead_tuple_len</td>
<td>bigint</td>
<td>Total length of dead tuples in bytes</td>
</tr>
<tr>
<td>dead_tuple_percent</td>
<td>float8</td>
<td>Percentage of dead tuples</td>
</tr>
<tr>
<td>free_space</td>
<td>bigint</td>
<td>Total free space in bytes</td>
</tr>
<tr>
<td>free_percent</td>
<td>float8</td>
<td>Percentage of free space</td>
</tr>
</tbody>
</table>

**Note**

The `table_len` will always be greater than the sum of the `tuple_len`, `dead_tuple_len` and `free_space`. The difference is accounted for by fixed page overhead, the per-page table of pointers to tuples, and padding to ensure that tuples are correctly aligned.

`pgstattuple` acquires only a read lock on the relation. So the results do not reflect an instantaneous snapshot; concurrent updates will affect them.

`pgstattuple` judges a tuple is "dead" if `HeapTupleSatisfiesDirty` returns false.
pgstattuple(text) returns record

This is the same as pgstattuple(regclass), except that the target relation is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

pgstatindex(regclass) returns record

pgstatindex returns a record showing information about a B-tree index. For example:

    test=> SELECT * FROM pgstatindex('pg_cast_oid_index');
    -[ RECORD 1 ]----------
        version   | 2
        tree_level | 0
        index_size | 16384
        root_block_no | 1
        internal_pages | 0
        leaf_pages | 1
        empty_pages | 0
        deleted_pages | 0
        avg_leaf_density | 54.27
        leaf_fragmentation | 0

The output columns are:

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>version</td>
<td>integer</td>
<td>B-tree version number</td>
</tr>
<tr>
<td>tree_level</td>
<td>integer</td>
<td>Tree level of the root page</td>
</tr>
<tr>
<td>index_size</td>
<td>bigint</td>
<td>Total index size in bytes</td>
</tr>
<tr>
<td>root_block_no</td>
<td>bigint</td>
<td>Location of root page (zero if none)</td>
</tr>
<tr>
<td>internal_pages</td>
<td>bigint</td>
<td>Number of “internal” (upper-level) pages</td>
</tr>
<tr>
<td>leaf_pages</td>
<td>bigint</td>
<td>Number of leaf pages</td>
</tr>
<tr>
<td>empty_pages</td>
<td>bigint</td>
<td>Number of empty pages</td>
</tr>
<tr>
<td>deleted_pages</td>
<td>bigint</td>
<td>Number of deleted pages</td>
</tr>
<tr>
<td>avg_leaf_density</td>
<td>float8</td>
<td>Average density of leaf pages</td>
</tr>
<tr>
<td>leaf_fragmentation</td>
<td>float8</td>
<td>Leaf page fragmentation</td>
</tr>
</tbody>
</table>

The reported index_size will normally correspond to one more page than is accounted for by internal_pages + leaf_pages + empty_pages + deleted_pages, because it also includes the index's metapage.

As with pgstattuple, the results are accumulated page-by-page, and should not be expected to represent an instantaneous snapshot of the whole index.

pgstatindex(text) returns record

This is the same as pgstatindex(regclass), except that the target index is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

pgstatginindex(regclass) returns record

pgstatginindex returns a record showing information about a GIN index. For example:

    test=> SELECT * FROM pgstatginindex('test_gin_index');
    -[ RECORD 1 ]--------
version | 1
pending_pages | 0
pending_tuples | 0

The output columns are:

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>version</td>
<td>integer</td>
<td>GIN version number</td>
</tr>
<tr>
<td>pending_pages</td>
<td>integer</td>
<td>Number of pages in the pending list</td>
</tr>
<tr>
<td>pending_tuples</td>
<td>bigint</td>
<td>Number of tuples in the pending list</td>
</tr>
</tbody>
</table>

pgstathashindex(regclass) returns record

pgstathashindex returns a record showing information about a HASH index. For example:

test=> select * from pgstathashindex('con_hash_index');
- [ RECORD 1 ]--
version        | 4
bucket_pages   | 33081
overflow_pages | 0
bitmap_pages   | 1
unused_pages   | 32455
live_items     | 10204006
dead_items     | 0
free_percent   | 61.8005949100872

The output columns are:

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>version</td>
<td>integer</td>
<td>HASH version number</td>
</tr>
<tr>
<td>bucket_pages</td>
<td>bigint</td>
<td>Number of bucket pages</td>
</tr>
<tr>
<td>overflow_pages</td>
<td>bigint</td>
<td>Number of overflow pages</td>
</tr>
<tr>
<td>bitmap_pages</td>
<td>bigint</td>
<td>Number of bitmap pages</td>
</tr>
<tr>
<td>unused_pages</td>
<td>bigint</td>
<td>Number of unused pages</td>
</tr>
<tr>
<td>live_items</td>
<td>bigint</td>
<td>Number of live tuples</td>
</tr>
<tr>
<td>dead_tuples</td>
<td>bigint</td>
<td>Number of dead tuples</td>
</tr>
<tr>
<td>free_percent</td>
<td>float</td>
<td>Percentage of free space</td>
</tr>
</tbody>
</table>

pg_relpages(regclass) returns bigint

pg_relpages returns the number of pages in the relation.

pg_relpages(text) returns bigint

This is the same as pg_relpages(regclass), except that the target relation is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

pgstattuple_approx(regclass) returns record

pgstattuple_approx is a faster alternative to pgstattuple that returns approximate results. The argument is the target relation's name or OID. For example:

test=> SELECT * FROM pgstattuple_approx('pg_catalog.pg_proc'::regclass);
- [ RECORD 1 ]--------
Additional Supplied Modules

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table_len</td>
<td>bigint</td>
<td>Physical relation length in bytes (exact)</td>
</tr>
<tr>
<td>scanned_percent</td>
<td>float8</td>
<td>Percentage of table scanned</td>
</tr>
<tr>
<td>approx_tuple_count</td>
<td>bigint</td>
<td>Number of live tuples (estimated)</td>
</tr>
<tr>
<td>approx_tuple_len</td>
<td>bigint</td>
<td>Total length of live tuples in bytes (estimated)</td>
</tr>
<tr>
<td>approx_tuple_percent</td>
<td>float8</td>
<td>Percentage of live tuples</td>
</tr>
<tr>
<td>dead_tuple_count</td>
<td>bigint</td>
<td>Number of dead tuples (exact)</td>
</tr>
<tr>
<td>dead_tuple_len</td>
<td>bigint</td>
<td>Total length of dead tuples in bytes (exact)</td>
</tr>
<tr>
<td>dead_tuple_percent</td>
<td>float8</td>
<td>Percentage of dead tuples</td>
</tr>
<tr>
<td>approx_free_space</td>
<td>bigint</td>
<td>Total free space in bytes (estimated)</td>
</tr>
<tr>
<td>approx_free_percent</td>
<td>float8</td>
<td>Percentage of free space</td>
</tr>
</tbody>
</table>

The output columns are described in Table F.76.

Whereas `pgstattuple` always performs a full-table scan and returns an exact count of live and dead tuples (and their sizes) and free space, `pgstattuple_approx` tries to avoid the full-table scan and returns exact dead tuple statistics along with an approximation of the number and size of live tuples and free space.

It does this by skipping pages that have only visible tuples according to the visibility map (if a page has the corresponding VM bit set, then it is assumed to contain no dead tuples). For such pages, it derives the free space value from the free space map, and assumes that the rest of the space on the page is taken up by live tuples.

For pages that cannot be skipped, it scans each tuple, recording its presence and size in the appropriate counters, and adding up the free space on the page. At the end, it estimates the total number of live tuples based on the number of pages and tuples scanned (in the same way that VACUUM estimates `pg_class.reltuples`).

Table F.76. pgstattuple_approx Output Columns

F.43.2. Authors

Tatsuo Ishii, Satoshi Nagayasu and Abhijit Menon-Sen

F.44. pg_surgery
The `pg_surgery` module provides various functions to perform surgery on a damaged relation. These functions are unsafe by design and using them may corrupt (or further corrupt) your database. For example, these functions can easily be used to make a table inconsistent with its own indexes, to cause `UNIQUE` or `FOREIGN KEY` constraint violations, or even to make tuples visible which, when read, will cause a database server crash. They should be used with great caution and only as a last resort.

**F.44.1. Functions**

`heap_force_kill(regclass, tid[])` returns void

`heap_force_kill` marks "used" line pointers as "dead" without examining the tuples. The intended use of this function is to forcibly remove tuples that are not otherwise accessible. For example:

```sql
test=> select * from t1 where ctid = '(0, 1)';
ERROR:  could not access status of transaction 4007513275
DETAIL:  Could not open file "pg_xact/0EED": No such file or directory.
```

```sql
test=# select heap_force_kill('t1'::regclass, ARRAY['(0, 1)']::tid[]);
  heap_force_kill
-----------------
   (1 row)

test=# select * from t1 where ctid = '(0, 1)';
   (0 rows)
```

`heap_force_freeze(regclass, tid[])` returns void

`heap_force_freeze` marks tuples as frozen without examining the tuple data. The intended use of this function is to make accessible tuples which are inaccessible due to corrupted visibility information, or which prevent the table from being successfully vacuumed due to corrupted visibility information. For example:

```sql
test=> vacuum t1;
ERROR:  found xmin 507 from before relfrozenxid 515
CONTEXT:  while scanning block 0 of relation "public.t1"
```

```sql
test=# select ctid from t1 where xmin = 507;
  ctid
-------
   (0,3)
   (1 row)

test=# select heap_force_freeze('t1'::regclass, ARRAY['(0, 3)']::tid[]);
  heap_force_freeze
-------------------
   (1 row)

test=# select ctid from t1 where xmin = 2;
  ctid
-------
   (0,3)
   (1 row)
```

Additional Supplied Modules

F.45. pg_trgm

The pg_trgm module provides functions and operators for determining the similarity of alphanumeric text based on trigram matching, as well as index operator classes that support fast searching for similar strings.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.45.1. Trigram (or Trigraph) Concepts

A trigram is a group of three consecutive characters taken from a string. We can measure the similarity of two strings by counting the number of trigrams they share. This simple idea turns out to be very effective for measuring the similarity of words in many natural languages.

Note

.pg_trgm ignores non-word characters (non-alphanumerics) when extracting trigrams from a string. Each word is considered to have two spaces prefixed and one space suffixed when determining the set of trigrams contained in the string. For example, the set of trigrams in the string “cat” is “c”, “ca”, “cat”, and “at “. The set of trigrams in the string “foo|bar” is “f”, “fo”, “foo”, “oo “, “b”, “ba”, “bar”, and “ar “.

F.45.2. Functions and Operators

The functions provided by the pg_trgm module are shown in Table F.77, the operators in Table F.78.

Table F.77. pg_trgm Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>similarity (text, text) → real</td>
<td>Returns a number that indicates how similar the two arguments are. The range of the result is zero (indicating that the two strings are completely dissimilar) to one (indicating that the two strings are identical).</td>
</tr>
<tr>
<td>show_trgm (text) → text[]</td>
<td>Returns an array of all the trigrams in the given string. (In practice this is seldom useful except for debugging.)</td>
</tr>
<tr>
<td>word_similarity (text, text) → real</td>
<td>Returns a number that indicates the greatest similarity between the set of trigrams in the first string and any continuous extent of an ordered set of trigrams in the second string. For details, see the explanation below.</td>
</tr>
<tr>
<td>strict_word_similarity (text, text) → real</td>
<td>Same as word_similarity, but forces extent boundaries to match word boundaries. Since we don’t have cross-word trigrams, this function actually returns greatest similarity between first string and any continuous extent of words of the second string.</td>
</tr>
<tr>
<td>show_limit () → real</td>
<td>Returns the current similarity threshold used by the % operator. This sets the minimum similarity between two words for them to be considered similar enough to be misspellings of each other, for example. (Deprecated; instead use SHOW pg_trgm.similarity_threshold .)</td>
</tr>
<tr>
<td>set_limit (real) → real</td>
<td>Sets the current similarity threshold that is used by the % operator. The threshold must be between 0 and 1 (default is 0.3). Returns the same value passed in. (Deprecated; instead use SET pg_trgm.similarity_threshold .)</td>
</tr>
</tbody>
</table>
Consider the following example:

```sql
# SELECT word_similarity('word', 'two words');
word_similarity
-----------------
0.8
(1 row)
```

In the first string, the set of trigrams is `{ "w", "wo", "wor", "ord", "rd " }`. In the second string, the ordered set of trigrams is `{ "t", "tw", "two", "wo ", " w", " wo", "wor", "ord", "rds", "ds "}`. The most similar extent of an ordered set of trigrams in the second string is `{ "w", "wo", "wor", "ord" }`, and the similarity is 0.8.

This function returns a value that can be approximately understood as the greatest similarity between the first string and any substring of the second string. However, this function does not add padding to the boundaries of the extent. Thus, the number of additional characters present in the second string is not considered, except for the mismatched word boundaries.

At the same time, `strict_word_similarity` selects an extent of words in the second string. In the example above, `strict_word_similarity` would select the extent of a single word 'words', whose set of trigrams is `{ "w", "wo", "wor", "ord", "rds", "ds " }.

```sql
# SELECT strict_word_similarity('word', 'two words'), similarity('word', 'words');
strict_word_similarity | similarity
------------------------+------------
0.571429 |   0.571429
(1 row)
```

Thus, the `strict_word_similarity` function is useful for finding the similarity to whole words, while `word_similarity` is more suitable for finding the similarity for parts of words.

### Table F.78. `pg_trgm` Operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>text % text</code> → <code>boolean</code></td>
<td>Returns <code>true</code> if its arguments have a similarity that is greater than the current similarity threshold set by <code>pg_trgm.similarity_threshold</code> .</td>
</tr>
<tr>
<td><code>text &lt;\% text</code> → <code>boolean</code></td>
<td>Returns <code>true</code> if the similarity between the trigram set in the first argument and a continuous extent of an ordered trigram set in the second argument is greater than the current word similarity threshold set by <code>pg_trgm.word_similarity_threshold</code> parameter.</td>
</tr>
<tr>
<td><code>text %&gt;</code> <code>text</code> → <code>boolean</code></td>
<td>Commutator of the <code>&lt;\%</code> operator.</td>
</tr>
<tr>
<td><code>text &lt;\&lt; text</code> → <code>boolean</code></td>
<td>Returns <code>true</code> if its second argument has a continuous extent of an ordered trigram set that matches word boundaries, and its similarity to the trigram set of the first argument is greater than the current strict word similarity threshold set by the <code>pg_trgm.strict_word_similarity_threshold</code> parameter.</td>
</tr>
<tr>
<td><code>text %&gt;&gt; text</code> → <code>boolean</code></td>
<td>Commutator of the <code>&lt;\&lt;</code> operator.</td>
</tr>
<tr>
<td><code>text &lt;-&gt; text</code> → <code>real</code></td>
<td>Returns the “distance” between the arguments, that is one minus the <code>similarity()</code> value.</td>
</tr>
<tr>
<td><code>text &lt;\&lt;&lt; text</code> → <code>real</code></td>
<td>Returns the “distance” between the arguments, that is one minus the <code>word_similarity()</code> value.</td>
</tr>
</tbody>
</table>
### Additional Supplied Modules

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>text &lt;-&gt; text → real</td>
<td>Commutator of the &lt;-&gt; operator.</td>
</tr>
<tr>
<td>text &lt;&lt;&lt; text → real</td>
<td>Returns the “distance” between the arguments, that is one minus the strict_word_similarity() value.</td>
</tr>
<tr>
<td>text &lt;-&gt;&gt;&gt; text → real</td>
<td>Commutator of the &lt;&lt;&lt; operator.</td>
</tr>
</tbody>
</table>

#### F.45.3. GUC Parameters

- **pg_trgm.similarity_threshold(real)**
  
  Sets the current similarity threshold that is used by the % operator. The threshold must be between 0 and 1 (default is 0.3).

- **pg_trgm.word_similarity_threshold(real)**
  
  Sets the current word similarity threshold that is used by the < and > operators. The threshold must be between 0 and 1 (default is 0.6).

- **pg_trgm.strict_word_similarity_threshold(real)**
  
  Sets the current strict word similarity threshold that is used by the << and >>> operators. The threshold must be between 0 and 1 (default is 0.5).

#### F.45.4. Index Support

The pg_trgm module provides GiST and GIN index operator classes that allow you to create an index over a text column for the purpose of very fast similarity searches. These index types support the above-described similarity operators, and additionally support trigram-based index searches for LIKE, ILIKE, ~, ~* and = queries. Inequality operators are not supported. Note that those indexes may not be as efficient as regular B-tree indexes for equality operator.

Example:

```sql
CREATE TABLE test_trgm (t text);
CREATE INDEX trgm_idx ON test_trgm USING GIST (t gist_trgm_ops);
```

or

```sql
CREATE INDEX trgm_idx ON test_trgm USING GIN (t gin_trgm_ops);
```

gist_trgm_ops GiST opclass approximates a set of trigrams as a bitmap signature. Its optional integer parameter siglen determines the signature length in bytes. The default length is 12 bytes. Valid values of signature length are between 1 and 2024 bytes. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

Example of creating such an index with a signature length of 32 bytes:

```sql
CREATE INDEX trgm_idx ON test_trgm USING GIST (t gist_trgm_ops(siglen=32));
```

At this point, you will have an index on the t column that you can use for similarity searching. A typical query is

```sql
SELECT t, similarity(t, 'word') AS sml
FROM test_trgm
WHERE t % 'word'
ORDER BY sml DESC, t;
```
This will return all values in the text column that are sufficiently similar to \textit{word}, sorted from best match to worst. The index will be used to make this a fast operation even over very large data sets.

A variant of the above query is

\begin{verbatim}
SELECT t, t <-> 'word' AS dist
   FROM test_trgm
ORDER BY dist LIMIT 10;
\end{verbatim}

This can be implemented quite efficiently by GiST indexes, but not by GIN indexes. It will usually beat the first formulation when only a small number of the closest matches is wanted.

Also you can use an index on the \textit{t} column for word similarity or strict word similarity. Typical queries are:

\begin{verbatim}
SELECT t, word_similarity('word', t) AS sml
   FROM test_trgm
WHERE 'word' <% t
ORDER BY sml DESC, t;
\end{verbatim}

and

\begin{verbatim}
SELECT t, strict_word_similarity('word', t) AS sml
   FROM test_trgm
WHERE 'word' <<% t
ORDER BY sml DESC, t;
\end{verbatim}

This will return all values in the text column for which there is a continuous extent in the corresponding ordered trigram set that is sufficiently similar to the trigram set of \textit{word}, sorted from best match to worst. The index will be used to make this a fast operation even over very large data sets.

Possible variants of the above queries are:

\begin{verbatim}
SELECT t, 'word' <<<-> t AS dist
   FROM test_trgm
ORDER BY dist LIMIT 10;
\end{verbatim}

and

\begin{verbatim}
SELECT t, 'word' <<<-> t AS dist
   FROM test_trgm
ORDER BY dist LIMIT 10;
\end{verbatim}

This can be implemented quite efficiently by GiST indexes, but not by GIN indexes.

Beginning in PostgreSQL 9.1, these index types also support index searches for \texttt{LIKE} and \texttt{ILIKE}, for example

\begin{verbatim}
SELECT * FROM test_trgm WHERE t LIKE '%foo%bar';
\end{verbatim}

The index search works by extracting trigrams from the search string and then looking these up in the index. The more trigrams in the search string, the more effective the index search is. Unlike B-tree based searches, the search string need not be left-anchored.

Beginning in PostgreSQL 9.3, these index types also support index searches for regular-expression matches (~ and ~* operators), for example

\begin{verbatim}
SELECT * FROM test_trgm WHERE t ~ '(foo|bar)';
\end{verbatim}

The index search works by extracting trigrams from the regular expression and then looking these up in the index. The more trigrams that can be extracted from the regular expression, the more effective the index search is. Unlike B-tree based searches, the search string need not be left-anchored.

For both \texttt{LIKE} and regular-expression searches, keep in mind that a pattern with no extractable trigrams will degenerate to a full-index scan.
The choice between GiST and GIN indexing depends on the relative performance characteristics of GiST and GIN, which are discussed elsewhere.

F.45.5. Text Search Integration

Trigram matching is a very useful tool when used in conjunction with a full text index. In particular it can help to recognize misspelled input words that will not be matched directly by the full text search mechanism.

The first step is to generate an auxiliary table containing all the unique words in the documents:

```
CREATE TABLE words AS SELECT word FROM ts_stat('SELECT to_tsvector(''simple'', bodytext) FROM documents');
```

where documents is a table that has a text field bodytext that we wish to search. The reason for using the simple configuration with the to_tsvector function, instead of using a language-specific configuration, is that we want a list of the original (unstemmed) words.

Next, create a trigram index on the word column:

```
CREATE INDEX words_idx ON words USING GIN (word gin_trgm_ops);
```

Now, a SELECT query similar to the previous example can be used to suggest spellings for misspelled words in user search terms. A useful extra test is to require that the selected words are also of similar length to the misspelled word.

**Note**

Since the words table has been generated as a separate, static table, it will need to be periodically regenerated so that it remains reasonably up-to-date with the document collection. Keeping it exactly current is usually unnecessary.

This module is sponsored by Delta-Soft Ltd., Moscow, Russia.

F.46. pg_tsparser

`pg_tsparser` is a Postgres Pro extension for text search. This extension modifies the default text parsing strategy for words that include:

- underscores
- numbers and letters separated by the hyphen character

In addition to separate word parts returned by default, `pg_tsparser` also returns the whole word.
F.46.1. Installation and Setup

pg_tsparser is included into the Postgres Pro distribution. To enable pg_tsparser, once Postgres Pro is installed, create the pg_tsparser extension for each database you are planning to use:

CREATE EXTENSION pg_tsparser;

Once pg_tsparser is enabled, you can create your own text search configuration. In addition to pg_tsparser, you can use any available dictionary.

For example, you can create english_ts configuration for the English language, as follows:

CREATE TEXT SEARCH CONFIGURATION english_ts (PARSER = tsparser);

COMMENT ON TEXT SEARCH CONFIGURATION english_ts IS 'text search configuration for english language';

ALTER TEXT SEARCH CONFIGURATION english_ts
  ADD MAPPING FOR email, file, float, host, hword_numpart, int, numhword, numword, sfloat, uint, url, url_path, version
  WITH simple;

ALTER TEXT SEARCH CONFIGURATION english_ts
  ADD MAPPING FOR asciiword, asciihword, hword_asciipart, word, hword, hword_part
  WITH english_stem;

F.46.2. Examples

The following examples illustrate the difference in search results returned by pg_tsparser and the default parser:

```sql
SELECT to_tsvector('english', 'pg_trgm') as def_parser,
       to_tsvector('english_ts', 'pg_trgm') as new_parser;

<table>
<thead>
<tr>
<th>def_parser</th>
<th>new_parser</th>
</tr>
</thead>
<tbody>
<tr>
<td>'pg':1 'trgm':2</td>
<td>'pg':2 'pg_trgm':1 'trgm':3</td>
</tr>
</tbody>
</table>

(1 row)

SELECT to_tsvector('english', '123-abc') as def_parser,
       to_tsvector('english_ts', '123-abc') as new_parser;

<table>
<thead>
<tr>
<th>def_parser</th>
<th>new_parser</th>
</tr>
</thead>
<tbody>
<tr>
<td>'123':1 'abc':2</td>
<td>'123':2 '123-abc':1 'abc':3</td>
</tr>
</tbody>
</table>

(1 row)

SELECT to_tsvector('english', 'rel-3.2-A') as def_parser,
       to_tsvector('english_ts', 'rel-3.2-A') as new_parser;

<table>
<thead>
<tr>
<th>def_parser</th>
<th>new_parser</th>
</tr>
</thead>
<tbody>
<tr>
<td>'-3.2':2 'rel':1</td>
<td>'3.2':3 'rel':2 'rel-3.2-a':1</td>
</tr>
</tbody>
</table>

(1 row)
```

Postgres Professional, Moscow, Russia

F.47. pg_variables

The pg_variables module provides functions for working with variables of various types. The created variables are only available in the current user session.

F.47.1. Installation

The pg_variables extension is included into Postgres Pro. Once you have Postgres Pro installed, you must execute the CREATE EXTENSION command to enable pg_variables, as follows:

CREATE EXTENSION pg_variables;

F.47.2. Usage

The pg_variables module provides several functions for creating, reading, and managing variables of scalar, record, and array types. See the following sections for function descriptions and syntax:

- Section F.47.3.1 describes functions for scalar variables.
- Section F.47.3.2 describes functions for record variables.
- Section F.47.3.3 describes functions for array variables.
- Section F.47.3.4 lists functions you can use to manage all variables in your current session.

For detailed usage examples, see Section F.47.4.

F.47.2.1. Using Transactional Variables

By default, the created variables are non-transactional. Once successfully set, a variable exists for the whole session, regardless of rollbacks, if any. For example:

```
SELECT pgv_set('vars', 'int1', 101);
BEGIN;
SELECT pgv_set('vars', 'int2', 102);
ROLLBACK;
```

```
SELECT * FROM pgv_list() order by package, name;
```

<table>
<thead>
<tr>
<th>package</th>
<th>name</th>
<th>is_transactional</th>
</tr>
</thead>
<tbody>
<tr>
<td>vars</td>
<td>int1</td>
<td>f</td>
</tr>
<tr>
<td>vars</td>
<td>int2</td>
<td>f</td>
</tr>
</tbody>
</table>

If you would like to use variables that support transactions and savepoints, pass the optional is_transactional flag as the last parameter when creating this variable:

```
BEGIN;
SELECT pgv_set('vars', 'trans_int', 101, true);
SAVEPOINT sp1;
SELECT pgv_set('vars', 'trans_int', 102, true);
ROLLBACK TO sp1;
COMMIT;
SELECT pgv_get('vars', 'trans_int', NULL::int);
```

```
pgv_get
--------
101
```

You must use the is_transactional flag every time you change the value of a transactional variable using pgv_set() or pgv_insert() functions. Otherwise, an error occurs. Other functions do not require this flag.
Additional Supplied Modules

SELECT pgv_insert('pack', 'var_record', row(123::int, 'text'::text), true);

SELECT pgv_insert('pack', 'var_record', row(456::int, 'another text'::text));
ERROR: variable "var_record" already created as TRANSACTIONAL

SELECT pgv_delete('pack', 'var_record', 123::int);

If the pgv_free() or pgv_remove() function calls are rolled back, the affected transactional variables will be restored, unlike non-transactional variables, which are removed permanently. For example:

SELECT pgv_set('pack', 'var_reg', 123);
SELECT pgv_set('pack', 'var_trans', 456, true);
BEGIN;
SELECT pgv_free();
ROLLBACK;
SELECT * FROM pgv_list();
 package |   name    | is_transactional
---------+-----------+------------------
 pack    | var_trans | t

F.47.3. Functions

F.47.3.1. Scalar Variables

The following functions support scalar variables:

<table>
<thead>
<tr>
<th>Function</th>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>pgv_set(package text, name text, value anynonarray, is_transactional bool default false)</td>
<td>void</td>
</tr>
<tr>
<td>pgv_get(package text, name text, var_ type anynonarray, strict bool default true)</td>
<td>anynonarray</td>
</tr>
</tbody>
</table>

To use the pgv_get() function, you must first create a package and a variable using the pgv_set() function. If the specified package or variable does not exist, an error occurs:

SELECT pgv_get('vars', 'int1', NULL::int);
ERROR: unrecognized package "vars"

SELECT pgv_get('vars', 'int1', NULL::int);
ERROR: unrecognized variable "int1"

pgv_get() function checks the variable type. If the specified type does not match the type of the variable, an error is raised:

SELECT pgv_get('vars', 'int1', NULL::text);
ERROR: variable "int1" requires "integer" value

F.47.3.2. Records

The following functions support collections of record variables:

<table>
<thead>
<tr>
<th>Function</th>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pgv_insert(package text, name text, r record, is_transactional bool default false)</td>
<td>void</td>
<td>Inserts a record into a variable collection for the specified package. If the package or variable does not exist, it is</td>
</tr>
</tbody>
</table>
Additional Supplied Modules

<table>
<thead>
<tr>
<th>Function</th>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pgv_update(package text, name text, r record)</td>
<td>boolean</td>
<td>Updates a record with the corresponding primary key (the first column of r is the primary key). Returns true if the record was found. If this variable collection has another structure, an error is raised.</td>
</tr>
<tr>
<td>pgv_delete(package text, name text, value anyonarray)</td>
<td>boolean</td>
<td>Deletes a record with the corresponding primary key (the first column of r is the primary key). Returns true if the record was found.</td>
</tr>
<tr>
<td>pgv_select(package text, name text)</td>
<td>set of records</td>
<td>Returns the variable collection records.</td>
</tr>
<tr>
<td>pgv_select(package text, name text, value anyonarray)</td>
<td>record</td>
<td>Returns the record with the corresponding primary key (the first column of r is a primary key).</td>
</tr>
<tr>
<td>pgv_select(package text, name text, value anyarray)</td>
<td>set of records</td>
<td>Returns the variable collection records with the corresponding primary keys (the first column of r is a primary key).</td>
</tr>
</tbody>
</table>

To use `pgv_update()`, `pgv_delete()` and `pgv_select()` functions, you must first create a package and a variable using the `pgv_insert()` function. The variable type and the record type must be the same; otherwise, an error occurs.

### F.47.3.3. Arrays

The following functions support array variables:

<table>
<thead>
<tr>
<th>Function</th>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>pgv_set(package text, name text, value anyarray, is_transactional bool default false)</td>
<td>void</td>
</tr>
<tr>
<td>pgv_get(package text, name text, var_type anyarray, strict bool default true)</td>
<td>anyarray</td>
</tr>
</tbody>
</table>

Usage instructions for these functions are the same as those provided in Section F.47.3.1 for scalar variables.

### F.47.3.4. Miscellaneous Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pgv_exists(package text, name text)</td>
<td>bool</td>
<td>Returns true if the specified package and variable exist.</td>
</tr>
</tbody>
</table>
Additional Supplied Modules

<table>
<thead>
<tr>
<th>Function</th>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>pgv_exists(package text)</code></td>
<td>bool</td>
<td>Returns true if the specified package exists.</td>
</tr>
<tr>
<td><code>pgv_remove(package text, name text)</code></td>
<td>void</td>
<td>Removes the variable with the specified name. The specified package and variable must exist; otherwise, an error is raised.</td>
</tr>
<tr>
<td><code>pgv_remove(package text)</code></td>
<td>void</td>
<td>Removes the specified package and all the corresponding variables. The specified package must exist; otherwise, an error is raised.</td>
</tr>
<tr>
<td><code>pgv_free()</code></td>
<td>void</td>
<td>Removes all packages and variables.</td>
</tr>
<tr>
<td><code>pgv_list()</code></td>
<td>table</td>
<td>Displays all the available variables and the corresponding packages, as well as whether each variable is transactional.</td>
</tr>
<tr>
<td><code>pgv_stats()</code></td>
<td>table</td>
<td>Returns the list of assigned packages and the amount of memory used by variables, in bytes. If you are using transactional variables, this list also includes all deleted packages that still may be restored by a ROLLBACK. This function only supports Postgres Pro 9.6 or higher.</td>
</tr>
</tbody>
</table>

F.47.3.5. Deprecated Functions

F.47.3.5.1. Integer Variables

The following functions are deprecated. Use generic functions for *scalar variables* instead.

<table>
<thead>
<tr>
<th>Function</th>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>pgv_set_int(package text, name text, value int, is_transactional bool default false)</code></td>
<td>void</td>
</tr>
<tr>
<td><code>pgv_get_int(package text, name text, strict bool default true)</code></td>
<td>int</td>
</tr>
</tbody>
</table>

F.47.3.5.2. Text Variables

The following functions are deprecated. Use generic functions for *scalar variables* instead.

<table>
<thead>
<tr>
<th>Function</th>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>pgv_set_text(package text, name text, value text, is_transactional bool default false)</code></td>
<td>void</td>
</tr>
<tr>
<td><code>pgv_get_text(package text, name text, strict bool default true)</code></td>
<td>text</td>
</tr>
</tbody>
</table>

F.47.3.5.3. Numeric Variables

The following functions are deprecated. Use generic functions for *scalar variables* instead.
### Additional Supplied Modules

<table>
<thead>
<tr>
<th>Function</th>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>pgv_set_numeric</code></td>
<td><code>void</code></td>
</tr>
<tr>
<td><code>pgv_set_numeric(package text, name text, value numeric, is_transactional bool default false)</code></td>
<td></td>
</tr>
<tr>
<td><code>pgv_set_numeric(package text, name text, strict bool default true)</code></td>
<td><code>numeric</code></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>

<tr>
<td><code>pgv_get_date(package text, name text, strict bool default true)</code></td>
<td><code>date</code></td>
</tr>
</tbody>
</table>

#### F.47.3.5.7. Jsonb Variables

The following functions are deprecated. Use generic functions for scalar variables instead.

<table>
<thead>
<tr>
<th>Function</th>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>pgv_set_jsonb</code></td>
<td><code>void</code></td>
</tr>
<tr>
<td><code>pgv_set_jsonb(package text, name text, value jsonb, is_transactional bool default false)</code></td>
<td></td>
</tr>
<tr>
<td><code>pgv_set_jsonb(package text, name text, strict bool default true)</code></td>
<td><code>jsonb</code></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Function</th>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>pgv_get_jsonb</code></td>
<td><code>void</code></td>
</tr>
<tr>
<td><code>pgv_get_jsonb(package text, name text, strict bool default true)</code></td>
<td><code>jsonb</code></td>
</tr>
</tbody>
</table>

#### F.47.4. Examples

Define scalar variables using the `pgv_set()` function, and then return their values using the `pgv_get()` function:
SELECT pgv_set('vars', 'int1', 101);
SELECT pgv_set('vars', 'int2', 102);
SELECT pgv_set('vars', 'text1', 'text variable'::text);

SELECT pgv_get('vars', 'int1', NULL::int);
pgv_get
--------------
 101

SELECT pgv_get('vars', 'int2', NULL::int);
pgv_get
--------------
 102

SELECT pgv_get('vars', 'text1', NULL::text);
pgv_get
---------------
text variable

Let's assume we have the tab table and examine several examples of using record variables:

CREATE TABLE tab (id int, t varchar);
INSERT INTO tab VALUES (0, 'str00'), (1, 'str11');

You can use the following functions to work with record variables:

SELECT pgv_insert('vars', 'r1', tab) FROM tab;

SELECT pgv_select('vars', 'r1');
pgv_select
------------
(1,str11)
(0,str00)

SELECT pgv_select('vars', 'r1', 1);
pgv_select
------------
(1,str11)

SELECT pgv_select('vars', 'r1', 0);
pgv_select
------------
(0,str00)

SELECT pgv_select('vars', 'r1', ARRAY[1, 0]);
pgv_select
------------
(1,str11)
(0,str00)

SELECT pgv_delete('vars', 'r1', 1);

Consider the behavior of a transactional variable var_text when changed before and after savepoints:

SELECT pgv_set('pack', 'var_text', 'before transaction block'::text, true);
BEGIN;
SELECT pgv_set('pack', 'var_text', 'before savepoint'::text, true);
SAVEPOINT sp1;
SELECT pgv_set('pack', 'var_text', 'savepoint sp1'::text, true);
SAVEPOINT sp2;
SELECT pgv_set('pack', 'var_text', 'savepoint sp2'::text, true);
RELEASE sp2;
SELECT pgv_get('pack', 'var_text', NULL::text);
  pgv_get
--------------
  savepoint sp2
ROLLBACK TO sp1;
SELECT pgv_get('pack', 'var_text', NULL::text);
  pgv_get
--------------
  before savepoint
ROLLBACK;
SELECT pgv_get('pack', 'var_text', NULL::text);
  pgv_get
-------------------
  before transaction block

If you create a variable after BEGIN or SAVEPOINT statements and than rollback to the previous state, the transactional variable is removed:

BEGIN;
SAVEPOINT sp1;
SAVEPOINT sp2;
SELECT pgv_set('pack', 'var_int', 122, true);
RELEASE SAVEPOINT sp2;
SELECT pgv_get('pack', 'var_int', NULL::int);
  pgv_get
-------
  122
ROLLBACK TO sp1;
SELECT pgv_get('pack', 'var_int', NULL::int);
ERROR: unrecognized variable "var_int"
COMMIT;

List the available packages and variables:

```
SELECT * FROM pgv_list() ORDER BY package, name;
  package |   name   | is_transactional
-----------+----------+------------------
   pack    | var_text | t
   vars    | int1     | f
   vars    | int2     | f
   vars    | r1       | f
   vars    | text1    | f
```

Get the amount of memory used by variables, in bytes:

```
SELECT * FROM pgv_stats() ORDER BY package;
  package | allocated_memory
-----------+------------------
   pack    |            16384
   vars    |            32768
```

2459
Delete the specified variables or packages:

SELECT pgv_remove('vars', 'int1');
SELECT pgv_remove('vars');

Delete all packages and variables:

SELECT pgv_free();

Postgres Professional, Moscow, Russia

F.48. pg_visibility

The pg_visibility module provides a means for examining the visibility map (VM) and page-level visibility information of a table. It also provides functions to check the integrity of a visibility map and to force it to be rebuilt.

Three different bits are used to store information about page-level visibility. The all-visible bit in the visibility map indicates that every tuple in the corresponding page of the relation is visible to every current and future transaction. The all-frozen bit in the visibility map indicates that every tuple in the page is frozen; that is, no future vacuum will need to modify the page until such time as a tuple is inserted, updated, deleted, or locked on that page. The page header's PD_ALL_VISIBLE bit has the same meaning as the all-visible bit in the visibility map, but is stored within the data page itself rather than in a separate data structure. These two bits will normally agree, but the page's all-visible bit can sometimes be set while the visibility map bit is clear after a crash recovery. The reported values can also disagree because of a change that occurs after pg_visibility examines the visibility map and before it examines the data page. Any event that causes data corruption can also cause these bits to disagree.

Functions that display information about PD_ALL_VISIBLE bits are much more costly than those that only consult the visibility map, because they must read the relation's data blocks rather than only the (much smaller) visibility map. Functions that check the relation's data blocks are similarly expensive.

F.48.1. Functions

pg_visibility_map(relation regclass, blkno bigint, all_visible OUT boolean, all_frozen OUT boolean) returns record

Returns the all-visible and all-frozen bits in the visibility map for the given block of the given relation.

pg_visibility(relation regclass, blkno bigint, all_visible OUT boolean, all_frozen OUT boolean, pd_all_visible OUT boolean) returns record

Returns the all-visible and all-frozen bits in the visibility map for the given block of the given relation, plus the PD_ALL_VISIBLE bit of that block.

pg_visibility_map(relation regclass, blkno OUT bigint, all_visible OUT boolean, all_frozen OUT boolean) returns setof record

Returns the all-visible and all-frozen bits in the visibility map for each block of the given relation.

pg_visibility(relation regclass, blkno OUT bigint, all_visible OUT boolean, all_frozen OUT boolean, pd_all_visible OUT boolean) returns setof record

Returns the all-visible and all-frozen bits in the visibility map for each block of the given relation, plus the PD_ALL_VISIBLE bit of each block.

pg_visibility_map_summary(relation regclass, all_visible OUT bigint, all_frozen OUT bigint) returns record

Returns the number of all-visible pages and the number of all-frozen pages in the relation according to the visibility map.
pg_check_frozen(relation regclass, t_ctid OUT tid) returns setof tid

Returns the TIDs of non-frozen tuples stored in pages marked all-frozen in the visibility map. If this function returns a non-empty set of TIDs, the visibility map is corrupt.

pg_check_visible(relation regclass, t_ctid OUT tid) returns setof tid

Returns the TIDs of non-all-visible tuples stored in pages marked all-visible in the visibility map. If this function returns a non-empty set of TIDs, the visibility map is corrupt.

pg_truncate_visibility_map(relation regclass) returns void

Truncates the visibility map for the given relation. This function is useful if you believe that the visibility map for the relation is corrupt and wish to force rebuilding it. The first VACUUM executed on the given relation after this function is executed will scan every page in the relation and rebuild the visibility map. (Until that is done, queries will treat the visibility map as containing all zeroes.)

By default, these functions are executable only by superusers and members of the pg_stat_scan_tables role, with the exception of pg_truncate_visibility_map(relation regclass) which can only be executed by superusers.

Robert Haas <rhaas@postgresql.org>

F.49. plantuner

The plantuner module provides hints for the planner that can disable or enable indexes for query execution.

F.49.1. Motivation

In some cases, it may be required to control the planner by providing hints that make the optimizer ignore some parts of its algorithm. There are many situations when a developer may want to temporarily disable specific index(es), without dropping them, or to instruct the planner to use a specific index.

This version of plantuner provides a possibility to hide the specified indexes from Postgres Pro planner, so it will not use them. For some workloads, Postgres Pro could be too pessimistic about newly created tables and assume that there are much more rows in a table than it actually has. If the plantuner.fix_empty_table GUC variable is set to true, plantuner sets to zero the number of pages/tuples of the table that has no blocks in a file.

F.49.2. GUC Variables

plantuner.disable_index — list of indexes invisible to planner.

plantuner.enable_index — list of indexes visible to planner even if they are hidden by plantuner.disable_index.

F.49.3. Example

To enable the module, you can either load plantuner shared library in a psql session or specify shared_preload_libraries option in postgresql.conf.

=## LOAD 'plantuner';
=## create table test(id int);
=## create index id_idx on test(id);
=## create index id_idx2 on test(id);
=## \d test
    Table "public.test"
    Column | Type | Modifiers
### Additional Supplied Modules

| id     | integer |
|--------+---------+-----------|
| "id_idx" btree (id) |
| "id_idx2" btree (id) |

```sql
=# explain select id from test where id=1;

QUERY PLAN

Bitmap Heap Scan on test  (cost=4.34..15.03 rows=12 width=4)
  Recheck Cond: (id = 1)
  ->  Bitmap Index Scan on id_idx2  (cost=0.00..4.34 rows=12 width=0)
       Index Cond: (id = 1)
(4 rows)
```

```sql
=# set enable_seqscan=off;
=# set plantuner.disable_index='id_idx2';
=# explain select id from test where id=1;

QUERY PLAN

Bitmap Heap Scan on test  (cost=4.34..15.03 rows=12 width=4)
  Recheck Cond: (id = 1)
  ->  Bitmap Index Scan on id_idx  (cost=0.00..4.34 rows=12 width=0)
       Index Cond: (id = 1)
(4 rows)
```

```sql
=# set plantuner.disable_index='id_idx2,id_idx';
=# explain select id from test where id=1;

QUERY PLAN

Seq Scan on test  (cost=10000000000.00..10000000040.00 rows=12 width=4)
  Filter: (id = 1)
(2 rows)
```

```sql
=# set plantuner.enable_index='id_idx';
=# explain select id from test where id=1;

QUERY PLAN

Bitmap Heap Scan on test  (cost=4.34..15.03 rows=12 width=4)
  Recheck Cond: (id = 1)
  ->  Bitmap Index Scan on id_idx  (cost=0.00..4.34 rows=12 width=0)
       Index Cond: (id = 1)
(4 rows)
```

### F.50. postgres_fdw

The `postgres_fdw` module provides the foreign-data wrapper `postgres_fdw`, which can be used to access data stored in external Postgres Pro servers.

The functionality provided by this module overlaps substantially with the functionality of the older `dblink` module. But `postgres_fdw` provides more transparent and standards-compliant syntax for accessing remote tables, and can give better performance in many cases.

To prepare for remote access using `postgres_fdw`:

1. Install the `postgres_fdw` extension using `CREATE EXTENSION`.
2. Create a foreign server object, using CREATE SERVER, to represent each remote database you want to connect to. Specify connection information, except user and password, as options of the server object.

3. Create a user mapping, using CREATE USER MAPPING, for each database user you want to allow to access each foreign server. Specify the remote user name and password to use as user and password options of the user mapping.

4. Create a foreign table, using CREATE FOREIGN TABLE or IMPORT FOREIGN SCHEMA, for each remote table you want to access. The columns of the foreign table must match the referenced remote table. You can, however, use table and/or column names different from the remote table’s, if you specify the correct remote names as options of the foreign table object.

Now you need only SELECT from a foreign table to access the data stored in its underlying remote table. You can also modify the remote table using INSERT, UPDATE, DELETE, or TRUNCATE. (Of course, the remote user you have specified in your user mapping must have privileges to do these things.)

Note that the ONLY option specified in SELECT, UPDATE, DELETE or TRUNCATE has no effect when accessing or modifying the remote table.

Note that postgres_fdw currently lacks support for INSERT statements with an ON CONFLICT DO UPDATE clause. However, the ON CONFLICT DO NOTHING clause is supported, provided a unique index inference specification is omitted. Note also that postgres_fdw supports row movement invoked by UPDATE statements executed on partitioned tables, but it currently does not handle the case where a remote partition chosen to insert a moved row into is also an UPDATE target partition that will be updated elsewhere in the same command.

It is generally recommended that the columns of a foreign table be declared with exactly the same data types, and collations if applicable, as the referenced columns of the remote table. Although postgres_fdw is currently rather forgiving about performing data type conversions at need, surprising semantic anomalies may arise when types or collations do not match, due to the remote server interpreting query conditions differently from the local server.

Note that a foreign table can be declared with fewer columns, or with a different column order, than its underlying remote table has. Matching of columns to the remote table is by name, not position.

**F.50.1. FDW Options of postgres_fdw**

**F.50.1.1. Connection Options**

A foreign server using the postgres_fdw foreign data wrapper can have the same options that libpq accepts in connection strings, as described in Section 32.1.2, except that these options are not allowed or have special handling:

- user, password and sslpassword (specify these in a user mapping, instead, or use a service file)
- client_encoding (this is automatically set from the local server encoding)
- fallback_application_name (always set to postgres_fdw)
- sslkey and sslcert - these may appear in either or both a connection and a user mapping. If both are present, the user mapping setting overrides the connection setting.

Only superusers may create or modify user mappings with the sslcert or sslkey settings.

Only superusers may connect to foreign servers without password authentication, so always specify the password option for user mappings belonging to non-superusers.

A superuser may override this check on a per-user-mapping basis by setting the user mapping option password_required 'false', e.g.,

```
ALTER USER MAPPING FOR some_non_superuser SERVER loopback_nopw
OPTIONS (ADD password_required 'false');
```

To prevent unprivileged users from exploiting the authentication rights of the unix user the postgres server is running as to escalate to superuser rights, only the superuser may set this option on a user mapping.
Care is required to ensure that this does not allow the mapped user the ability to connect as superuser to the mapped database per CVE-2007-3278 and CVE-2007-6601. Don't set `password_required=false` on the public role. Keep in mind that the mapped user can potentially use any client certificates, `.pgpass`, `.pg_service.conf` etc in the unix home directory of the system user the postgres server runs as. They can also use any trust relationship granted by authentication modes like peer or ident authentication.

F.50.1.2. Object Name Options

These options can be used to control the names used in SQL statements sent to the remote Postgres Pro server. These options are needed when a foreign table is created with names different from the underlying remote table's names.

`schema_name`

This option, which can be specified for a foreign table, gives the schema name to use for the foreign table on the remote server. If this option is omitted, the name of the foreign table's schema is used.

`table_name`

This option, which can be specified for a foreign table, gives the table name to use for the foreign table on the remote server. If this option is omitted, the foreign table's name is used.

`column_name`

This option, which can be specified for a column of a foreign table, gives the column name to use for the column on the remote server. If this option is omitted, the column's name is used.

F.50.1.3. Cost Estimation Options

`postgres_fdw` retrieves remote data by executing queries against remote servers, so ideally the estimated cost of scanning a foreign table should be whatever it costs to be done on the remote server, plus some overhead for communication. The most reliable way to get such an estimate is to ask the remote server and then add something for overhead — but for simple queries, it may not be worth the cost of an additional remote query to get a cost estimate. So `postgres_fdw` provides the following options to control how cost estimation is done:

`use_remote_estimate`

This option, which can be specified for a foreign table or a foreign server, controls whether `postgres_fdw` issues remote `EXPLAIN` commands to obtain cost estimates. A setting for a foreign table overrides any setting for its server, but only for that table. The default is `false`.

`fdw_startup_cost`

This option, which can be specified for a foreign server, is a floating point value that is added to the estimated startup cost of any foreign-table scan on that server. This represents the additional overhead of establishing a connection, parsing and planning the query on the remote side, etc. The default value is `100`.

`fdw_tuple_cost`

This option, which can be specified for a foreign server, is a floating point value that is used as extra cost per-tuple for foreign-table scans on that server. This represents the additional overhead of data transfer between servers. You might increase or decrease this number to reflect higher or lower network delay to the remote server. The default value is `0.01`.

When `use_remote_estimate` is `true`, `postgres_fdw` obtains row count and cost estimates from the remote server and then adds `fdw_startup_cost` and `fdw_tuple_cost` to the cost estimates. When `use_remote_estimate` is `false`, `postgres_fdw` performs local row count and cost estimation and then adds `fdw_startup_cost` and `fdw_tuple_cost` to the cost estimates. This local estimation is unlikely to be very accurate unless local copies of the remote table's statistics are available. Running `ANALYZE` on the foreign table is the way to update the local statistics; this will perform a scan of the remote table and then calculate and store statistics just as though the table were local. Keeping local statistics can
be a useful way to reduce per-query planning overhead for a remote table — but if the remote table is frequently updated, the local statistics will soon be obsolete.

F.50.1.4. Remote Execution Options

By default, only WHERE clauses using built-in operators and functions will be considered for execution on the remote server. Clauses involving non-built-in functions are checked locally after rows are fetched. If such functions are available on the remote server and can be relied on to produce the same results as they do locally, performance can be improved by sending such WHERE clauses for remote execution. This behavior can be controlled using the following option:

extensions

This option is a comma-separated list of names of Postgres Pro extensions that are installed, in compatible versions, on both the local and remote servers. Functions and operators that are immutable and belong to a listed extension will be considered shippable to the remote server. This option can only be specified for foreign servers, not per-table.

When using the extensions option, it is the user's responsibility that the listed extensions exist and behave identically on both the local and remote servers. Otherwise, remote queries may fail or behave unexpectedly.

fetch_size

This option specifies the number of rows postgres_fdw should get in each fetch operation. It can be specified for a foreign table or a foreign server. The option specified on a table overrides an option specified for the server. The default is 100.

batch_size

This option specifies the number of rows postgres_fdw should insert in each insert operation. It can be specified for a foreign table or a foreign server. The option specified on a table overrides an option specified for the server. The default is 1.

Note the actual number of rows postgres_fdw inserts at once depends on the number of columns and the provided batch_size value. The batch is executed as a single query, and the libpq protocol (which postgres_fdw uses to connect to a remote server) limits the number of parameters in a single query to 65535. When the number of columns * batch_size exceeds the limit, the batch_size will be adjusted to avoid an error.

F.50.1.5. Asynchronous Execution Options

postgres_fdw supports asynchronous execution, which runs multiple parts of an Append node concurrently rather than serially to improve performance. This execution can be controlled using the following option:

async_capable

This option controls whether postgres_fdw allows foreign tables to be scanned concurrently for asynchronous execution. It can be specified for a foreign table or a foreign server. A table-level option overrides a server-level option. The default is false.

In order to ensure that the data being returned from a foreign server is consistent, postgres_fdw will only open one connection for a given foreign server and will run all queries against that server sequentially even if there are multiple foreign tables involved, unless those tables are subject to different user mappings. In such a case, it may be more performant to disable this option to eliminate the overhead associated with running queries asynchronously.

Asynchronous execution is applied even when an Append node contains subplan(s) executed synchronously as well as subplan(s) executed asynchronously. In such a case, if the asynchronous subplans are ones processed using postgres_fdw, tuples from the asynchronous subplans are not returned until after at least one synchronous subplan returns all tuples, as that subplan is executed
while the asynchronous subplans are waiting for the results of asynchronous queries sent to foreign servers. This behavior might change in a future release.

F.50.1.6. **Updatability Options**

By default all foreign tables using `postgres_fdw` are assumed to be updatable. This may be overridden using the following option:

```plaintext
updatable
```

This option controls whether `postgres_fdw` allows foreign tables to be modified using `INSERT`, `UPDATE` and `DELETE` commands. It can be specified for a foreign table or a foreign server. A table-level option overrides a server-level option. The default is `true`.

Of course, if the remote table is not in fact updatable, an error would occur anyway. Use of this option primarily allows the error to be thrown locally without querying the remote server. Note however that the `information_schema` views will report a `postgres_fdw` foreign table to be updatable (or not) according to the setting of this option, without any check of the remote server.

F.50.1.7. **Truncatability Options**

By default all foreign tables using `postgres_fdw` are assumed to be truncatable. This may be overridden using the following option:

```plaintext
truncatable
```

This option controls whether `postgres_fdw` allows foreign tables to be truncated using the `TRUNCATE` command. It can be specified for a foreign table or a foreign server. A table-level option overrides a server-level option. The default is `true`.

Of course, if the remote table is not in fact truncatable, an error would occur anyway. Use of this option primarily allows the error to be thrown locally without querying the remote server.

F.50.1.8. **Importing Options**

`postgres_fdw` is able to import foreign table definitions using `IMPORT FOREIGN SCHEMA`. This command creates foreign table definitions on the local server that match tables or views present on the remote server. If the remote tables to be imported have columns of user-defined data types, the local server must have compatible types of the same names.

Importing behavior can be customized with the following options (given in the `IMPORT FOREIGN SCHEMA` command):

```plaintext
import_collate
```

This option controls whether column `COLLATE` options are included in the definitions of foreign tables imported from a foreign server. The default is `true`. You might need to turn this off if the remote server has a different set of collation names than the local server does, which is likely to be the case if it's running on a different operating system. If you do so, however, there is a very severe risk that the imported table columns' collations will not match the underlying data, resulting in anomalous query behavior.

Even when this parameter is set to `true`, importing columns whose collation is the remote server's default can be risky. They will be imported with `COLLATE "default"`, which will select the local server's default collation, which could be different.

```plaintext
import_default
```

This option controls whether column `DEFAULT` expressions are included in the definitions of foreign tables imported from a foreign server. The default is `false`. If you enable this option, be wary of defaults that might get computed differently on the local server than they would be on the remote server; `nextval()` is a common source of problems. The `IMPORT` will fail altogether if an imported default expression uses a function or operator that does not exist locally.
import_generated

This option controls whether column \texttt{GENERATED} expressions are included in the definitions of foreign tables imported from a foreign server. The default is \texttt{true}. The \texttt{IMPORT} will fail altogether if an imported generated expression uses a function or operator that does not exist locally.

import_not_null

This option controls whether column \texttt{NOT NULL} constraints are included in the definitions of foreign tables imported from a foreign server. The default is \texttt{true}.

Note that constraints other than \texttt{NOT NULL} will never be imported from the remote tables. Although Postgres Pro does support check constraints on foreign tables, there is no provision for importing them automatically, because of the risk that a constraint expression could evaluate differently on the local and remote servers. Any such inconsistency in the behavior of a check constraint could lead to hard-to-detect errors in query optimization. So if you wish to import check constraints, you must do so manually, and you should verify the semantics of each one carefully. For more detail about the treatment of check constraints on foreign tables, see \texttt{CREATE FOREIGN TABLE}.

Tables or foreign tables which are partitions of some other table are imported only when they are explicitly specified in \texttt{LIMIT TO} clause. Otherwise they are automatically excluded from \texttt{IMPORT FOREIGN SCHEMA}. Since all data can be accessed through the partitioned table which is the root of the partitioning hierarchy, importing only partitioned tables should allow access to all the data without creating extra objects.

F.50.1.9. Connection Management Options

By default, all connections that \texttt{postgres_fdw} establishes to foreign servers are kept open in the local session for re-use.

keep_connections

This option controls whether \texttt{postgres_fdw} keeps the connections to the foreign server open so that subsequent queries can re-use them. It can only be specified for a foreign server. The default is \texttt{on}. If set to \texttt{off}, all connections to this foreign server will be discarded at the end of each transaction.

F.50.2. Functions

\texttt{postgres_fdw_get_connections(OUT server_name text, OUT valid boolean) returns setof record}

This function returns the foreign server names of all the open connections that \texttt{postgres_fdw} established from the local session to the foreign servers. It also returns whether each connection is valid or not. \texttt{false} is returned if the foreign server connection is used in the current local transaction but its foreign server or user mapping is changed or dropped (Note that server name of an invalid connection will be \texttt{NULL} if the server is dropped), and then such invalid connection will be closed at the end of that transaction. \texttt{true} is returned otherwise. If there are no open connections, no record is returned. Example usage of the function:

\begin{verbatim}
postgres=# SELECT * FROM postgres_fdw_get_connections() ORDER BY 1;
 server_name | valid
-------------+-------
 loopback1   | t
 loopback2   | f
\end{verbatim}

\texttt{postgres_fdw_disconnect(server_name text) returns boolean}

This function discards the open connections that are established by \texttt{postgres_fdw} from the local session to the foreign server with the given name. Note that there can be multiple connections to the given server using different user mappings. If the connections are used in the current local transaction, they are not disconnected and warning messages are reported. This function returns \texttt{true} if it disconnects at least one connection, otherwise \texttt{false}. If no foreign server with the given name is found, an error is reported. Example usage of the function:
Additional Supplied Modules

postgres=# SELECT postgres_fdw_disconnect('loopback1');
postgres_fdw_disconnect
-------------------------
t

postgres_fdw_disconnect_all() returns boolean

This function discards all the open connections that are established by postgres_fdw from the local session to foreign servers. If the connections are used in the current local transaction, they are not disconnected and warning messages are reported. This function returns true if it disconnects at least one connection, otherwise false. Example usage of the function:

postgres=# SELECT postgres_fdw_disconnect_all();
postgres_fdw_disconnect_all
----------------------------
t

F.50.3. Connection Management

postgres_fdw establishes a connection to a foreign server during the first query that uses a foreign table associated with the foreign server. By default this connection is kept and re-used for subsequent queries in the same session. This behavior can be controlled using keep_connections option for a foreign server. If multiple user identities (user mappings) are used to access the foreign server, a connection is established for each user mapping.

When changing the definition of or removing a foreign server or a user mapping, the associated connections are closed. But note that if any connections are in use in the current local transaction, they are kept until the end of the transaction. Closed connections will be re-established when they are necessary by future queries using a foreign table.

Once a connection to a foreign server has been established, it's by default kept until the local or corresponding remote session exits. To disconnect a connection explicitly, keep_connections option for a foreign server may be disabled, or postgres_fdw_disconnect and postgres_fdw_disconnect_all functions may be used. For example, these are useful to close connections that are no longer necessary, thereby releasing connections on the foreign server.

F.50.4. Transaction Management

During a query that references any remote tables on a foreign server, postgres_fdw opens a transaction on the remote server if one is not already open corresponding to the current local transaction. The remote transaction is committed or aborted when the local transaction commits or aborts. Savepoints are similarly managed by creating corresponding remote savepoints.

The remote transaction uses SERIALIZABLE isolation level when the local transaction has SERIALIZABLE isolation level; otherwise it uses REPEATABLE READ isolation level. This choice ensures that if a query performs multiple table scans on the remote server, it will get snapshot-consistent results for all the scans. A consequence is that successive queries within a single transaction will see the same data from the remote server, even if concurrent updates are occurring on the remote server due to other activities. That behavior would be expected anyway if the local transaction uses SERIALIZABLE or REPEATABLE READ isolation level, but it might be surprising for a READ COMMITTED local transaction. A future Postgres Pro release might modify these rules.

Note that it is currently not supported by postgres_fdw to prepare the remote transaction for two-phase commit.

F.50.5. Remote Query Optimization

postgres_fdw attempts to optimize remote queries to reduce the amount of data transferred from foreign servers. This is done by sending query WHERE clauses to the remote server for execution, and by not retrieving table columns that are not needed for the current query. To reduce the risk of misexecution
of queries, WHERE clauses are not sent to the remote server unless they use only data types, operators, and functions that are built-in or belong to an extension that's listed in the foreign server's extensions option. Operators and functions in such clauses must be IMMUTABLE as well. For an UPDATE or DELETE query, postgres_fdw attempts to optimize the query execution by sending the whole query to the remote server if there are no query WHERE clauses that cannot be sent to the remote server, no local joins for the query, no row-level local BEFORE or AFTER triggers or stored generated columns on the target table, and no CHECK OPTION constraints from parent views. In UPDATE, expressions to assign to target columns must use only built-in data types, IMMUTABLE operators, or IMMUTABLE functions, to reduce the risk of misexecution of the query.

When postgres_fdw encounters a join between foreign tables on the same foreign server, it sends the entire join to the foreign server, unless for some reason it believes that it will be more efficient to fetch rows from each table individually, or unless the table references involved are subject to different user mappings. While sending the JOIN clauses, it takes the same precautions as mentioned above for the WHERE clauses.

The query that is actually sent to the remote server for execution can be examined using EXPLAIN VERBOSE.

F.50.6. Remote Query Execution Environment

In the remote sessions opened by postgres_fdw, the search_path parameter is set to just pg_catalog, so that only built-in objects are visible without schema qualification. This is not an issue for queries generated by postgres_fdw itself, because it always supplies such qualification. However, this can pose a hazard for functions that are executed on the remote server via triggers or rules on remote tables. For example, if a remote table is actually a view, any functions used in that view will be executed with the restricted search path. It is recommended to schema-qualify all names in such functions, or else attach SET search_path options (see CREATE FUNCTION) to such functions to establish their expected search path environment.

postgres_fdw likewise establishes remote session settings for various parameters:

- **TimeZone** is set to UTC
- **DateStyle** is set to ISO
- **IntervalStyle** is set to postgres
- **extra_float_digits** is set to 3 for remote servers 9.0 and newer and is set to 2 for older versions

These are less likely to be problematic than search_path, but can be handled with function SET options if the need arises.

It is not recommended that you override this behavior by changing the session-level settings of these parameters; that is likely to cause postgres_fdw to malfunction.

F.50.7. Cross-Version Compatibility

postgres_fdw can be used with remote servers dating back to PostgreSQL 8.3. Read-only capability is available back to 8.1. A limitation however is that postgres_fdw generally assumes that immutable built-in functions and operators are safe to send to the remote server for execution, if they appear in a WHERE clause for a foreign table. Thus, a built-in function that was added since the remote server's release might be sent to it for execution, resulting in “function does not exist” or a similar error. This type of failure can be worked around by rewriting the query, for example by embedding the foreign table reference in a sub-SELECT with OFFSET 0 as an optimization fence, and placing the problematic function or operator outside the sub-SELECT.

F.50.8. Examples

Here is an example of creating a foreign table with postgres_fdw. First install the extension:

CREATE EXTENSION postgres_fdw;
Then create a foreign server using `CREATE SERVER`. In this example we wish to connect to a Postgres Pro server on host 192.83.123.89 listening on port 5432. The database to which the connection is made is named `foreign_db` on the remote server:

```sql
CREATE SERVER foreign_server
FOREIGN DATA WRAPPER postgres_fdw
OPTIONS (host '192.83.123.89', port '5432', dbname 'foreign_db');
```

A user mapping, defined with `CREATE USER MAPPING`, is needed as well to identify the role that will be used on the remote server:

```sql
CREATE USER MAPPING FOR local_user
SERVER foreign_server
OPTIONS (user 'foreign_user', password 'password');
```

Now it is possible to create a foreign table with `CREATE FOREIGN TABLE`. In this example we wish to access the table named `some_schema.some_table` on the remote server. The local name for it will be `foreign_table`:

```sql
CREATE FOREIGN TABLE foreign_table (id integer NOT NULL, data text)
SERVER foreign_server
OPTIONS (schema_name 'some_schema', table_name 'some_table');
```

It's essential that the data types and other properties of the columns declared in `CREATE FOREIGN TABLE` match the actual remote table. Column names must match as well, unless you attach `column_name` options to the individual columns to show how they are named in the remote table. In many cases, use of `IMPORT FOREIGN SCHEMA` is preferable to constructing foreign table definitions manually.

F.50.9. Author

Shigeru Hanada <shigeru.hanada@gmail.com>

F.51. ptrack

PTRACK is a block-level incremental backup engine for Postgres Pro. If PTRACK is enabled, backup tools like `pg_probackup` can use its API to get information on the changed blocks on the fly when taking incremental backups. Copying only those blocks that have changed since the previous backup can significantly speed up the creation and minimize the size of backups.

PTRACK is designed to allow false positives, but to never allow false negatives: it means that all changes within the data directory except hint bits are guaranteed to be marked in the PTRACK map file, although some unchanged blocks might be included as well.

F.51.1. Setting up PTRACK

Once you complete Postgres Pro Standard installation, do the following:

1. Add `ptrack` to the `shared_preload_libraries` parameter in the `postgresql.conf` file:
   ```
   shared_preload_libraries = 'ptrack'
   ```

2. Set `ptrack.map_size` parameter to a positive integer.

   For optimal performance, it is recommended to set `ptrack.map_size` to $N / 1024$, where $N$ is the size of the Postgres Pro cluster, in MB. If you set this parameter to a lower value, PTRACK is more likely to map several blocks together, which leads to false-positive results when tracking changed blocks and increases the incremental backup size as unchanged blocks can also be copied into the incremental backup.
Setting ptrack.map_size to a higher value does not affect PTRACK operation, but keep in mind that you need up to ptrack.map_size * 3 MB of additional disk space since PTRACK uses two additional temporary files to ensure durability. It is not recommended to set this parameter to a value higher than 1024. Even for Postgres Pro clusters with \( N > 1 \) TB, it makes sense to use a higher value only if the efficiency and sizes of backups are more critical than the potential overhead of maintaining a large PTRACK map.

3. Check the wal_level setting. When using PTRACK, it is required to set the wal_level parameter to replica or higher. Otherwise, you can lose some tracked changes if crash-recovery occurs: some commands do not write WAL at all if wal_level is minimal, and PTRACK map files are flushed to disk only at checkpoint time.

4. Restart the Postgres Pro Standard instance for the changes to take effect, and then create the PTRACK extension:

```sql
CREATE EXTENSION ptrack;
```

As a result, several PTRACK functions are created, which are required for accessing PTRACK data. Once this setup is complete, PTRACK starts tracking all the page changes in the Postgres Pro cluster and creates a `ptrack.map` file that stores the latest LSN values for these pages.

---

**Note**

The ptrack.map_size parameter can only be set at server start. If you change this parameter, the previously created PTRACK map file is cleared, and tracking newly changed blocks starts from scratch. To avoid losing recent changes, it is recommended to retake a full backup after modifying this setting.

---

**F.51.2. PTRACK Configuration Parameters**

`ptrack.map_size` (integer)

Specifies the size of a PTRACK map file and the amount of shared memory allocated for this file, in MB. The PTRACK map file stores the latest LSN values for all pages of the Postgres Pro cluster that have changed since PTRACK was enabled. It is not recommended to set this parameter to a value higher than 1GB. The -1 value disables PTRACK, while the 0 value both disables PTRACK and cleans up all the related service files.

The ptrack.map_size parameter can only be set at server start. If you change this parameter, the previously created PTRACK map file is cleared, and tracking newly changed blocks starts from scratch. To avoid losing recent changes, it is recommended to retake a full backup after modifying this setting.

Default: -1

**F.51.3. PTRACK Functions**

`ptrack_init_lsn()` returns `pg_lsn`

Returns the LSN of the last PTRACK map initialization.

`ptrack_get_pagemapset(lsn pg_lsn)` returns setof `record`

Returns a list of changed data files with bitmaps of changed blocks since the specified LSN.

For example:

```sql
SELECT * FROM ptrack_get_pagemapset('0/2000028');
```

<table>
<thead>
<tr>
<th>path</th>
<th>pagemap</th>
</tr>
</thead>
<tbody>
<tr>
<td>2471</td>
<td></td>
</tr>
</tbody>
</table>
Additional Supplied Modules

ptrack_version() returns text

Returns PTRACK version.

F.52. seg

This module implements a data type seg for representing line segments, or floating point intervals. seg can represent uncertainty in the interval endpoints, making it especially useful for representing laboratory measurements.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.52.1. Rationale

The geometry of measurements is usually more complex than that of a point in a numeric continuum. A measurement is usually a segment of that continuum with somewhat fuzzy limits. The measurements come out as intervals because of uncertainty and randomness, as well as because the value being measured may naturally be an interval indicating some condition, such as the temperature range of stability of a protein.

Using just common sense, it appears more convenient to store such data as intervals, rather than pairs of numbers. In practice, it even turns out more efficient in most applications.

Further along the line of common sense, the fuzziness of the limits suggests that the use of traditional numeric data types leads to a certain loss of information. Consider this: your instrument reads 6.50, and you input this reading into the database. What do you get when you fetch it? Watch:

```
test=> select 6.50 :: float8 as "pH";
     pH
   -----+
      6.5
(1 row)
```

In the world of measurements, 6.50 is not the same as 6.5. It may sometimes be critically different. The experimenters usually write down (and publish) the digits they trust. 6.50 is actually a fuzzy interval contained within a bigger and even fuzzier interval, 6.5, with their center points being (probably) the only common feature they share. We definitely do not want such different data items to appear the same.

Conclusion? It is nice to have a special data type that can record the limits of an interval with arbitrarily variable precision. Variable in the sense that each data element records its own precision.

Check this out:

```
test=> select '6.25 .. 6.50'::seg as "pH";
    pH
  ---------+
     6.25 .. 6.50
(1 row)
```
F.52.2. Syntax

The external representation of an interval is formed using one or two floating-point numbers joined by the range operator (.. or ...). Alternatively, it can be specified as a center point plus or minus a deviation. Optional certainty indicators (<, > or ~) can be stored as well. (Certainty indicators are ignored by all the built-in operators, however.) Table F.79 gives an overview of allowed representations; Table F.80 shows some examples.

In Table F.79, x, y, and delta denote floating-point numbers. x and y, but not delta, can be preceded by a certainty indicator.

<table>
<thead>
<tr>
<th>Table F.79. seg External Representations</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
</tr>
<tr>
<td>x .. y</td>
</tr>
<tr>
<td>x (+-) delta</td>
</tr>
<tr>
<td>x ..</td>
</tr>
<tr>
<td>.. x</td>
</tr>
</tbody>
</table>

Table F.80. Examples of Valid seg Input

| 5.0 | Creates a zero-length segment (a point, if you will) |
| ~5.0 | Creates a zero-length segment and records ~ in the data. ~ is ignored by seg operations, but is preserved as a comment. |
| <5.0 | Creates a point at 5.0. < is ignored but is preserved as a comment. |
| >5.0 | Creates a point at 5.0. > is ignored but is preserved as a comment. |
| 5(+-)0.3 | Creates an interval 4.7 .. 5.3. Note that the (+-) notation isn’t preserved. |
| 50 .. | Everything that is greater than or equal to 50 |
| .. 0 | Everything that is less than or equal to 0 |
| 1.5e-2 .. 2E-2 | Creates an interval 0.015 .. 0.02 |
| 1 ... 2 | The same as 1...2, or 1 .. 2, or 1..2 (spaces around the range operator are ignored) |

Because the ... operator is widely used in data sources, it is allowed as an alternative spelling of the .. operator. Unfortunately, this creates a parsing ambiguity: it is not clear whether the upper bound in 0...23 is meant to be 23 or 0.23. This is resolved by requiring at least one digit before the decimal point in all numbers in seg input.

As a sanity check, seg rejects intervals with the lower bound greater than the upper, for example 5 .. 2.

F.52.3. Precision

seg values are stored internally as pairs of 32-bit floating point numbers. This means that numbers with more than 7 significant digits will be truncated.

Numbers with 7 or fewer significant digits retain their original precision. That is, if your query returns 0.00, you will be sure that the trailing zeroes are not the artifacts of formatting: they reflect the precision of the original data. The number of leading zeroes does not affect precision: the value 0.0067 is considered to have just 2 significant digits.

F.52.4. Usage

The seg module includes a GiST index operator class for seg values. The operators supported by the GiST operator class are shown in Table F.81.
### Table F.81. Seg GiST Operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>seg &lt;&lt; seg</code> → boolean</td>
<td>Is the first <code>seg</code> entirely to the left of the second? <code>[a, b] &lt;&lt; [c, d]</code> is true if <code>b &lt; c</code>.</td>
</tr>
<tr>
<td><code>seg &gt;&gt; seg</code> → boolean</td>
<td>Is the first <code>seg</code> entirely to the right of the second? <code>[a, b] &gt;&gt; [c, d]</code> is true if <code>a &gt; d</code>.</td>
</tr>
<tr>
<td><code>seg &amp;&lt; seg</code> → boolean</td>
<td>Does the first <code>seg</code> not extend to the right of the second? <code>[a, b] &amp;&lt; [c, d]</code> is true if <code>b &lt;= d</code>.</td>
</tr>
<tr>
<td><code>seg &amp;&gt; seg</code> → boolean</td>
<td>Does the first <code>seg</code> not extend to the left of the second? <code>[a, b] &amp;&gt; [c, d]</code> is true if <code>a &gt;= c</code>.</td>
</tr>
<tr>
<td><code>seg = seg</code> → boolean</td>
<td>Are the two <code>seg</code>s equal?</td>
</tr>
<tr>
<td><code>seg &amp;&amp; seg</code> → boolean</td>
<td>Do the two <code>seg</code>s overlap?</td>
</tr>
<tr>
<td><code>seg @&gt; seg</code> → boolean</td>
<td>Does the first <code>seg</code> contain the second?</td>
</tr>
<tr>
<td><code>seg &lt;@ seg</code> → boolean</td>
<td>Is the first <code>seg</code> contained in the second?</td>
</tr>
</tbody>
</table>

In addition to the above operators, the usual comparison operators shown in Table 9.1 are available for type `seg`. These operators first compare `(a)` to `(c)`, and if these are equal, compare `(b)` to `(d)`. That results in reasonably good sorting in most cases, which is useful if you want to use ORDER BY with this type.

### F.52.5. Notes

For examples of usage, see the regression test `sql/seg.sql`.

The mechanism that converts `(+-)` to regular ranges isn't completely accurate in determining the number of significant digits for the boundaries. For example, it adds an extra digit to the lower boundary if the resulting interval includes a power of ten:

```sql
postgres=> select '10(+-)1'::seg as seg;
         seg
---------
   9.0 .. 11             -- should be: 9 .. 11
```

The performance of an R-tree index can largely depend on the initial order of input values. It may be very helpful to sort the input table on the `seg` column; see the script `sort-segments.pl` for an example.

### F.52.6. Credits

Original author: Gene Selkov, Jr. `<selkovjr@mcs.anl.gov>`, Mathematics and Computer Science Division, Argonne National Laboratory.

My thanks are primarily to Prof. Joe Hellerstein ([https://dsf.berkeley.edu/jmh/](https://dsf.berkeley.edu/jmh/)) for elucidating the gist of the GiST ([http://gist.cs.berkeley.edu/](http://gist.cs.berkeley.edu/)). I am also grateful to all Postgres developers, present and past, for enabling myself to create my own world and live undisturbed in it. And I would like to acknowledge my gratitude to Argonne Lab and to the U.S. Department of Energy for the years of faithful support of my database research.

### F.53. sepgsql

2474
sepgsql is a loadable module that supports label-based mandatory access control (MAC) based on SELinux security policy.

**Warning**

The current implementation has significant limitations, and does not enforce mandatory access control for all actions. See Section F.53.7.

### F.53.1. Overview

This module integrates with SELinux to provide an additional layer of security checking above and beyond what is normally provided by Postgres Pro. From the perspective of SELinux, this module allows Postgres Pro to function as a user-space object manager. Each table or function access initiated by a DML query will be checked against the system security policy. This check is in addition to the usual SQL permissions checking performed by Postgres Pro.

SELinux access control decisions are made using security labels, which are represented by strings such as `system_u:object_r:sepgsql_table_t:s0`. Each access control decision involves two labels: the label of the subject attempting to perform the action, and the label of the object on which the operation is to be performed. Since these labels can be applied to any sort of object, access control decisions for objects stored within the database can be (and, with this module, are) subjected to the same general criteria used for objects of any other type, such as files. This design is intended to allow a centralized security policy to protect information assets independent of the particulars of how those assets are stored.

The **SECURITY LABEL** statement allows assignment of a security label to a database object.

### F.53.2. Installation

sepgsql can only be used on Linux 2.6.28 or higher with SELinux enabled. It is not available on any other platform. You will also need libselinux 2.1.10 or higher and selinux-policy 3.9.13 or higher (although some distributions may backport the necessary rules into older policy versions).

The `sestatus` command allows you to check the status of SELinux. A typical display is:

```
$ sestatus
SELinux status: enabled
SELinuxfs mount: /selinux
Current mode: enforcing
Mode from config file: enforcing
Policy version: 24
Policy from config file: targeted
```

If SELinux is disabled or not installed, you must set that product up first before installing this module.

To build this module, include the option `--with-selinux` in your Postgres Pro `configure` command. Be sure that the `libselinux-devel` RPM is installed at build time.

To use this module, you must include `sepgsql` in the `shared_preload_libraries` parameter in `postgresql.conf`. The module will not function correctly if loaded in any other manner. Once the module is loaded, you should execute `sepgsql.sql` in each database. This will install functions needed for security label management, and assign initial security labels.

Here is an example showing how to initialize a fresh database cluster with `sepgsql` functions and security labels installed. Adjust the paths shown as appropriate for your installation:

```
$ export PGDATA=/path/to/data/directory
$ initdb
$ vi $PGDATA/postgresql.conf
   change
   #shared_preload_libraries = '' # (change requires restart)
```
to
  shared_preload_libraries = 'sepgsql'           # (change requires restart)
$ for DBNAME in template0 template1 postgres; do
  postgres --single -F -c exit_on_error=true $DBNAME \ 
    </usr/local/pgsql/share/contrib/sepgsql.sql >/dev/null
done

Please note that you may see some or all of the following notifications depending on the particular
versions you have of libselinux and selinux-policy:

/etc/selinux/targeted/contexts/sepgsql_contexts:  line 33 has invalid object type db_blobs
/etc/selinux/targeted/contexts/sepgsql_contexts:  line 36 has invalid object type db_language
/etc/selinux/targeted/contexts/sepgsql_contexts:  line 37 has invalid object type db_language
/etc/selinux/targeted/contexts/sepgsql_contexts:  line 38 has invalid object type db_language
/etc/selinux/targeted/contexts/sepgsql_contexts:  line 39 has invalid object type db_language
/etc/selinux/targeted/contexts/sepgsql_contexts:  line 40 has invalid object type db_language

These messages are harmless and should be ignored.

If the installation process completes without error, you can now start the server normally.

F.53.3. Regression Tests

Due to the nature of SELinux, running the regression tests for sepgsql requires several extra
configuration steps, some of which must be done as root. The regression tests will not be run by an
ordinary make check or make installcheck command; you must set up the configuration and then
invoke the test script manually. The tests must be run in the contrib/sepgsql directory of a configured
Postgres Pro build tree. Although they require a build tree, the tests are designed to be executed against
an installed server, that is they are comparable to make installcheck not make check.

First, set up sepgsql in a working database according to the instructions in Section F.53.2. Note that the
current operating system user must be able to connect to the database as superuser without password
authentication.

Second, build and install the policy package for the regression test. The sepgsql-regtest policy is a
special purpose policy package which provides a set of rules to be allowed during the regression tests. It
should be built from the policy source file sepgsql-regtest.te, which is done using make with a Makefile
supplied by SELinux. You will need to locate the appropriate Makefile on your system; the path shown
below is only an example. (This Makefile is usually supplied by the selinux-policy-devel or selinux-
policy RPM.) Once built, install this policy package using the semodule command, which loads supplied
policy packages into the kernel. If the package is correctly installed, semodule -l should list sepgsql-
regtest as an available policy package:

$ cd .../contrib/sepgsql
$ make -f /usr/share/selinux/devel/Makefile
$ sudo semodule -u sepgsql-regtest.pp
$ sudo semodule -l | grep sepgsql
sepgsql-regtest 1.07

Third, turn on sepgsql_regression_test_mode. For security reasons, the rules in sepgsql-regtest
are not enabled by default; the sepgsql_regression_test_mode parameter enables the rules needed to
launch the regression tests. It can be turned on using the setsebool command:

$ sudo setsebool sepgsql_regression_test_mode on
$ getsebool sepgsql_regression_test_mode

2476
Additional Supplied Modules

sepgsql_regression_test_mode --> on

Fourth, verify your shell is operating in the unconfined_t domain:

$ id -Z
unconfined_u:unconfined_r:unconfined_t:s0-s0:c0.c1023

See Section F.53.8 for details on adjusting your working domain, if necessary.

Finally, run the regression test script:

$ ./test_sepgsql

This script will attempt to verify that you have done all the configuration steps correctly, and then it will run the regression tests for the sepgsql module.

After completing the tests, it's recommended you disable the sepgsql_regression_test_mode parameter:

$ sudo setsebool sepgsql_regression_test_mode off

You might prefer to remove the sepgsql-regtest policy entirely:

$ sudo semodule -r sepgsql-regtest

F.53.4. GUC Parameters

sepgsql.permissive (boolean)

This parameter enables sepgsql to function in permissive mode, regardless of the system setting. The default is off. This parameter can only be set in the postgresql.conf file or on the server command line.

When this parameter is on, sepgsql functions in permissive mode, even if SELinux in general is working in enforcing mode. This parameter is primarily useful for testing purposes.

sepgsql.debug_audit (boolean)

This parameter enables the printing of audit messages regardless of the system policy settings. The default is off, which means that messages will be printed according to the system settings.

The security policy of SELinux also has rules to control whether or not particular accesses are logged. By default, access violations are logged, but allowed accesses are not.

This parameter forces all possible logging to be turned on, regardless of the system policy.

F.53.5. Features

F.53.5.1. Controlled Object Classes

The security model of SELinux describes all the access control rules as relationships between a subject entity (typically, a client of the database) and an object entity (such as a database object), each of which is identified by a security label. If access to an unlabeled object is attempted, the object is treated as if it were assigned the label unlabeled_t.

Currently, sepgsql allows security labels to be assigned to schemas, tables, columns, sequences, views, and functions. When sepgsql is in use, security labels are automatically assigned to supported database objects at creation time. This label is called a default security label, and is decided according to the system security policy, which takes as input the creator's label, the label assigned to the new object's parent object and optionally name of the constructed object.

A new database object basically inherits the security label of the parent object, except when the security policy has special rules known as type-transition rules, in which case a different label may be applied. For schemas, the parent object is the current database; for tables, sequences, views, and functions, it is the containing schema; for columns, it is the containing table.
F.53.5.2. DML Permissions

For tables, `db_table:select`, `db_table:insert`, `db_table:update` or `db_table:delete` are checked for all the referenced target tables depending on the kind of statement; in addition, `db_table:select` is also checked for all the tables that contain columns referenced in the `WHERE` or `RETURNING` clause, as a data source for `UPDATE`, and so on.

Column-level permissions will also be checked for each referenced column. `db_column:select` is checked on not only the columns being read using `SELECT`, but those being referenced in other DML statements; `db_column:update` or `db_column:insert` will also be checked for columns being modified by `UPDATE` or `INSERT`.

For example, consider:

```
UPDATE t1 SET x = 2, y = func1(y) WHERE z = 100;
```

Here, `db_column:update` will be checked for `t1.x`, since it is being updated, `db_column:{select update}` will be checked for `t1.y`, since it is both updated and referenced, and `db_column:select` will be checked for `t1.z`, since it is only referenced. `db_table:{select update}` will also be checked at the table level.

For sequences, `db_sequence:get_value` is checked when we reference a sequence object using `SELECT`; however, note that we do not currently check permissions on execution of corresponding functions such as `lastval()`.

For views, `db_view:expand` will be checked, then any other required permissions will be checked on the objects being expanded from the view, individually.

For functions, `db_procedure:{execute}` will be checked when user tries to execute a function as a part of query, or using fast-path invocation. If this function is a trusted procedure, it also checks `db_procedure:{entrypoint}` permission to check whether it can perform as entry point of trusted procedure.

In order to access any schema object, `db_schema:search` permission is required on the containing schema. When an object is referenced without schema qualification, schemas on which this permission is not present will not be searched (just as if the user did not have `USAGE` privilege on the schema). If an explicit schema qualification is present, an error will occur if the user does not have the requisite permission on the named schema.

The client must be allowed to access all referenced tables and columns, even if they originated from views which were then expanded, so that we apply consistent access control rules independent of the manner in which the table contents are referenced.

The default database privilege system allows database superusers to modify system catalogs using DML commands, and reference or modify toast tables. These operations are prohibited when `sepgsql` is enabled.

F.53.5.3. DDL Permissions

SELinux defines several permissions to control common operations for each object type; such as creation, alter, drop and relabel of security label. In addition, several object types have special permissions to control their characteristic operations; such as addition or deletion of name entries within a particular schema.

Creating a new database object requires `create` permission. SELinux will grant or deny this permission based on the client's security label and the proposed security label for the new object. In some cases, additional privileges are required:

- `CREATE DATABASE` additionally requires `getattr` permission for the source or template database.
- Creating a schema object additionally requires `add_name` permission on the parent schema.
- Creating a table additionally requires permission to create each individual table column, just as if each table column were a separate top-level object.
• Creating a function marked as LEAKPROOF additionally requires install permission. (This permission is also checked when LEAKPROOF is set for an existing function.)

When DROP command is executed, drop will be checked on the object being removed. Permissions will be also checked for objects dropped indirectly via CASCADE. Deletion of objects contained within a particular schema (tables, views, sequences and procedures) additionally requires remove_name on the schema.

When ALTER command is executed, setattr will be checked on the object being modified for each object types, except for subsidiary objects such as the indexes or triggers of a table, where permissions are instead checked on the parent object. In some cases, additional permissions are required:

• Moving an object to a new schema additionally requires remove_name permission on the old schema and add_name permission on the new one.
• Setting the LEAKPROOF attribute on a function requires install permission.
• Using SECURITY LABEL on an object additionally requires relabelfrom permission for the object in conjunction with its old security label and relabelto permission for the object in conjunction with its new security label. (In cases where multiple label providers are installed and the user tries to set a security label, but it is not managed by SELinux, only setattr should be checked here. This is currently not done due to implementation restrictions.)

F.53.5.4. Trusted Procedures

Trusted procedures are similar to security definer functions or setuid commands. SELinux provides a feature to allow trusted code to run using a security label different from that of the client, generally for the purpose of providing highly controlled access to sensitive data (e.g., rows might be omitted, or the precision of stored values might be reduced). Whether or not a function acts as a trusted procedure is controlled by its security label and the operating system security policy. For example:

```
postgres=# CREATE TABLE customer (cid int primary key, cname text, credit text);
CREATE TABLE
postgres=# SECURITY LABEL ON COLUMN customer.credit IS 'system_u:object_r:sepgsql_secret_table_t:s0';
SECURITY LABEL
postgres=# CREATE FUNCTION show_credit(int) RETURNS text AS 'SELECT regexp_replace(credit, '-[0-9]+$'', '-xxxx''', 'g') FROM customer WHERE cid = $1' LANGUAGE sql;
CREATE FUNCTION
postgres=# SECURITY LABEL ON FUNCTION show_credit(int) IS 'system_u:object_r:sepgsql_trusted_proc_exec_t:s0';
SECURITY LABEL
```

The above operations should be performed by an administrative user.

```
postgres=# SELECT * FROM customer;
ERROR:  SELinux: security policy violation
postgres=# SELECT cid, cname, show_credit(cid) FROM customer;
    cid |        cname         | show_credit
----------+---------------------+---------------------
     1 | taro               | 1111-2222-3333-xxxx
     2 | hanako             | 5555-6666-7777-xxxx
(2 rows)
```

In this case, a regular user cannot reference customer.credit directly, but a trusted procedure show_credit allows the user to print the credit card numbers of customers with some of the digits masked out.
F.53.5.5. Dynamic Domain Transitions

It is possible to use SELinux's dynamic domain transition feature to switch the security label of the client process, the client domain, to a new context, if that is allowed by the security policy. The client domain needs the `setcurrent` permission and also `dyntransition` from the old to the new domain.

Dynamic domain transitions should be considered carefully, because they allow users to switch their label, and therefore their privileges, at their option, rather than (as in the case of a trusted procedure) as mandated by the system. Thus, the `dyntransition` permission is only considered safe when used to switch to a domain with a smaller set of privileges than the original one. For example:

```sql
regression=# select sepgsql_getcon();
sepgsql_getcon
-----------------
unconfined_u:unconfined_r:unconfined_t:s0-s0:c0.c1023
(1 row)
regression=# SELECT sepgsql_setcon('unconfined_u:unconfined_r:unconfined_t:s0-s0:c1.c4');
sepgsql_setcon
-------------
t
(1 row)
regression=# SELECT sepgsql_setcon('unconfined_u:unconfined_r:unconfined_t:s0-s0:c1.c1023');
ERROR:  SELinux: security policy violation
```

In this example above we were allowed to switch from the larger MCS range `c1.c1023` to the smaller range `c1.c4`, but switching back was denied.

A combination of dynamic domain transition and trusted procedure enables an interesting use case that fits the typical process life-cycle of connection pooling software. Even if your connection pooling software is not allowed to run most of SQL commands, you can allow it to switch the security label of the client using the `sepgsql_setcon()` function from within a trusted procedure; that should take some credential to authorize the request to switch the client label. After that, this session will have the privileges of the target user, rather than the connection pooler. The connection pooler can later revert the security label change by again using `sepgsql_setcon()` with NULL argument, again invoked from within a trusted procedure with appropriate permissions checks. The point here is that only the trusted procedure actually has permission to change the effective security label, and only does so when given proper credentials. Of course, for secure operation, the credential store (table, procedure definition, or whatever) must be protected from unauthorized access.

F.53.5.6. Miscellaneous

We reject the `LOAD` command across the board, because any module loaded could easily circumvent security policy enforcement.

F.53.6. Sepgsql Functions

Table F.82 shows the available functions.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sepgsql_getcon  ()→text</td>
<td>Returns the client domain, the current security label of the client.</td>
</tr>
<tr>
<td>sepgsql_setcon  (text)→boolean</td>
<td></td>
</tr>
</tbody>
</table>
Additional Supplied Modules

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sepgsql_mcstrans_in</td>
<td>Translates the given qualified MLS/MCS range into raw format if the mcstrans daemon is running.</td>
</tr>
<tr>
<td>sepgsql_mcstrans_out</td>
<td>Translates the given raw MLS/MCS range into qualified format if the mcstrans daemon is running.</td>
</tr>
<tr>
<td>sepgsql_restorecon</td>
<td>Sets up initial security labels for all objects within the current database. The argument may be NULL, or the name of a specfile to be used as alternative of the system default.</td>
</tr>
</tbody>
</table>

### F.53.7. Limitations

**Data Definition Language (DDL) Permissions**

Due to implementation restrictions, some DDL operations do not check permissions.

**Data Control Language (DCL) Permissions**

Due to implementation restrictions, DCL operations do not check permissions.

**Row-level access control**

Postgres Pro supports row-level access, but sepgsql does not.

**Covert channels**

sepgsql does not try to hide the existence of a certain object, even if the user is not allowed to reference it. For example, we can infer the existence of an invisible object as a result of primary key conflicts, foreign key violations, and so on, even if we cannot obtain the contents of the object. The existence of a top secret table cannot be hidden; we only hope to conceal its contents.

### F.53.8. External Resources

**SE-PostgreSQL Introduction**

This wiki page provides a brief overview, security design, architecture, administration and upcoming features.

**SELinux User's and Administrator's Guide**

This document provides a wide spectrum of knowledge to administer SELinux on your systems. It focuses primarily on Red Hat operating systems, but is not limited to them.

**Fedora SELinux FAQ**

This document answers frequently asked questions about SELinux. It focuses primarily on Fedora, but is not limited to Fedora.

### F.53.9. Author

KaiGai Kohei <kaigai@ak.jp.nec.com>

### F.54. shared_ispell

The shared_ispell module provides a shared ispell dictionary, i.e. a dictionary that's stored in shared segment. The traditional ispell implementation means that each session initializes and stores the dictionary on it's own, which means a lot of CPU/RAM is wasted.
This extension allocates an area in shared segment (you have to choose the size in advance) and then loads the dictionary into it when it's used for the first time.

**F.54.1. Functions**

The functions provided by the `shared_ispell` module are shown in Table F.83.

<table>
<thead>
<tr>
<th>Function</th>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>shared_ispell_reset()</td>
<td>void</td>
<td>Resets the dictionaries (e.g. so that you can reload the updated files from disk). The sessions that already use the dictionaries will be forced to reinitialize them.</td>
</tr>
<tr>
<td>shared_ispell_mem_used()</td>
<td>int</td>
<td>Returns a value of used memory of the shared segment by loaded shared dictionaries in bytes.</td>
</tr>
<tr>
<td>shared_ispell_mem_available()</td>
<td>int</td>
<td>Returns a value of available memory of the shared segment.</td>
</tr>
<tr>
<td>shared_ispell_dicts()</td>
<td>setof</td>
<td>Returns a list of dictionaries loaded in the shared segment.</td>
</tr>
<tr>
<td>shared_ispell_stoplists()</td>
<td>setof</td>
<td>Returns a list of stopwords loaded in the shared segment.</td>
</tr>
</tbody>
</table>

**F.54.2. GUC Parameters**

`shared_ispell.max_size(int)`

Defines the maximum size of the shared segment. This is a hard limit, the shared segment is not extensible and you need to set it so that all the dictionaries fit into it and not much memory is wasted.

**F.54.3. Using the dictionary**

The module needs to allocate space in the shared memory segment. So add this to the config file (or update the current values):

```
# libraries to load
shared_preload_libraries = 'shared_ispell'

# config of the shared memory
shared_ispell.max_size = 32MB
```

To find out how much memory you actually need, use a large value (e.g. 200MB) and load all the dictionaries you want to use. Then use the `shared_ispell_mem_used()` function to find out how much memory was actually used (and set the `shared_ispell.max_size` GUC variable accordingly).

Don’t set it exactly to that value, leave there some free space, so that you can reload the dictionaries without changing the GUC max_size limit (which requires a restart of the DB). Something like 512kB should be just fine.

The extension defines a `shared_ispell` template that you may use to define custom dictionaries. E.g. you may do this:

```sql
CREATE TEXT SEARCH DICTIONARY english_shared (  
    TEMPLATE = shared_ispell,  
    DictFile = en_us,  
    AffFile = en_us,
```

2482
Additional Supplied Modules

StopWords = english
);

CREATE TEXT SEARCH CONFIGURATION public.english_shared
  ( COPY = pg_catalog.simple );

ALTER TEXT SEARCH CONFIGURATION english_shared
  ALTER MAPPING FOR asciiword, asciihword, hword_asciipart,
    word, hword, hword_part
  WITH english_shared, english_stem;

We can test created configuration:

SELECT * FROM ts_debug('english_shared', 'abilities');

<table>
<thead>
<tr>
<th>alias</th>
<th>description</th>
<th>token</th>
<th>dictionaries</th>
<th>dictionary</th>
</tr>
</thead>
<tbody>
<tr>
<td>asciiword</td>
<td>Word, all ASCII</td>
<td>abilities</td>
<td>{english_shared,english_stem}</td>
<td></td>
</tr>
</tbody>
</table>
| english_shared | {ability} | (1 row)

Or you can update your own text search configuration. For example, you have the public.english dictionary. You can update it to use the shared_ispell template:

ALTER TEXT SEARCH CONFIGURATION public.english
  ALTER MAPPING FOR asciiword, asciihword, hword_asciipart,
    word, hword, hword_part
  WITH english_shared, english_stem;

Tomas Vondra <tomas.vondra@2ndquadrant.com>, Prague, Czech Republic

F.55. spi

The spi module provides several workable examples of using the Server Programming Interface (SPI) and triggers. While these functions are of some value in their own right, they are even more useful as examples to modify for your own purposes. The functions are general enough to be used with any table, but you have to specify table and field names (as described below) while creating a trigger.

Each of the groups of functions described below is provided as a separately-installable extension.

F.55.1. refint — Functions for Implementing Referential Integrity

check_primary_key() and check_foreign_key() are used to check foreign key constraints. (This functionality is long since superseded by the built-in foreign key mechanism, of course, but the module is still useful as an example.)

check_primary_key() checks the referencing table. To use, create a BEFORE INSERT OR UPDATE trigger using this function on a table referencing another table. Specify as the trigger arguments: the referencing table's column name(s) which form the foreign key, the referenced table name, and the column names in the referenced table which form the primary/unique key. To handle multiple foreign keys, create a trigger for each reference.

check_foreign_key() checks the referenced table. To use, create a BEFORE DELETE OR UPDATE trigger using this function on a table referenced by other table(s). Specify as the trigger arguments: the number of referencing tables for which the function has to perform checking, the action if a referencing key is found (cascade — to delete the referencing row, restrict — to abort transaction if referencing keys exist, setnull — to set referencing key fields to null), the triggered table's column names which form the primary/unique key, then the referencing table name and column names (repeated for as many
Additional Supplied Modules

referencing tables as were specified by first argument). Note that the primary/unique key columns should be marked NOT NULL and should have a unique index.

There are examples in refint.example.

**F.55.2. autoinc — Functions for Autoincrementing Fields**

autoinc() is a trigger that stores the next value of a sequence into an integer field. This has some overlap with the built-in “serial column” feature, but it is not the same: autoinc() will override attempts to substitute a different field value during inserts, and optionally it can be used to increment the field during updates, too.

To use, create a BEFORE INSERT (or optionally BEFORE INSERT OR UPDATE) trigger using this function. Specify two trigger arguments: the name of the integer column to be modified, and the name of the sequence object that will supply values. (Actually, you can specify any number of pairs of such names, if you’d like to update more than one autoincrementing column.)

There is an example in autoinc.example.

**F.55.3. insert_username — Functions for Tracking Who Changed a Table**

insert_username() is a trigger that stores the current user's name into a text field. This can be useful for tracking who last modified a particular row within a table.

To use, create a BEFORE INSERT and/or UPDATE trigger using this function. Specify a single trigger argument: the name of the text column to be modified.

There is an example in insert_username.example.

**F.55.4. moddatetime — Functions for Tracking Last Modification Time**

moddatetime() is a trigger that stores the current time into a timestamp field. This can be useful for tracking the last modification time of a particular row within a table.

To use, create a BEFORE UPDATE trigger using this function. Specify a single trigger argument: the name of the column to be modified. The column must be of type timestamp or timestamp with time zone.

There is an example in moddatetime.example.

**F.56. sslinfo**

The sslinfo module provides information about the SSL certificate that the current client provided when connecting to Postgres Pro. The module is useless (most functions will return NULL) if the current connection does not use SSL.

Some of the information available through this module can also be obtained using the built-in system view pg_stat_ssl.

This extension won’t build at all unless the installation was configured with --with-ssl=openssl.

**F.56.1. Functions Provided**

ssl_is_used() returns boolean

Returns true if current connection to server uses SSL, and false otherwise.

ssl_version() returns text

Returns the name of the protocol used for the SSL connection (e.g., TLSv1.0, TLSv1.1, TLSv1.2 or TLSv1.3).
ssl_cipher() returns text

Returns the name of the cipher used for the SSL connection (e.g., DHE-RSA-AES256-SHA).

ssl_client_cert_present() returns boolean

Returns true if current client has presented a valid SSL client certificate to the server, and false otherwise. (The server might or might not be configured to require a client certificate.)

ssl_client_serial() returns numeric

Returns serial number of current client certificate. The combination of certificate serial number and certificate issuer is guaranteed to uniquely identify a certificate (but not its owner — the owner ought to regularly change their keys, and get new certificates from the issuer).

So, if you run your own CA and allow only certificates from this CA to be accepted by the server, the serial number is the most reliable (albeit not very mnemonic) means to identify a user.

ssl_client_dn() returns text

Returns the full subject of the current client certificate, converting character data into the current database encoding. It is assumed that if you use non-ASCII characters in the certificate names, your database is able to represent these characters, too. If your database uses the SQL_ASCII encoding, non-ASCII characters in the name will be represented as UTF-8 sequences.

The result looks like /CN=Somebody /C=Some country/O=Some organization.

ssl_issuer_dn() returns text

Returns the full issuer name of the current client certificate, converting character data into the current database encoding. Encoding conversions are handled the same as for ssl_client_dn.

The combination of the return value of this function with the certificate serial number uniquely identifies the certificate.

This function is really useful only if you have more than one trusted CA certificate in your server’s certificate authority file, or if this CA has issued some intermediate certificate authority certificates.

ssl_client_dn_field(fieldname text) returns text

This function returns the value of the specified field in the certificate subject, or NULL if the field is not present. Field names are string constants that are converted into ASN1 object identifiers using the OpenSSL object database. The following values are acceptable:

- commonName (alias CN)
- surname (alias SN)
- name
- givenName (alias GN)
- countryName (alias C)
- localityName (alias L)
- stateOrProvinceName (alias ST)
- organizationName (alias O)
- organizationalUnitName (alias OU)
- title
- description
- initials
- postalCode
- streetAddress
- generationQualifier
- description
dnQualifier
- x500UniqueIdentifier
- pseudonym
role
emailAddress

All of these fields are optional, except commonName. It depends entirely on your CA’s policy which of
them would be included and which wouldn’t. The meaning of these fields, however, is strictly defined
by the X.500 and X.509 standards, so you cannot just assign arbitrary meaning to them.

ssl_issuer_field(fieldname text) returns text

Same as ssl_client_dn_field, but for the certificate issuer rather than the certificate subject.

ssl_extension_info() returns setof record

Provide information about extensions of client certificate: extension name, extension value, and if
it is a critical extension.

F.56.2. Author

Victor Wagner <vitus@cryptocom.ru>, Cryptocom LTD

Dmitry Voronin <carriingfate92@yandex.ru>

E-Mail of Cryptocom OpenSSL development group: <openssl@cryptocom.ru>

F.57. tablefunc

The tablefunc module includes various functions that return tables (that is, multiple rows). These
functions are useful both in their own right and as examples of how to write C functions that return
multiple rows.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE
privilege on the current database.

F.57.1. Functions Provided

Table F.84 summarizes the functions provided by the tablefunc module.

Table F.84. tablefunc Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>normal_rand(numvals integer, mean float8, stddev float8)→setof float8</td>
<td>Produces a set of normally distributed random values.</td>
</tr>
<tr>
<td>crosstab(sql text )→setof record</td>
<td>Produces a “pivot table” containing row names plus N value columns, where N is determined by the row type specified in the calling query.</td>
</tr>
<tr>
<td>crosstabN(sql text )→setof table_crosstab_ N</td>
<td>Produces a “pivot table” containing row names plus N value columns. crosstab2, crosstab3, and crosstab4 are predefined, but you can create additional crosstabN functions as described below.</td>
</tr>
<tr>
<td>crosstab(source_sql text, category_sql text )→setof record</td>
<td>Produces a “pivot table” with the value columns specified by a second query.</td>
</tr>
<tr>
<td>crosstab(sql text, N integer )→setof record</td>
<td>Obsolete version of crosstab(text) . The parameter N is now ignored, since the number of value columns is always determined by the calling query.</td>
</tr>
<tr>
<td>connectby (relname text, keyid_fld text, parent_keyid_fld text [, orderby_fld text ], start_with text, max_depth integer [, branch_delim text ] )→setof record</td>
<td></td>
</tr>
</tbody>
</table>

2486
### F.57.1.1. normal_rand

normal_rand(int numvals, float8 mean, float8 stddev) returns setof float8

normal_rand produces a set of normally distributed random values (Gaussian distribution).

*numvals* is the number of values to be returned from the function. *mean* is the mean of the normal distribution of values and *stddev* is the standard deviation of the normal distribution of values.

For example, this call requests 1000 values with a mean of 5 and a standard deviation of 3:

```sql
test=# SELECT * FROM normal_rand(1000, 5, 3);
```

```
<table>
<thead>
<tr>
<th>normal_rand</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.56556322244898</td>
</tr>
<tr>
<td>9.10040991424657</td>
</tr>
<tr>
<td>5.36957140345079</td>
</tr>
<tr>
<td>-0.369151492880995</td>
</tr>
<tr>
<td>0.283600703686639</td>
</tr>
<tr>
<td>...</td>
</tr>
<tr>
<td>4.82992125404908</td>
</tr>
<tr>
<td>9.71308014517282</td>
</tr>
<tr>
<td>2.49639286969028</td>
</tr>
</tbody>
</table>

(1000 rows)
```

### F.57.1.2. crosstab(text)

crosstab(text sql)
crosstab(text sql, int N)

The *crosstab* function is used to produce “pivot” displays, wherein data is listed across the page rather than down. For example, we might have data like

```
row1    val11
row1    val12
row1    val13
...
row2    val21
row2    val22
row2    val23
...
```

which we wish to display like

```
row1    val11    val12    val13    ...
row2    val21    val22    val23    ...
...
```

The *crosstab* function takes a text parameter that is an SQL query producing raw data formatted in the first way, and produces a table formatted in the second way.

The *sql* parameter is an SQL statement that produces the source set of data. This statement must return one *row_name* column, one *category* column, and one *value* column. *N* is an obsolete parameter, ignored if supplied (formerly this had to match the number of output value columns, but now that is determined by the calling query).

For example, the provided query might produce a set something like:
The `crosstab` function is declared to return `setof record`, so the actual names and types of the output columns must be defined in the `FROM` clause of the calling `SELECT` statement, for example:

```sql
SELECT * FROM crosstab('...') AS ct(row_name text, category_1 text, category_2 text);
```

This example produces a set something like:

```
<== value  columns  ==>
 row_name   category_1   category_2
----------+------------+------------
 row1        val1         val2
 row2        val5         val6
```

The `FROM` clause must define the output as one `row_name` column (of the same data type as the first result column of the SQL query) followed by N `value` columns (all of the same data type as the third result column of the SQL query). You can set up as many output value columns as you wish. The names of the output columns are up to you.

The `crosstab` function produces one output row for each consecutive group of input rows with the same `row_name` value. It fills the output `value` columns, left to right, with the `value` fields from these rows. If there are fewer rows in a group than there are output `value` columns, the extra output columns are filled with nulls; if there are more rows, the extra input rows are skipped.

In practice the SQL query should always specify `ORDER BY 1,2` to ensure that the input rows are properly ordered, that is, values with the same `row_name` are brought together and correctly ordered within the row. Notice that `crosstab` itself does not pay any attention to the second column of the query result; it's just there to be ordered by, to control the order in which the third-column values appear across the page.

Here is a complete example:

```sql
CREATE TABLE ct(id SERIAL, rowid TEXT, attribute TEXT, value TEXT);
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att1','val1');
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att2','val2');
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att3','val3');
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att4','val4');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att1','val5');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att2','val6');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att3','val7');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att4','val8');

SELECT *
FROM crosstab('select rowid, attribute, value
               from ct
               where attribute = ''att2'' or attribute = ''att3''
               order by 1,2')
       AS ct(row_name text, category_1 text, category_2 text, category_3 text);
```

```
 row_name | category_1 | category_2 | category_3
----------|------------|------------|------------
```
You can avoid always having to write out a `FROM` clause to define the output columns, by setting up a custom crosstab function that has the desired output row type wired into its definition. This is described in the next section. Another possibility is to embed the required `FROM` clause in a view definition.

**Note**

See also the `\crosstabview` command in psql, which provides functionality similar to `crosstab()`.

---

### F.57.1.3. crosstabN(text)

`crosstabN(text sql)`

The `crosstabN` functions are examples of how to set up custom wrappers for the general crosstab function, so that you need not write out column names and types in the calling `SELECT` query. The `tablefunc` module includes `crosstab2`, `crosstab3`, and `crosstab4`, whose output row types are defined as

```sql
CREATE TYPE tablefunc_crosstab_N AS (
    row_name TEXT,
    category_1 TEXT,
    category_2 TEXT,
    ...
    category_N TEXT
);
```

Thus, these functions can be used directly when the input query produces `row_name` and `value` columns of type `text`, and you want 2, 3, or 4 output values columns. In all other ways they behave exactly as described above for the general `crosstab` function.

For instance, the example given in the previous section would also work as

```sql
SELECT *
FROM crosstab3(
    'select rowid, attribute, value
    from ct
    where attribute = ''att2'' or attribute = ''att3''
    order by 1,2');
```

These functions are provided mostly for illustration purposes. You can create your own return types and functions based on the underlying `crosstab()` function. There are two ways to do it:

- Create a composite type describing the desired output columns, similar to the examples in `contrib/tablefunc/tablefunc--1.0.sql`. Then define a unique function name accepting one `text` parameter and returning `setof your_type_name`, but linking to the same underlying `crosstab()` function. For example, if your source data produces `row_names` that are `text`, and values that are `float8`, and you want 5 value columns:

```sql
CREATE TYPE my_crosstab_float8_5_cols AS (
    my_row_name text,
    my_category_1 float8,
    my_category_2 float8,
    my_category_3 float8,
    my_category_4 float8,
    my_category_5 float8
);```
Additional Supplied Modules

my_category_5 float8
;

CREATE OR REPLACE FUNCTION crosstab_float8_5_cols(text)
RETURNS setof my_crosstab_float8_5_cols
AS '$libdir/tablefunc','crosstab' LANGUAGE C STABLE STRICT;

• Use OUT parameters to define the return type implicitly. The same example could also be done this way:

CREATE OR REPLACE FUNCTION crosstab_float8_5_cols(
  IN text,
  OUT my_row_name text,
  OUT my_category_1 float8,
  OUT my_category_2 float8,
  OUT my_category_3 float8,
  OUT my_category_4 float8,
  OUT my_category_5 float8)
RETURNS setof record
AS '$libdir/tablefunc','crosstab' LANGUAGE C STABLE STRICT;

F.57.1.4. crosstab(text, text)

crosstab(text source_sql, text category_sql)

The main limitation of the single-parameter form of crosstab is that it treats all values in a group alike, inserting each value into the first available column. If you want the value columns to correspond to specific categories of data, and some groups might not have data for some of the categories, that doesn't work well. The two-parameter form of crosstab handles this case by providing an explicit list of the categories corresponding to the output columns.

source_sql is an SQL statement that produces the source set of data. This statement must return one row_name column, one category column, and one value column. It may also have one or more “extra” columns. The row_name column must be first. The category and value columns must be the last two columns, in that order. Any columns between row_name and category are treated as “extra”. The “extra” columns are expected to be the same for all rows with the same row_name value.

For example, source_sql might produce a set something like:

```
SELECT row_name, extra_col, cat, value FROM foo ORDER BY 1;
```

<table>
<thead>
<tr>
<th>row_name</th>
<th>extra_col</th>
<th>cat</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>row1</td>
<td>extra1</td>
<td>cat1</td>
<td>val1</td>
</tr>
<tr>
<td>row1</td>
<td>extra1</td>
<td>cat2</td>
<td>val2</td>
</tr>
<tr>
<td>row1</td>
<td>extra1</td>
<td>cat4</td>
<td>val4</td>
</tr>
<tr>
<td>row2</td>
<td>extra2</td>
<td>cat1</td>
<td>val5</td>
</tr>
<tr>
<td>row2</td>
<td>extra2</td>
<td>cat2</td>
<td>val6</td>
</tr>
<tr>
<td>row2</td>
<td>extra2</td>
<td>cat3</td>
<td>val7</td>
</tr>
<tr>
<td>row2</td>
<td>extra2</td>
<td>cat4</td>
<td>val8</td>
</tr>
</tbody>
</table>

category_sql is an SQL statement that produces the set of categories. This statement must return only one column. It must produce at least one row, or an error will be generated. Also, it must not produce duplicate values, or an error will be generated. category_sql might be something like:

```
SELECT DISTINCT cat FROM foo ORDER BY 1;
```

<table>
<thead>
<tr>
<th>cat</th>
</tr>
</thead>
<tbody>
<tr>
<td>cat1</td>
</tr>
<tr>
<td>cat2</td>
</tr>
<tr>
<td>cat3</td>
</tr>
</tbody>
</table>
The **crosstab** function is declared to return `setof record`, so the actual names and types of the output columns must be defined in the **FROM clause** of the calling **SELECT** statement, for example:

```sql
SELECT * FROM crosstab('...', '...')
AS ct(row_name text, extra text, cat1 text, cat2 text, cat3 text, cat4 text);
```

This will produce a result something like:

```
<== value columns ==>   
row_name extra  cat1  cat2  cat3  cat4
---------+-------+------+------+------+------
row1     extra1  val1  val2          val4
row2     extra2  val5  val6   val7   val8
```

The **FROM clause** must define the proper number of output columns of the proper data types. If there are \(N\) columns in the **source_sql** query's result, the first \(N-2\) of them must match up with the first \(N-2\) output columns. The remaining output columns must have the type of the last column of the **source_sql** query's result, and there must be exactly as many of them as there are rows in the **category_sql** query's result.

The **crosstab** function produces one output row for each consecutive group of input rows with the same **row_name** value. The output **row_name** column, plus any “extra” columns, are copied from the first row of the group. The output **value** columns are filled with the **value** fields from rows having matching **category** values. If a row's **category** does not match any output of the **category_sql** query, its **value** is ignored. Output columns whose matching category is not present in any input row of the group are filled with nulls.

In practice the **source_sql** query should always specify `ORDER BY 1` to ensure that values with the same **row_name** are brought together. However, ordering of the categories within a group is not important. Also, it is essential to be sure that the order of the **category_sql** query’s output matches the specified output column order.

Here are two complete examples:

```sql
create table sales(year int, month int, qty int);
insert into sales values(2007, 1, 1000);
insert into sales values(2007, 2, 1500);
insert into sales values(2007, 7, 500);
insert into sales values(2007, 11, 1500);
insert into sales values(2007, 12, 2000);
insert into sales values(2008, 1, 1000);

select * from crosstab(  
  'select year, month, qty from sales order by 1',  
  'select m from generate_series(1,12) m'  
) as (  
  year int,  
  "Jan" int,  
  "Feb" int,  
  "Mar" int,  
  "Apr" int,  
  "May" int,  
  "Jun" int,  
  "Jul" int,  
  "Aug" int,  
  "Sep" int,  
  "Oct" int,  
  "Nov" int,  
  "Dec" int
```

2491
CREATE TABLE cth(rowid text, rowdt timestamp, attribute text, val text);
INSERT INTO cth VALUES('test1','01 March 2003','temperature','42');
INSERT INTO cth VALUES('test1','01 March 2003','test_result','PASS');
INSERT INTO cth VALUES('test1','01 March 2003','volts','2.6987');
INSERT INTO cth VALUES('test2','02 March 2003','temperature','53');
INSERT INTO cth VALUES('test2','02 March 2003','test_result','FAIL');
INSERT INTO cth VALUES('test2','02 March 2003','test_startdate','01 March 2003');
INSERT INTO cth VALUES('test2','02 March 2003','volts','3.1234');

SELECT * FROM crosstab
{
  'SELECT rowid, rowdt, attribute, val FROM cth ORDER BY 1',
  'SELECT DISTINCT attribute FROM cth ORDER BY 1'
}
AS
{
  rowid text,
  rowdt timestamp,
  temperature int4,
  test_result text,
  test_startdate timestamp,
  volts float8
};

| rowid |          rowdt           | temperature | test_result |      test_startdate |
|-------|--------------------------|-------------+-------------|---------------------|
|       |                         | 42          | PASS        |                    |
|       |                         | 2.6987      |             |                    |
| test2 | Sun Mar 02 00:00:00 2003 | 53          | FAIL        | Sat Mar 01 00:00:00 |
|       | 3.1234                  |             |             |                    |

You can create predefined functions to avoid having to write out the result column names and types in each query. See the examples in the previous section. The underlying C function for this form of crosstab is named crosstab_hash.

**F.57.1.5. connectby**

connectby(text relname, text keyid_fld, text parent_keyid_fld [, text orderby_fld ], text start_with, int max_depth [, text branch_delim ])

The connectby function produces a display of hierarchical data that is stored in a table. The table must have a key field that uniquely identifies rows, and a parent-key field that references the parent (if any) of each row. connectby can display the sub-tree descending from any row.

Table F.85 explains the parameters.

**Table F.85. connectby Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>relname</td>
<td>Name of the source relation</td>
</tr>
</tbody>
</table>
### Parameter Description

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>keyidFld</td>
<td>Name of the key field</td>
</tr>
<tr>
<td>parent_keyidFld</td>
<td>Name of the parent-key field</td>
</tr>
<tr>
<td>orderbyFld</td>
<td>Name of the field to order siblings by (optional)</td>
</tr>
<tr>
<td>startWith</td>
<td>Key value of the row to start at</td>
</tr>
<tr>
<td>maxDepth</td>
<td>Maximum depth to descend to, or zero for unlimited depth</td>
</tr>
<tr>
<td>branchDelim</td>
<td>String to separate keys with in branch output (optional)</td>
</tr>
</tbody>
</table>

The key and parent-key fields can be any data type, but they must be the same type. Note that the `startWith` value must be entered as a text string, regardless of the type of the key field.

The `connectby` function is declared to return `setof record`, so the actual names and types of the output columns must be defined in the `FROM` clause of the calling `SELECT` statement, for example:

```sql
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'pos', 'row2', 0, '')
AS t(keyid text, parent_keyid text, level int, branch text, pos int);
```

The first two output columns are used for the current row's key and its parent row's key; they must match the type of the table's key field. The third output column is the depth in the tree and must be of type `integer`. If a `branchDelim` parameter was given, the next output column is the branch display and must be of type `text`. Finally, if an `orderbyFld` parameter was given, the last output column is a serial number, and must be of type `integer`.

The “branch” output column shows the path of keys taken to reach the current row. The keys are separated by the specified `branchDelim` string. If no branch display is wanted, omit both the `branchDelim` parameter and the branch column in the output column list.

If the ordering of siblings of the same parent is important, include the `orderbyFld` parameter to specify which field to order siblings by. This field can be of any sortable data type. The output column list must include a final integer serial-number column, if and only if `orderbyFld` is specified.

The parameters representing table and field names are copied as-is into the SQL queries that `connectby` generates internally. Therefore, include double quotes if the names are mixed-case or contain special characters. You may also need to schema-qualify the table name.

In large tables, performance will be poor unless there is an index on the parent-key field.

It is important that the `branchDelim` string not appear in any key values, else `connectby` may incorrectly report an infinite-recursion error. Note that if `branchDelim` is not provided, a default value of `-` is used for recursion detection purposes.

Here is an example:

```sql
CREATE TABLE connectby_tree(keyid text, parent_keyid text, pos int);

INSERT INTO connectby_tree VALUES('row1',NULL, 0);
INSERT INTO connectby_tree VALUES('row2','row1', 0);
INSERT INTO connectby_tree VALUES('row3','row1', 0);
INSERT INTO connectby_tree VALUES('row4','row2', 0);
INSERT INTO connectby_tree VALUES('row5','row2', 0);
INSERT INTO connectby_tree VALUES('row6','row4', 0);
INSERT INTO connectby_tree VALUES('row7','row3', 0);
INSERT INTO connectby_tree VALUES('row8','row6', 0);
INSERT INTO connectby_tree VALUES('row9','row5', 0);
```

2493
### Additional Supplied Modules

-- with branch, without orderby_fld (order of results is not guaranteed)

```sql
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'row2', 0, '~')
AS t(keyid text, parent_keyid text, level int, branch text);
```

<table>
<thead>
<tr>
<th>keyid</th>

### F.57.2. Author

Joe Conway

### F.58. tcn

2494
The `tcn` module provides a trigger function that notifies listeners of changes to any table on which it is attached. It must be used as an **AFTER trigger** **FOR EACH ROW**.

This module is considered “trusted”, that is, it can be installed by non-superusers who have **CREATE** privilege on the current database.

Only one parameter may be supplied to the function in a **CREATE TRIGGER** statement, and that is optional. If supplied it will be used for the channel name for the notifications. If omitted `tcn` will be used for the channel name.

The payload of the notifications consists of the table name, a letter to indicate which type of operation was performed, and column name/value pairs for primary key columns. Each part is separated from the next by a comma. For ease of parsing using regular expressions, table and column names are always wrapped in double quotes, and data values are always wrapped in single quotes. Embedded quotes are doubled.

A brief example of using the extension follows.

```sql
test=# create table tcndata
    (a int not null,
     b date not null,
     c text,
     primary key (a, b))
CREATE TABLE

CREATE TRIGGER tcndata_tcn_trigger
    after insert or update or delete on tcndata
    for each row execute function triggered_change_notification();

CREATE TRIGGER

LISTEN

Asynchronous notification "tcn" with payload ""tcndata",I,"a"='1","b"='2012-12-22'" received from server process with PID 22770.
Asynchronous notification "tcn" with payload ""tcndata",I,"a"='1","b"='2012-12-23'" received from server process with PID 22770.
Asynchronous notification "tcn" with payload ""tcndata",I,"a"='2","b"='2012-12-23'" received from server process with PID 22770.

Asynchronous notification "tcn" with payload ""tcndata",U,"a"='1","b"='2012-12-22'" received from server process with PID 22770.
Asynchronous notification "tcn" with payload ""tcndata",U,"a"='1","b"='2012-12-23'" received from server process with PID 22770.

Asynchronous notification "tcn" with payload ""tcndata",D,"a"='1","b"='2012-12-22'" received from server process with PID 22770.
```

F.59. **test_decoding**

`test_decoding` is an example of a logical decoding output plugin. It doesn't do anything especially useful, but can serve as a starting point for developing your own output plugin.

`test_decoding` receives WAL through the logical decoding mechanism and decodes it into text representations of the operations performed.
Typical output from this plugin, used over the SQL logical decoding interface, might be:

```
postgres=# SELECT * FROM pg_logical_slot_get_changes('test_slot', NULL, NULL, 'include-xids', '0');
   lsn     | xid |                       data
-----------------+-----+--------------------------------------------------
0/16D30F8 | 691 | BEGIN
0/16D32A0 | 691 | table public.data: INSERT: id[int4]:2 data[text]:'arg'
0/16D32A0 | 691 | table public.data: INSERT: id[int4]:3 data[text]:'demo'
0/16D32A0 | 691 | COMMIT
0/16D32D8 | 692 | BEGIN
0/16D3398 | 692 | table public.data: DELETE: id[int4]:2
0/16D3398 | 692 | table public.data: DELETE: id[int4]:3
0/16D3398 | 692 | COMMIT
(8 rows)
```

We can also get the changes of the in-progress transaction, and the typical output might be:

```
postgres[33712]=# SELECT * FROM pg_logical_slot_get_changes('test_slot', NULL, NULL, 'stream-changes', '1');
   lsn     | xid |                       data
-----------------+-----+--------------------------------------------------
0/16B21F8 | 503 | opening a streamed block for transaction TXN 503
0/16B21F8 | 503 | streaming change for TXN 503
0/16B2300 | 503 | streaming change for TXN 503
0/16B2408 | 503 | streaming change for TXN 503
0/16BEBA0 | 503 | closing a streamed block for transaction TXN 503
0/16B21F8 | 503 | opening a streamed block for transaction TXN 503
0/16BECA8 | 503 | streaming change for TXN 503
0/16BEDB0 | 503 | streaming change for TXN 503
0/16BEEB8 | 503 | streaming change for TXN 503
0/16BEBA0 | 503 | closing a streamed block for transaction TXN 503
```

F.60. tsm_system_rows

The `tsm_system_rows` module provides the table sampling method `SYSTEM_ROWS`, which can be used in the `TABLESAMPLE` clause of a `SELECT` command.

This table sampling method accepts a single integer argument that is the maximum number of rows to read. The resulting sample will always contain exactly that many rows, unless the table does not contain enough rows, in which case the whole table is selected.

Like the built-in `SYSTEM` sampling method, `SYSTEM_ROWS` performs block-level sampling, so that the sample is not completely random but may be subject to clustering effects, especially if only a small number of rows are requested.

`SYSTEM_ROWS` does not support the `REPEATABLE` clause.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.60.1. Examples

Here is an example of selecting a sample of a table with `SYSTEM_ROWS`. First install the extension:

```
CREATE EXTENSION tsm_system_rows;
```

Then you can use it in a `SELECT` command, for instance:

```
SELECT * FROM my_table TABLESAMPLE SYSTEM_ROWS(100);
```
This command will return a sample of 100 rows from the table my_table (unless the table does not have 100 visible rows, in which case all its rows are returned).

**F.61. tsm_system_time**

The tsm_system_time module provides the table sampling method SYSTEM_TIME, which can be used in the TABLESAMPLE clause of a SELECT command.

This table sampling method accepts a single floating-point argument that is the maximum number of milliseconds to spend reading the table. This gives you direct control over how long the query takes, at the price that the size of the sample becomes hard to predict. The resulting sample will contain as many rows as could be read in the specified time, unless the whole table has been read first.

Like the built-in SYSTEM sampling method, SYSTEM_TIME performs block-level sampling, so that the sample is not completely random but may be subject to clustering effects, especially if only a small number of rows are selected.

SYSTEM_TIME does not support the REPEATABLE clause.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

**F.61.1. Examples**

Here is an example of selecting a sample of a table with SYSTEM_TIME. First install the extension:

```
CREATE EXTENSION tsm_system_time;
```

Then you can use it in a SELECT command, for instance:

```
SELECT * FROM my_table TABLESAMPLE SYSTEM_TIME(1000);
```

This command will return as large a sample of my_table as it can read in 1 second (1000 milliseconds). Of course, if the whole table can be read in under 1 second, all its rows will be returned.

**F.62. unaccent**

unaccent is a text search dictionary that removes accents (diacritic signs) from lexemes. It’s a filtering dictionary, which means its output is always passed to the next dictionary (if any), unlike the normal behavior of dictionaries. This allows accent-insensitive processing for full text search.

The current implementation of unaccent cannot be used as a normalizing dictionary for the thesaurus dictionary.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

**F.62.1. Configuration**

An unaccent dictionary accepts the following options:

- **RULES** is the base name of the file containing the list of translation rules. This file must be stored in $$SHAREDIR/tsearch_data/$$ (where $$SHAREDIR$$ means the Postgres Pro installation’s shared-data directory). Its name must end in .rules (which is not to be included in the RULES parameter).

The rules file has the following format:

- Each line represents one translation rule, consisting of a character with accent followed by a character without accent. The first is translated into the second. For example,

  À      A
The two characters must be separated by whitespace, and any leading or trailing whitespace on a line is ignored.

- Alternatively, if only one character is given on a line, instances of that character are deleted; this is useful in languages where accents are represented by separate characters.

- Actually, each “character” can be any string not containing whitespace, so `unaccent` dictionaries could be used for other sorts of substring substitutions besides diacritic removal.

- As with other Postgres Pro text search configuration files, the rules file must be stored in UTF-8 encoding. The data is automatically translated into the current database’s encoding when loaded. Any lines containing untranslatable characters are silently ignored, so that rules files can contain rules that are not applicable in the current encoding.

A more complete example, which is directly useful for most European languages, can be found in `unaccent.rules`, which is installed in `$SHAREDIR/tsearch_data/` when the `unaccent` module is installed. This rules file translates characters with accents to the same characters without accents, and it also expands ligatures into the equivalent series of simple characters (for example, ÅE to AE).

### F.62.2. Usage

Installing the `unaccent` extension creates a text search template `unaccent` and a dictionary `unaccent` based on it. The `unaccent` dictionary has the default parameter setting `RULES='unaccent'`, which makes it immediately usable with the standard `unaccent.rules` file. If you wish, you can alter the parameter, for example:

```sql
mydb=# ALTER TEXT SEARCH DICTIONARY unaccent (RULES='my_rules');
```

or create new dictionaries based on the template.

To test the dictionary, you can try:

```sql
mydb=# select ts_lexize('unaccent','Hôtel');
```

```text
{Hotel}
(1 row)
```

Here is an example showing how to insert the `unaccent` dictionary into a text search configuration:

```sql
mydb=# CREATE TEXT SEARCH CONFIGURATION fr ( COPY = french );
mydb=# ALTER TEXT SEARCH CONFIGURATION fr
ALTER MAPPING FOR hword, hword_part, word
    WITH unaccent, french_stem;
mydb=# select to_tsvector('fr','Hôtels de la Mer');
```

```text
to_tsvector
-------------------
'hotel':1 'mer':4
(1 row)
```

```sql
mydb=# select to_tsvector('fr','Hôtel de la Mer') @@ to_tsquery('fr','Hotels');
```

```text
?column?
----------
t
(1 row)
```
mydb=# select ts_headline('fr','Hôtel de la Mer',to_tsquery('fr','Hotels'));

<table>
<thead>
<tr>
<th>ts_headline</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;b&gt;Hôtel&lt;/b&gt; de la Mer</td>
</tr>
</tbody>
</table>

(1 row)

F.62.3. Functions

The `unaccent()` function removes accents (diacritic signs) from a given string. Basically, it's a wrapper around `unaccent`-type dictionaries, but it can be used outside normal text search contexts.

```
unaccent([dictionary regdictionary, ] string text) returns text
```

If the `dictionary` argument is omitted, the text search dictionary named `unaccent` and appearing in the same schema as the `unaccent()` function itself is used.

For example:

```
SELECT unaccent('unaccent', 'Hôtel');
SELECT unaccent('Hôtel');
```

F.63. uuid-ossp

The `uuid-ossp` module provides functions to generate universally unique identifiers (UUIDs) using one of several standard algorithms. There are also functions to produce certain special UUID constants. This module is only necessary for special requirements beyond what is available in core PostgreSQL. See Section 9.14 for built-in ways to generate UUIDs.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.63.1. uuid-ossp Functions

Table F.86 shows the functions available to generate UUIDs. The relevant standards ITU-T Rec. X.667, ISO/IEC 9834-8:2005, and RFC 4122 specify four algorithms for generating UUIDs, identified by the version numbers 1, 3, 4, and 5. (There is no version 2 algorithm.) Each of these algorithms could be suitable for a different set of applications.

Table F.86. Functions for UUID Generation

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>uuid_generate_v1</code></td>
<td>() → uuid</td>
</tr>
<tr>
<td>Generates a version 1 UUID. This involves the MAC address of the computer and a time stamp. Note that UUIDs of this kind reveal the identity of the computer that created the identifier and the time at which it did so, which might make it unsuitable for certain security-sensitive applications.</td>
<td></td>
</tr>
<tr>
<td><code>uuid_generate_v1mc</code></td>
<td>() → uuid</td>
</tr>
<tr>
<td>Generates a version 1 UUID, but uses a random multicast MAC address instead of the real MAC address of the computer.</td>
<td></td>
</tr>
<tr>
<td><code>uuid_generate_v3</code></td>
<td>(namespace uuid, name text) → uuid</td>
</tr>
<tr>
<td>Generates a version 3 UUID in the given namespace using the specified input name. The namespace should be one of the special constants produced by the <code>uuid_ns_*()</code> functions shown in Table F.87. (It could be any UUID in theory.) The name is an identifier in the selected namespace.</td>
<td></td>
</tr>
<tr>
<td>For example:</td>
<td></td>
</tr>
<tr>
<td><code>SELECT uuid_generate_v3(uuid_ns_url(), 'http://www.postgresql.org');</code></td>
<td></td>
</tr>
</tbody>
</table>
### F.63.2. Building `uuid-ossp`

Historically this module depended on the OSSP UUID library, which accounts for the module's name. While the OSSP UUID library can still be found at [http://www.ossp.org/pkg/lib/uuid/](http://www.ossp.org/pkg/lib/uuid/), it is not well maintained, and is becoming increasingly difficult to port to newer platforms. `uuid-ossp` can now be built without the OSSP library on some platforms. On FreeBSD, NetBSD, and some other BSD-derived platforms, suitable UUID creation functions are included in the core `libc` library. On Linux, macOS, and some other platforms, suitable functions are provided in the `libuuid` library, which originally came from the e2fsprogs project (though on modern Linux it is considered part of `util-linux-ng`). When invoking `configure`, specify `--with-uuid=bsd` to use the BSD functions, or `--with-uuid=e2fs` to use e2fsprogs' `libuuid`, or `--with-uuid=ossp` to use the OSSP UUID library. More than one of these libraries might be available on a particular machine, so `configure` does not automatically choose one.

### F.63.3. Author

Peter Eisentraut <peter_e@gmx.net>

### F.64. xml2

The `xml2` module provides XPath querying and XSLT functionality.

### F.64.1. Deprecation Notice

From PostgreSQL 8.3 on, there is XML-related functionality based on the SQL/XML standard in the core server. That functionality covers XML syntax checking and XPath queries, which is what this module does, and more, but the API is not at all compatible. It is planned that this module will be removed in a
future version of Postgres Pro in favor of the newer standard API, so you are encouraged to try converting
your applications. If you find that some of the functionality of this module is not available in an adequate
form with the newer API, please explain your issue to <pgsql-hackers@lists.postgresql.org> so that
the deficiency can be addressed.

F.64.2. Description of Functions

Table F.88 shows the functions provided by this module. These functions provide straightforward XML
parsing and XPath queries.

Table F.88. xml2 Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xml_valid (document text) → boolean</td>
<td>Parses the given document and returns true if the document is well-formed XML. (Note: this is an alias for the standard Postgres Pro function xml_is_well_formed(). The name xml_valid() is technically incorrect since validity and well-formedness have different meanings in XML.)</td>
</tr>
<tr>
<td>xpath_string (document text, query text) → text</td>
<td>Evaluates the XPath query on the supplied document, and casts the result to text.</td>
</tr>
<tr>
<td>xpath_number (document text, query text) → real</td>
<td>Evaluates the XPath query on the supplied document, and casts the result to real.</td>
</tr>
<tr>
<td>xpath_bool (document text, query text) → boolean</td>
<td>Evaluates the XPath query on the supplied document, and casts the result to boolean.</td>
</tr>
</tbody>
</table>
| xpath_nodeset (document text, query text, toptag text, itemtag text) → text | Evaluates the query on the document and wraps the result in XML tags. If the result is multivalued, the output will look like:

  <toptag>
  <itemtag>Value 1 which could be an XML fragment</itemtag>
  <itemtag>Value 2....</itemtag>
  </toptag>

  If either toptag or itemtag is an empty string, the relevant tag is omitted. |
| xpath_nodeset (document text, query text, itemtag text) → text | Like xpath_nodeset(document, query, toptag, itemtag) but result omits toptag. |
| xpath_nodeset (document text, query text) → text | Like xpath_nodeset(document, query, toptag, itemtag) but result omits both tags. |
| xpath_list (document text, query text, separator text) → text | Evaluates the query on the document and returns multiple values separated by the specified separator, for example Value 1,Value 2,Value 3 if separator is , . |
| xpath_list (document text, query text) → text | This is a wrapper for the above function that uses , as the separator. |

F.64.3. xpath_table

xpath_table(text key, text document, text relation, text xpaths, text criteria) returns setof record

xpath_table is a table function that evaluates a set of XPath queries on each of a set of documents and
returns the results as a table. The primary key field from the original document table is returned as the first column of the result so that the result set can readily be used in joins. The parameters are described in Table F.89.
Table F.89. xpath_table Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>key</td>
<td>the name of the “key” field — this is just a field to be used as the first column of the output table, i.e., it identifies the record from which each output row came (see note below about multiple values)</td>
</tr>
<tr>
<td>document</td>
<td>the name of the field containing the XML document</td>
</tr>
<tr>
<td>relation</td>
<td>the name of the table or view containing the documents</td>
</tr>
<tr>
<td>xpaths</td>
<td>one or more XPath expressions, separated by</td>
</tr>
<tr>
<td>criteria</td>
<td>the contents of the WHERE clause. This cannot be omitted, so use true or 1=1 if you want to process all the rows in the relation</td>
</tr>
</tbody>
</table>

These parameters (except the XPath strings) are just substituted into a plain SQL SELECT statement, so you have some flexibility — the statement is

```sql
SELECT <key>, <document> FROM <relation> WHERE <criteria>
```

so those parameters can be anything valid in those particular locations. The result from this SELECT needs to return exactly two columns (which it will unless you try to list multiple fields for key or document). Beware that this simplistic approach requires that you validate any user-supplied values to avoid SQL injection attacks.

The function has to be used in a FROM expression, with an AS clause to specify the output columns; for example

```sql
SELECT * FROM
xpath_table('article_id',
  'article_xml',
  'articles',
  '/article/author|/article/pages|/article/title',
  'date_entered > ''2003-01-01'' ')
AS t(article_id integer, author text, page_count integer, title text);
```

The AS clause defines the names and types of the columns in the output table. The first is the “key” field and the rest correspond to the XPath queries. If there are more XPath queries than result columns, the extra queries will be ignored. If there are more result columns than XPath queries, the extra columns will be NULL.

Notice that this example defines the page_count result column as an integer. The function deals internally with string representations, so when you say you want an integer in the output, it will take the string representation of the XPath result and use Postgres Pro input functions to transform it into an integer (or whatever type the AS clause requests). An error will result if it can't do this — for example if the result is empty — so you may wish to just stick to text as the column type if you think your data has any problems.

The calling SELECT statement doesn't necessarily have to be just SELECT * — it can reference the output columns by name or join them to other tables. The function produces a virtual table with which you can perform any operation you wish (e.g., aggregation, joining, sorting etc). So we could also have:

```sql
SELECT t.title, p.fullname, p.email
FROM xpath_table('article_id', 'article_xml', 'articles',
  '/article/title|/article/author/@id',
  'xpath_string(article_xml,"'/article/@date'") > ''2003-03-20'' ')
AS t(article_id integer, title text, author_id integer),
  tblPeopleInfo AS p
WHERE t.author_id = p.person_id;
```

as a more complicated example. Of course, you could wrap all of this in a view for convenience.
F.64.3.1. Multivalued Results

The xpath_table function assumes that the results of each XPath query might be multivalued, so the number of rows returned by the function may not be the same as the number of input documents. The first row returned contains the first result from each query, the second row the second result from each query. If one of the queries has fewer values than the others, null values will be returned instead.

In some cases, a user will know that a given XPath query will return only a single result (perhaps a unique document identifier) — if used alongside an XPath query returning multiple results, the single-valued result will appear only on the first row of the result. The solution to this is to use the key field as part of a join against a simpler XPath query. As an example:

```sql
CREATE TABLE test (id int PRIMARY KEY, xml text);
INSERT INTO test VALUES (1, '<doc num="C1"> <line num="L1"> <a>1</a> <b>2</b> <c>3</c> </line> <line num="L2"> <a>11</a> <b>22</b> <c>33</c> </line> </doc>');
INSERT INTO test VALUES (2, '<doc num="C2"> <line num="L1"> <a>111</a> <b>222</b> <c>333</c> </line> <line num="L2"> <a>111</a> <b>222</b> <c>333</c> </line> </doc>');
SELECT * FROM xpath_table('id','xml','test', '/doc/@num|/doc/line/@num|/doc/line/a|/doc/line/b|/doc/line/c', 'true') AS t(id int, doc_num varchar(10), line_num varchar(10), val1 int, val2 int, val3 int) WHERE id = 1 ORDER BY doc_num, line_num
```

```
<table>
<thead>
<tr>
<th>id</th>
<th>doc_num</th>
<th>line_num</th>
<th>val1</th>
<th>val2</th>
<th>val3</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>C1</td>
<td>L1</td>
<td>1</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td></td>
<td></td>
<td>L2</td>
<td>11</td>
<td>22</td>
<td>33</td>
</tr>
</tbody>
</table>
```

To get `doc_num` on every line, the solution is to use two invocations of `xpath_table` and join the results:

```sql
SELECT t.*, i.doc_num FROM xpath_table('id', 'xml', 'test', '/doc/line/@num|/doc/line/a|/doc/line/b|/doc/line/c', 'true') AS t(id int, line_num varchar(10), val1 int, val2 int, val3 int), xpath_table('id', 'xml', 'test', '/doc/@num', 'true') AS i(id int, doc_num varchar(10)) WHERE i.id=t.id AND i.id=1 ORDER BY doc_num, line_num;
```

```
<table>
<thead>
<tr>
<th>id</th>
<th>line_num</th>
<th>val1</th>
<th>val2</th>
<th>val3</th>
<th>doc_num</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>L1</td>
<td>1</td>
<td>2</td>
<td>3</td>
<td>C1</td>
</tr>
<tr>
<td>1</td>
<td>L2</td>
<td>11</td>
<td>22</td>
<td>33</td>
<td>C1</td>
</tr>
</tbody>
</table>
```

F.64.4. XSLT Functions

The following functions are available if libxslt is installed:
**F.64.4.1. xslt_process**

\texttt{xslt_process(text document, text stylesheet, text paramlist) returns text}

This function applies the XSL stylesheet to the document and returns the transformed result. The \texttt{paramlist} is a list of parameter assignments to be used in the transformation, specified in the form \texttt{a=1,b=2}. Note that the parameter parsing is very simple-minded: parameter values cannot contain commas!

There is also a two-parameter version of \texttt{xslt_process} which does not pass any parameters to the transformation.

**F.64.5. Author**

\textbf{John Gray} <jgray@azuli.co.uk>

Development of this module was sponsored by Torchbox Ltd. (www.torchbox.com). It has the same BSD license as Postgres Pro.
Appendix G. Additional Supplied Programs

This appendix and the previous one contain information regarding additional modules available in the Postgres Pro Standard distribution. See Appendix F for more information about the server extensions and plug-ins.

This appendix covers the utility programs. Once installed, they are found in the `bin` directory of the Postgres Pro Standard installation and can be used like any other program.

G.1. Client Applications

This section covers Postgres Pro Standard client applications. They can be run from anywhere, independent of where the database server resides. See also Postgres Pro Client Applications for information about client applications that are part of the core Postgres Pro Standard distribution.
oid2name

oid2name — resolve OIDs and file nodes in a Postgres Pro data directory

Synopsis

oid2name [option...]

Description

oid2name is a utility program that helps administrators to examine the file structure used by Postgres Pro. To make use of it, you need to be familiar with the database file structure, which is described in Chapter 66.

Note

The name “oid2name” is historical, and is actually rather misleading, since most of the time when you use it, you will really be concerned with tables' filenode numbers (which are the file names visible in the database directories). Be sure you understand the difference between table OIDs and table filenodes!

oid2name connects to a target database and extracts OID, filenode, and/or table name information. You can also have it show database OIDs or tablespace OIDs.

Options

oid2name accepts the following command-line arguments:

- `-f filenode`
  `--filenode=filenode`
  show info for table with filenode filenode.

- `-i`
  `--indexes`
  include indexes and sequences in the listing.

- `-o oid`
  `--oid=oid`
  show info for table with OID oid.

- `-q`
  `--quiet`
  omit headers (useful for scripting).

- `-s`
  `--tablespaces`
  show tablespace OIDs.

- `-S`
  `--system-objects`
  include system objects (those in information_schema, pg_toast and pg_catalog schemas).

- `-t tablename_pattern`
  `--table=tablename_pattern`
  show info for table(s) matching tablename_pattern.
Additional Supplied Programs

-V
--version

Print the oid2name version and exit.

-x
--extended

display more information about each object shown: tablespace name, schema name, and OID.

-?
--help

Show help about oid2name command line arguments, and exit.

oid2name also accepts the following command-line arguments for connection parameters:

-d database
--dbname=database

database to connect to.

-h host
--host=host

database server's host.

-H host

database server's host. Use of this parameter is deprecated as of Postgres Pro 12.

-p port
--port=port

database server's port.

-U username
--username=username

user name to connect as.

To display specific tables, select which tables to show by using -o, -f and/or -t. -o takes an OID, -f takes a filenode, and -t takes a table name (actually, it's a LIKE pattern, so you can use things like foo %). You can use as many of these options as you like, and the listing will include all objects matched by any of the options. But note that these options can only show objects in the database given by -d.

If you don't give any of -o, -f or -t, but do give -d, it will list all tables in the database named by -d. In this mode, the -S and -i options control what gets listed.

If you don't give -d either, it will show a listing of database OIDs. Alternatively you can give -s to get a tablespace listing.

Environment

PGHOST
PGPORT
PGUSER

Default connection parameters.

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by libpq (see Section 32.15).

The environment variable PG_COLOR specifies whether to use color in diagnostic messages. Possible values are always, auto and never.
Notes

oid2name requires a running database server with non-corrupt system catalogs. It is therefore of only limited use for recovering from catastrophic database corruption situations.

Examples

$ # what's in this database server, anyway?

Description

pg_probackup is a utility to manage backup and recovery of Postgres Pro database clusters. It is designed to perform periodic backups of the Postgres Pro instance that enable you to restore the server in case of a failure. pg_probackup supports PostgreSQL 9.5 or higher.

- Overview
- Installation and Setup
- Command-Line Reference
- Usage

Overview

As compared to other backup solutions, pg_probackup offers the following benefits that can help you implement different backup strategies and deal with large amounts of data:
Additional Supplied Programs

- Incremental backup: with three different incremental modes, you can plan the backup strategy in accordance with your data flow. Incremental backups allow you to save disk space and speed up backup as compared to taking full backups. It is also faster to restore the cluster by applying incremental backups than by replaying WAL files.
- Incremental restore: speed up restore from backup by reusing valid unchanged pages available in PGDATA.
- Validation: automatic data consistency checks and on-demand backup validation without actual data recovery.
- Verification: on-demand verification of Postgres Pro instance with the checkdb command.
- Retention: managing WAL archive and backups in accordance with retention policy. You can configure retention policy based on recovery time or the number of backups to keep, as well as specify time to live (TTL) for a particular backup. Expired backups can be merged or deleted.
- Parallelization: running backup, restore, merge, delete, validate, and checkdb processes on multiple parallel threads.
- Compression: storing backup data in a compressed state to save disk space.
- Deduplication: saving disk space by excluding non-data files (such as _vm or _fsm) from incremental backups if these files have not changed since they were copied into one of the previous backups in this incremental chain.
- Remote operations: backing up Postgres Pro instance located on a remote system or restoring a backup remotely.
- Backup from standby: avoiding extra load on master by taking backups from a standby server.
- External directories: backing up files and directories located outside of the Postgres Pro data directory (PGDATA), such as scripts, configuration files, logs, or SQL dump files.
- Backup catalog: getting the list of backups and the corresponding meta information in plain text or JSON formats.
- Archive catalog: getting the list of all WAL timelines and the corresponding meta information in plain text or JSON formats.
- Partial restore: restoring only the specified databases.
- Catchup: cloning a Postgres Pro instance for a fallen-behind standby server to “catch up” with master.

To manage backup data, pg_probackup creates a backup catalog. This is a directory that stores all backup files with additional meta information, as well as WAL archives required for point-in-time recovery. You can store backups for different instances in separate subdirectories of a single backup catalog.

Using pg_probackup, you can take full or incremental backups:

- FULL backups contain all the data files required to restore the database cluster.
- Incremental backups operate at the page level, only storing the data that has changed since the previous backup. It allows you to save disk space and speed up the backup process as compared to taking full backups. It is also faster to restore the cluster by applying incremental backups than by replaying WAL files. pg_probackup supports the following modes of incremental backups:
  - DELTA backup. In this mode, pg_probackup reads all data files in the data directory and copies only those pages that have changed since the previous backup. This mode can impose read-only I/O pressure equal to a full backup.
  - PAGE backup. In this mode, pg_probackup scans all WAL files in the archive from the moment the previous full or incremental backup was taken. Newly created backups contain only the pages that were mentioned in WAL records. This requires all the WAL files since the previous backup to be present in the WAL archive. If the size of these files is comparable to the total size of the database cluster files, speedup is smaller, but the backup still takes less space. You have to configure WAL archiving as explained in Setting up continuous WAL archiving to make PAGE backups.
  - PTRACK backup. In this mode, Postgres Pro tracks page changes on the fly. Continuous archiving is not necessary for it to operate. Each time a relation page is updated, this page is marked in a special PTRACK bitmap. Tracking implies some minor overhead on the database server operation, but speeds up incremental backups significantly.
pg_probackup can take only physical online backups, and online backups require WAL for consistent recovery. So regardless of the chosen backup mode (FULL, PAGE or DELTA), any backup taken with pg_probackup must use one of the following WAL delivery modes:

- **ARCHIVE.** Such backups rely on continuous archiving to ensure consistent recovery. This is the default WAL delivery mode.
- **STREAM.** Such backups include all the files required to restore the cluster to a consistent state at the time the backup was taken. Regardless of continuous archiving having been set up or not, the WAL segments required for consistent recovery are streamed via replication protocol during backup and included into the backup files. That's why such backups are called autonomous, or standalone.

**Limitations**

pg_probackup currently has the following limitations:

- pg_probackup only supports PostgreSQL 9.5 and higher.
- The remote mode is not supported on Windows systems.
- On Unix systems, for Postgres Pro 10 or lower, a backup can be made only by the same OS user that has started the Postgres Pro server. For example, if Postgres Pro server is started by user postgres, the backup command must also be run by user postgres. To satisfy this requirement when taking backups in the remote mode using SSH, you must set --remote-user option to postgres.
- For Postgres Pro 9.5, functions pg_create_restore_point(text) and pg_switch_xlog() can be executed only if the backup role is a superuser, so backup of a cluster with low amount of WAL traffic by a non-superuser role can take longer than the backup of the same cluster by a superuser role.
- The Postgres Pro server from which the backup was taken and the restored server must be compatible by the block_size and wal_block_size parameters and have the same major release number. Depending on cluster configuration, Postgres Pro itself may apply additional restrictions, such as CPU architecture or libc/libicu versions.

**Installation and Setup**

Once you have pg_probackup installed, complete the following setup:

- Initialize the backup catalog.
- Add a new backup instance to the backup catalog.
- Configure the database cluster to enable pg_probackup backups.
- Optionally, configure SSH for running pg_probackup operations in the remote mode.

**Initializing the Backup Catalog**

pg_probackup stores all WAL and backup files in the corresponding subdirectories of the backup catalog. To initialize the backup catalog, run the following command:

```
pg_probackup init -B backup_dir
```

where `backup_dir` is the path to the backup catalog. If the `backup_dir` already exists, it must be empty. Otherwise, pg_probackup returns an error.

The user launching pg_probackup must have full access to the `backup_dir` directory.

pg_probackup creates the `backup_dir` backup catalog, with the following subdirectories:

- `wal/` — directory for WAL files.
- `backups/` — directory for backup files.

Once the backup catalog is initialized, you can add a new backup instance.
Adding a New Backup Instance

pg_probackup can store backups for multiple database clusters in a single backup catalog. To set up the required subdirectories, you must add a backup instance to the backup catalog for each database cluster you are going to back up.

To add a new backup instance, run the following command:

```bash
pg_probackup add-instance -B backup_dir -D data_dir --instance instance_name
[remote_options]
```

where:

- `data_dir` is the data directory of the cluster you are going to back up. To set up and use pg_probackup, write access to this directory is required.
- `instance_name` is the name of the subdirectories that will store WAL and backup files for this cluster.
- `remote_options` are optional parameters that need to be specified only if `data_dir` is located on a remote system.

pg_probackup creates the `instance_name` subdirectories under the `backups/` and `wal/` directories of the backup catalog. The `backups/instance_name` directory contains the `pg_probackup.conf` configuration file that controls pg_probackup settings for this backup instance. If you run this command with the `remote_options`, the specified parameters will be added to `pg_probackup.conf`.

For details on how to fine-tune pg_probackup configuration, see the section called “Configuring pg_probackup”.

The user launching pg_probackup must have full access to `backup_dir` directory and at least read-only access to `data_dir` directory. If you specify the path to the backup catalog in the `BACKUP_PATH` environment variable, you can omit the corresponding option when running pg_probackup commands.

**Note**

For Postgres Pro 11 or higher, it is recommended to use the `group access` feature, so that backup can be done by any OS user in the same group as the cluster owner. In this case, the user should have read permissions for the cluster directory.

Configuring the Database Cluster

Although pg_probackup can be used by a superuser, it is recommended to create a separate role with the minimum permissions required for the chosen backup strategy. In these configuration instructions, the `backup` role is used as an example.

To perform a backup, the following permissions for role `backup` are required only in the database **used for connection** to the Postgres Pro server:

For Postgres Pro 9.5:

```sql
BEGIN;
CREATE ROLE backup WITH LOGIN;
GRANT USAGE ON SCHEMA pg_catalog TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.current_setting(text) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.set_config(text, text, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_is_in_recovery() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_start_backup(text, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_stop_backup() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_create_restore_point(text) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current() TO backup;
```
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current_snapshot() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_snapshot_xmax(txid_snapshot) TO backup;
COMMIT;

For Postgres Pro 9.6:

BEGIN;
CREATE ROLE backup WITH LOGIN;
GRANT USAGE ON SCHEMA pg_catalog TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.current_setting(text) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.set_config(text, text, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_is_in_recovery() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_start_backup(text, boolean, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_stop_backup(boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_create_restore_point(text) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_switch_xlog() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_last_xlog_replay_location() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current_snapshot() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_snapshot_xmax(txid_snapshot) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_control_checkpoint() TO backup;
COMMIT;

For Postgres Pro 10 or higher:

BEGIN;
CREATE ROLE backup WITH LOGIN;
GRANT USAGE ON SCHEMA pg_catalog TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.current_setting(text) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.set_config(text, text, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_is_in_recovery() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_start_backup(text, boolean, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_stop_backup(boolean, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_create_restore_point(text) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_switch_wal() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_last_wal_replay_lsn() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_snapshot_xmax(txid_snapshot) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_control_checkpoint() TO backup;
COMMIT;

In the pg_hba.conf file, allow connection to the database cluster on behalf of the backup role.

Since pg_probackup needs to read cluster files directly, pg_probackup must be started by (or connected to, if used in the remote mode) the OS user that has read access to all files and directories inside the data directory (PGDATA) you are going to back up.

Depending on whether you plan to take standalone or archive backups, Postgres Pro cluster configuration will differ, as specified in the sections below. To back up the database cluster from a standby server, run pg_probackup in the remote mode, or create PTRACK backups, additional setup is required.

For details, see the sections Setting up STREAM Backups, Setting up continuous WAL archiving, Setting up Backup from Standby, Configuring the Remote Mode, Setting up Partial Restore, and Setting up PTRACK Backups.

**Setting up STREAM Backups**

To set up the cluster for STREAM backups, complete the following steps:

- Grant the REPLICATION privilege to the backup role:
ALTER ROLE backup WITH REPLICATION;

• In the pg_hba.conf file, allow replication on behalf of the backup role.
• Make sure the parameter max_wal_senders is set high enough to leave at least one session available for the backup process.
• Set the parameter wal_level to be higher than minimal.

If you are planning to take PAGE backups in the STREAM mode or perform PITR with STREAM backups, you still have to configure WAL archiving, as explained in the section Setting up continuous WAL archiving.

Once these steps are complete, you can start taking FULL, PAGE, DELTA, and PTRACK backups in the STREAM WAL mode.

Note

If you are planning to rely on .pgpass for authentication when running backup in STREAM mode, then .pgpass must contain credentials for replication database, used to establish connection via replication protocol. Example: pghost:5432:replication:backup_user:my_strong_password

Setting up Continuous WAL Archiving

Making backups in PAGE backup mode, performing PITR and making backups with ARCHIVE WAL delivery mode require continuous WAL archiving to be enabled. To set up continuous archiving in the cluster, complete the following steps:

• Make sure the wal_level parameter is higher than minimal.
• If you are configuring archiving on master, archive_mode must be set to on or always. To perform archiving on standby, set this parameter to always.
• Set the archive_command parameter, as follows:

  archive_command = '"install_dir/pg_probackup" archive-push -B "backup_dir" --instance instance_name --wal-file-name=%f [remote_options]"

where install_dir is the installation directory of the pg_probackup version you are going to use, backup_dir and instance_name refer to the already initialized backup catalog instance for this database cluster, and remote_options only need to be specified to archive WAL on a remote host. For details about all possible archive-push parameters, see the section archive-push.

Once these steps are complete, you can start making backups in the ARCHIVE WAL mode, backups in the PAGE backup mode, as well as perform PITR.

You can view the current state of the WAL archive using the show command. For details, see the section called "Viewing WAL Archive Information".

If you are planning to make PAGE backups and/or backups with ARCHIVE WAL mode from a standby server that generates a small amount of WAL traffic, without long waiting for WAL segment to fill up, consider setting the archive_timeout Postgres Pro parameter on master. The value of this parameter should be slightly lower than the --archive-timeout setting (5 minutes by default), so that there is enough time for the rotated segment to be streamed to standby and sent to WAL archive before the backup is aborted because of --archive-timeout.

Note

Instead of using the archive-push command provided by pg_probackup, you can use any other tool to set up continuous archiving as long as it delivers WAL segments into backup_dir/wal/
instance_name directory. If compression is used, it should be gzip, and .gz suffix in filename is mandatory.

Note

Instead of configuring continuous archiving by setting the archive_mode and archive_command parameters, you can opt for using the pg_receivewal utility. In this case, pg_receivewal - D directory option should point to backup_dir/wal/instance_name directory. pg_probackup supports WAL compression that can be done by pg_receivewal. “Zero Data Loss” archive strategy can be achieved only by using pg_receivewal.

Setting up Backup from Standby

For Postgres Pro 9.6 or higher, pg_probackup can take backups from a standby server. This requires the following additional setup:

- On the standby server, set the hot_standby parameter to on.
- On the master server, set the full_page_writes parameter to on.
- To perform standalone backups on standby, complete all steps in section Setting up STREAM Backups.
- To perform archive backups on standby, complete all steps in section Setting up continuous WAL archiving.

Once these steps are complete, you can start taking FULL, PAGE, DELTA, or PTRACK backups with appropriate WAL delivery mode: ARCHIVE or STREAM, from the standby server.

Backup from the standby server has the following limitations:

- If the standby is promoted to the master during backup, the backup fails.
- All WAL records required for the backup must contain sufficient full-page writes. This requires you to enable full_page_writes on the master, and not to use tools like pg_compresslog as archive_command to remove full-page writes from WAL files.

Setting up Cluster Verification

Logical verification of a database cluster requires the following additional setup. Role backup is used as an example:

- Install the amcheck or amcheck_next extension in every database of the cluster:

  CREATE EXTENSION amcheck;

- Grant the following permissions to the backup role in every database of the cluster:

  GRANT SELECT ON TABLE pg_catalog.pg_am TO backup;
  GRANT SELECT ON TABLE pg_catalog.pg_class TO backup;
  GRANT SELECT ON TABLE pg_catalog.pg_database TO backup;
  GRANT SELECT ON TABLE pg_catalog.pg_namespace TO backup;
  GRANT SELECT ON TABLE pg_catalog.pg_extension TO backup;
  GRANT EXECUTE ON FUNCTION bt_index_check(regclass) TO backup;
  GRANT EXECUTE ON FUNCTION bt_index_check(regclass, bool) TO backup;

Setting up Partial Restore

If you are planning to use partial restore, complete the following additional step:

- Grant the read-only access to pg_catalog.pg_database to the backup role only in the database used for connection to Postgres Pro server:
Configuring the Remote Mode

pg_probackup supports the remote mode that allows to perform backup, restore and WAL archiving operations remotely. In this mode, the backup catalog is stored on a local system, while Postgres Pro instance to backup and/or to restore is located on a remote system. Currently the only supported remote protocol is SSH.

Set up SSH

If you are going to use pg_probackup in remote mode via SSH, complete the following steps:

- Install pg_probackup on both systems: backup_host and db_host.
- For communication between the hosts set up the passwordless SSH connection between backup user on backup_host and postgres user on db_host:
  ```
  [backup@backup_host] ssh-copy-id postgres@db_host
  ```
- If you are going to rely on continuous WAL archiving, set up passwordless SSH connection between postgres user on db_host and backup user on backup_host:
  ```
  [postgres@db_host] ssh-copy-id backup@backup_host
  ```

where:

- backup_host is the system with backup catalog.
- db_host is the system with Postgres Pro cluster.
- backup is the OS user on backup_host used to run pg_probackup.
- postgres is the OS user on db_host used to start the Postgres Pro cluster. For Postgres Pro 11 or higher a more secure approach can be used thanks to group access feature.

pg_probackup in the remote mode via SSH works as follows:

- Only the following commands can be launched in the remote mode: add-instance, backup, restore, catchup, archive-push, and archive-get.
- Operating in remote mode requires pg_probackup binary to be installed on both local and remote systems. The versions of local and remote binary must be the same.
- When started in the remote mode, the main pg_probackup process on the local system connects to the remote system via SSH and launches one or more agent processes on the remote system, which are called remote agents. The number of remote agents is equal to the -j/--threads setting.
- The main process uses remote agents to access remote files and transfer data between local and remote systems.
- Remote agents try to minimize the network traffic and the number of round-trips between hosts.
- The main process is usually started on backup_host and connects to db_host, but in case of archive-push and archive-get commands the main process is started on db_host and connects to backup_host.
- Once data transfer is complete, remote agents are terminated and SSH connections are closed.
- If an error condition is encountered by a remote agent, then all agents are terminated and error details are reported by the main pg_probackup process, which exits with an error.
- Compression is always done on db_host, while decompression is always done on backup_host.

Note

You can impose additional restrictions on SSH settings to protect the system in the event of account compromise.
Setting up PTRACK Backups

Note
PTRACK versions lower than 2.0 are deprecated and not supported. Postgres Pro Standard and Postgres Pro Enterprise versions starting with 11.9.1 contain PTRACK 2.0. Upgrade your server to avoid issues in backups that you will take in future and be sure to take fresh backups of your clusters with the upgraded PTRACK since the backups taken with PTRACK 1.x might be corrupt.

If you are going to use PTRACK backups, complete the following additional steps. The role that will perform PTRACK backups (the backup role in the examples below) must have access to all the databases of the cluster.

For Postgres Pro 11 or higher:
1. Create PTRACK extension:
   ```
   CREATE EXTENSION ptrack;
   ```
2. To enable tracking page updates, set `ptrack.map_size` parameter to a positive integer and restart the server.

   For optimal performance, it is recommended to set `ptrack.map_size` to \( N / 1024 \), where \( N \) is the size of the Postgres Pro cluster, in MB. If you set this parameter to a lower value, PTRACK is more likely to map several blocks together, which leads to false-positive results when tracking changed blocks and increases the incremental backup size as unchanged blocks can also be copied into the incremental backup. Setting `ptrack.map_size` to a higher value does not affect PTRACK operation, but it is not recommended to set this parameter to a value higher than 1024.

Note
If you change the `ptrack.map_size` parameter value, the previously created PTRACK map file is cleared, and tracking newly changed blocks starts from scratch. Thus, you have to retake a full backup before taking incremental PTRACK backups after changing `ptrack.map_size`.

Usage

Creating a Backup
To create a backup, run the following command:

```bash
pg_probackup backup -B backup_dir --instance instance_name -b backup_mode
```

Where `backup_mode` can take one of the following values:

- **FULL** — creates a full backup that contains all the data files of the cluster to be restored.
- **DELTA** — reads all data files in the data directory and creates an incremental backup for pages that have changed since the previous backup.
- **PAGE** — creates an incremental backup based on the WAL files that have been generated since the previous full or incremental backup was taken. Only changed blocks are read from data files.
- **PTRACK** — creates an incremental backup tracking page changes on the fly.

When restoring a cluster from an incremental backup, pg_probackup relies on the parent full backup and all the incremental backups between them, which is called “the backup chain”. You must create at least one full backup before taking incremental ones.

ARCHIVE Mode
ARCHIVE is the default WAL delivery mode.
For example, to make a FULL backup in ARCHIVE mode, run:

```
pg_probackup backup -B backup_dir --instance instance_name -b FULL
```

ARCHIVE backups rely on continuous archiving to get WAL segments required to restore the cluster to a consistent state at the time the backup was taken.

When a backup is taken, `pg_probackup` ensures that WAL files containing WAL records between `Start LSN` and `Stop LSN` actually exist in `backup_dir/wal/instance_name` directory. `pg_probackup` also ensures that WAL records between `Start LSN` and `Stop LSN` can be parsed. This precaution eliminates the risk of silent WAL corruption.

**STREAM Mode**

STREAM is the optional WAL delivery mode.

For example, to make a FULL backup in the STREAM mode, add the `--stream` flag to the command from the previous example:

```
pg_probackup backup -B backup_dir --instance instance_name -b FULL --stream --temp-slot
```

The optional `--temp-slot` flag ensures that the required segments remain available if the WAL is rotated before the backup is complete.

Unlike backups in ARCHIVE mode, STREAM backups include all the WAL segments required to restore the cluster to a consistent state at the time the backup was taken.

During backup `pg_probackup` streams WAL files containing WAL records between `Start LSN` and `Stop LSN` to `backup_dir/backups/instance_name/backup_id/database/pg_wal` directory. To eliminate the risk of silent WAL corruption, `pg_probackup` also checks that WAL records between `Start LSN` and `Stop LSN` can be parsed.

Even if you are using continuous archiving, STREAM backups can still be useful in the following cases:

- STREAM backups can be restored on the server that has no file access to WAL archive.
- STREAM backups enable you to restore the cluster state at the point in time for which WAL files in archive are no longer available.
- Backup in STREAM mode can be taken from a standby of a server that generates small amount of WAL traffic, without long waiting for WAL segment to fill up.

**Page Validation**

If data checksums are enabled in the database cluster, `pg_probackup` uses this information to check correctness of data files during backup. While reading each page, `pg_probackup` checks whether the calculated checksum coincides with the checksum stored in the page header. This guarantees that the Postgres Pro instance and the backup itself have no corrupt pages. Note that `pg_probackup` reads database files directly from the filesystem, so under heavy write load during backup it can show false-positive checksum mismatches because of partial writes. If a page checksum mismatch occurs, the page is re-read and checksum comparison is repeated.

A page is considered corrupt if checksum comparison has failed more than 100 times. In this case, the backup is aborted.

Even if data checksums are not enabled, `pg_probackup` always performs sanity checks for page headers.

**External Directories**

To back up a directory located outside of the data directory, use the optional `--external-dirs` parameter that specifies the path to this directory. If you would like to add more than one external directory, you can provide several paths separated by colons on Linux systems or semicolons on Windows systems.

For example, to include `/etc/dir1` and `/etc/dir2` directories into the full backup of your `instance_name` instance that will be stored under the `backup_dir` directory on Linux, run:  

```
pg_probackup backup -B backup_dir --instance instance_name --external-dirs /etc/dir1:/etc/dir2
```
Additional Supplied Programs

pg_probackup backup -B backup_dir --instance instance_name -b FULL --external-dirs=/etc/dir1:/etc/dir2

Similarly, to include C:\dir1 and C:\dir2 directories into the full backup on Windows, run:

pg_probackup backup -B backup_dir --instance instance_name -b FULL --external-dirs=C:\dir1;C:\dir2

pg_probackup recursively copies the contents of each external directory into a separate subdirectory in the backup catalog. Since external directories included into different backups do not have to be the same, when you are restoring the cluster from an incremental backup, only those directories that belong to this particular backup will be restored. Any external directories stored in the previous backups will be ignored.

To include the same directories into each backup of your instance, you can specify them in the pg_probackup.conf configuration file using the set-config command with the --external-dirs option.

Performing Cluster Verification

To verify that Postgres Pro database cluster is not corrupt, run the following command:

pg_probackup checkdb [-B backup_dir [--instance instance_name]] [-D data_dir] [connection_options]

This command performs physical verification of all data files located in the specified data directory by running page header sanity checks, as well as block-level checksum verification if checksums are enabled. If a corrupt page is detected, checkdb continues cluster verification until all pages in the cluster are validated.

By default, similar page validation is performed automatically while a backup is taken by pg_probackup. The checkdb command enables you to perform such page validation on demand, without taking any backup copies, even if the cluster is not backed up using pg_probackup at all.

To perform cluster verification, pg_probackup needs to connect to the cluster to be verified. In general, it is enough to specify the backup instance of this cluster for pg_probackup to determine the required connection options. However, if -B and --instance options are omitted, you have to provide connection options and data_dir via environment variables or command-line options.

Physical verification cannot detect logical inconsistencies, missing or nullified blocks and entire files, or similar anomalies. Extensions amcheck and amcheck_next provide a partial solution to these problems.

If you would like, in addition to physical verification, to verify all indexes in all databases using these extensions, you can specify the --amcheck flag when running the checkdb command:

pg_probackup checkdb -D data_dir --amcheck [connection_options]

You can skip physical verification by specifying the --skip-block-validation flag. In this case, you can omit backup_dir and data_dir options, only connection options are mandatory:

pg_probackup checkdb --amcheck --skip-block-validation [connection_options]

Logical verification can be done more thoroughly with the --heapallindexed flag by checking that all heap tuples that should be indexed are actually indexed, but at the higher cost of CPU, memory, and I/O consumption.

Validating a Backup

pg_probackup calculates checksums for each file in a backup during the backup process. The process of checking checksums of backup data files is called the backup validation. By default, validation is run immediately after the backup is taken and right before the restore, to detect possible backup corruption.

If you would like to skip backup validation, you can specify the --no-validate flag when running backup and restore commands.
To ensure that all the required backup files are present and can be used to restore the database cluster, you can run the `validate` command with the exact `recovery target options` you are going to use for recovery.

For example, to check that you can restore the database cluster from a backup copy up to transaction ID 4242, run this command:

```
pg_probackup validate -B backup_dir --instance instance_name --recovery-target-xid=4242
```

If validation completes successfully, `pg_probackup` displays the corresponding message. If validation fails, you will receive an error message with the exact time, transaction ID, and LSN up to which the recovery is possible.

If you specify `backup_id` via `-i/--backup-id` option, then only the backup copy with specified backup ID will be validated. If `backup_id` is specified with `recovery target options`, the `validate` command will check whether it is possible to restore the specified backup to the specified recovery target.

For example, to check that you can restore the database cluster from a backup copy with the PT8XFX backup ID up to the specified timestamp, run this command:

```
pg_probackup validate -B backup_dir --instance instance_name -i PT8XFX --recovery-target-time="2017-05-18 14:18:11+03"
```

If you specify the `backup_id` of an incremental backup, all its parents starting from FULL backup will be validated.

If you omit all the parameters, all backups are validated.

**Restoring a Cluster**

To restore the database cluster from a backup, run the `restore` command with at least the following options:

```
pg_probackup restore -B backup_dir --instance instance_name -i backup_id
```

where:

- `backup_dir` is the backup catalog that stores all backup files and meta information.
- `instance_name` is the backup instance for the cluster to be restored.
- `backup_id` specifies the backup to restore the cluster from. If you omit this option, `pg_probackup` uses the latest valid backup available for the specified instance. If you specify an incremental backup to restore, `pg_probackup` automatically restores the underlying full backup and then sequentially applies all the necessary increments.

Once the `restore` command is complete, start the database service.

If you restore `ARCHIVE` backups, perform `PITR`, or specify the `--restore-as-replica` flag with the `restore` command to set up a standby server, `pg_probackup` creates a recovery configuration file once all data files are copied into the target directory. This file includes the minimal settings required for recovery, except for the password in the `primary_conninfo` parameter; you have to add the password manually or use the `--primary-conninfo` option, if required. For Postgres Pro 11 or lower, recovery settings are written into the `recovery.conf` file. Starting from Postgres Pro 12, `pg_probackup` writes these settings into the `probackup_recovery.conf` file and then includes it into `postgresql.auto.conf`.

If you are restoring a `STREAM` backup, the restore is complete at once, with the cluster returned to a self-consistent state at the point when the backup was taken. For `ARCHIVE` backups, Postgres Pro replays all available archived WAL segments, so the cluster is restored to the latest state possible within the current timeline. You can change this behavior by using the `recovery target options` with the `restore` command, as explained in the section called "Performing Point-in-Time (PITR) Recovery".

If the cluster to restore contains tablespaces, `pg_probackup` restores them to their original location by default. To restore tablespaces to a different location, use the `--tablespace-mapping/-T` option.
Otherwise, restoring the cluster on the same host will fail if tablespaces are in use, because the backup would have to be written to the same directories.

When using the `--tablespace-mapping/-T` option, you must provide absolute paths to the old and new tablespace directories. If a path happens to contain an equals sign (=), escape it with a backslash. This option can be specified multiple times for multiple tablespaces. For example:

```
pg_probackup restore -B backup_dir --instance instance_name -D data_dir -j 4 -i backup_id -T tablespace1_dir=tablespace1_newdir -T tablespace2_dir=tablespace2_newdir
```

To restore the cluster on a remote host, follow the instructions in the section called “Using pg_probackup in the Remote Mode”.

### Note

By default, the `restore` command validates the specified backup before restoring the cluster. If you run regular backup validations and would like to save time when restoring the cluster, you can specify the `--no-validate` flag to skip validation and speed up the recovery.

### Incremental Restore

The speed of restore from backup can be significantly improved by replacing only invalid and changed pages in already existing Postgres Pro data directory using incremental restore options with the `restore` command.

To restore the database cluster from a backup in incremental mode, run the `restore` command with the following options:

```
pg_probackup restore -B backup_dir --instance instance_name -D data_dir -I incremental_mode
```

Where `incremental_mode` can take one of the following values:

- **CHECKSUM** — read all data files in the data directory, validate header and checksum in every page and replace only invalid pages and those with checksum and LSN not matching with corresponding page in backup. This is the simplest, the most fool-proof incremental mode. Recommended to use by default.
- **LSN** — read the `pg_control` in the data directory to obtain redo LSN and redo TLI, which allows to determine a point in history(shiftpoint), where data directory state shifted from target backup chain history. If shiftpoint is not within reach of backup chain history, then restore is aborted. If shiftpoint is within reach of backup chain history, then read all data files in the data directory, validate header and checksum in every page and replace only invalid pages and those with LSN greater than shiftpoint. This mode offers a greater speed up compared to CHECKSUM, but rely on two conditions to be met. First, data checksums parameter must be enabled in data directory (to avoid corruption due to hint bits). This condition will be checked at the start of incremental restore and the operation will be aborted if checksums are disabled. Second, the `pg_control` file must be synched with state of data directory. This condition cannot checked at the start of restore, so it is a user responsibility to ensure that `pg_control` contain valid information. Therefore it is not recommended to use LSN mode in any situation, where `pg_control` cannot be trusted or has been tampered with: after `pg_resetxlog` execution, after restore from backup without recovery been run, etc.
- **NONE** — regular restore without any incremental optimizations.

Regardless of chosen incremental mode, `pg_probackup` will check, that postmaster in given destination directory is not running and system-identifier is the same as in the backup.

Suppose you want to return an old master as replica after switchover using incremental restore in LSN mode:
pg_probackup restore -B /backup --instance node -R -I lsn
INFO: Running incremental restore into nonempty directory: "/var/lib/pgsql/12/data"
INFO: Destination directory redo point 15/2E000028 on tli 16 is within reach of backup QBRIDX with Stop LSN 14/DD0000B8 on tli 15
INFO: shift LSN: 14/DD0000B8
INFO: Restoring the database from backup at 2020-06-11 17:40:58+03
INFO: Extracting the content of destination directory for incremental restore
INFO: Destination directory content extracted, time elapsed: 1s
INFO: Removing redundant files in destination directory
INFO: Redundant files are removed, time elapsed: 1s
INFO: Start restoring backup files. PGDATA size: 15GB
INFO: Backup files are restored. Transfered bytes: 1693MB, time elapsed: 43s
INFO: Restore incremental ratio (less is better): 11% (1693MB/15GB)
INFO: Restore of backup QBRNBP completed.
Partial restore relies on lax behavior of Postgres Pro recovery process toward truncated files. For recovery to work properly, files of excluded databases are restored as files of zero size. After the Postgres Pro cluster is successfully started, you must drop the excluded databases using `DROP DATABASE` command.

To decouple a single cluster containing multiple databases into separate clusters with minimal downtime, you can do partial restore of the cluster as a standby using the `--restore-as-replica` option for specific databases.

```
Note
The template0 and template1 databases are always restored.
```

```
Note
Due to recovery specifics of Postgres Pro versions earlier than 12, it is advisable that you set the hot_standby parameter to `off` when running partial restore of a Postgres Pro cluster of version earlier than 12. Otherwise the recovery may fail.
```

**Performing Point-in-Time (PITR) Recovery**

If you have enabled continuous WAL archiving before taking backups, you can restore the cluster to its state at an arbitrary point in time (recovery target) using recovery target options with the `restore` command.

You can use both STREAM and ARCHIVE backups for point in time recovery as long as the WAL archive is available at least starting from the time the backup was taken. If `--backup-id` option is omitted, `pg_probackup` automatically chooses the backup that is the closest to the specified recovery target and starts the restore process, otherwise `pg_probackup` will try to restore the specified backup to the specified recovery target.

- To restore the cluster state at the exact time, specify the `--recovery-target-time` option, in the timestamp format. For example:

  ```
  pg_probackup restore -B backup_dir --instance instance_name --recovery-target-time="2017-05-18 14:18:11+03"
  ```

- To restore the cluster state up to a specific transaction ID, use the `--recovery-target-xid` option:

  ```
  pg_probackup restore -B backup_dir --instance instance_name --recovery-target-xid=687
  ```

- To restore the cluster state up to the specific LSN, use `--recovery-target-lsn` option:

  ```
  pg_probackup restore -B backup_dir --instance instance_name --recovery-target-lsn=16/B374D848
  ```

- To restore the cluster state up to the specific named restore point, use `--recovery-target-name` option:

  ```
  pg_probackup restore -B backup_dir --instance instance_name --recovery-target-name="before_app_upgrade"
  ```

- To restore the backup to the latest state available in the WAL archive, use `--recovery-target` option with `latest` value:

  ```
  pg_probackup restore -B backup_dir --instance instance_name --recovery-target="latest"
  ```

2525
Additional Supplied Programs

- To restore the cluster to the earliest point of consistency, use the `--recovery-target` option with the `immediate` value:

  ```
  pg_probackup restore -B backup_dir --instance instance_name --recovery-target='immediate'
  ```

**Using pg_probackup in the Remote Mode**

`pg_probackup` supports the remote mode that allows to perform `backup` and `restore` operations remotely via SSH. In this mode, the backup catalog is stored on a local system, while Postgres Pro instance to be backed up is located on a remote system. You must have `pg_probackup` installed on both systems.

**Note**

`pg_probackup` relies on passwordless SSH connection for communication between the hosts.

The typical workflow is as follows:

- On your backup host, configure `pg_probackup` as explained in the section *Installation and Setup*. For the `add-instance` and `set-config` commands, make sure to specify `remote options` that point to the database host with the Postgres Pro instance.

- If you would like to take remote backups in PAGE mode, or rely on ARCHIVE WAL delivery mode, or use PITR, configure continuous WAL archiving from the database host to the backup host as explained in the section *Setting up continuous WAL archiving*. For the `archive-push` and `archive-get` commands, you must specify the `remote options` that point to the backup host with the backup catalog.

- Run `backup` or `restore` commands with `remote options` on the backup host. `pg_probackup` connects to the remote system via SSH and creates a backup locally or restores the previously taken backup on the remote system, respectively.

For example, to create an archive full backup of a Postgres Pro cluster located on a remote system with host address 192.168.0.2 on behalf of the `postgres` user via SSH connection through port 2302, run:

```
pg_probackup backup -B backup_dir --instance instance_name -b FULL --remote-user=postgres --remote-host=192.168.0.2 --remote-port=2302
```

To restore the latest available backup on a remote system with host address 192.168.0.2 on behalf of the `postgres` user via SSH connection through port 2302, run:

```
pg_probackup restore -B backup_dir --instance instance_name --remote-host=192.168.0.2 --remote-port=2302
```

Restoring an ARCHIVE backup or performing PITR in the remote mode require additional information: destination address, port and username for establishing an SSH connection from the host with database to the host with the backup catalog. This information will be used by the `restore_command` to copy WAL segments from the archive to the Postgres Pro `pg_wal` directory.

To solve this problem, you can use **Remote WAL Archive Options**.

For example, to restore latest backup on remote system using remote mode through SSH connection to user `postgres` on host with address 192.168.0.2 via port 2302 and user `backup` on backup catalog host with address 192.168.0.3 via port 2303, run:

```
pg_probackup restore -B backup_dir --instance instance_name --remote-user=postgres --remote-host=192.168.0.2 --remote-port=2302 --archive-host=192.168.0.3 --archive-port=2303 --archive-user=backup
```

Provided arguments will be used to construct the `restore_command`:
Additional Supplied Programs

```
restore_command = "install_dir/pg_probackup" archive-get -B "backup_dir" --
instance instance_name --wal-file-path=%p --wal-file-name=%f --remote-host=192.168.0.3
--remote-port=2303 --remote-user=backup'
```

Alternatively, you can use the `--restore-command` option to provide the entire `restore_command`:

```
pg_probackup restore -B backup_dir --instance instance_name --remote-user=postgres
--remote-host=192.168.0.2 --remote-port=2302 --restore-command="install_dir/
pg_probackup" archive-get -B "backup_dir" --instance instance_name --wal-file-path=%p
--wal-file-name=%f --remote-host=192.168.0.3 --remote-port=2303 --remote-user=backup'
```

**Note**
The remote mode is currently unavailable for Windows systems.

**Running pg_probackup on Parallel Threads**

Backup, restore, merge, delete, catchup, checkdb, and validate processes can be executed on several parallel threads. This can significantly speed up pg_probackup operation given enough resources (CPU cores, disk, and network bandwidth).

Parallel execution is controlled by the `-j/--threads` command-line option. For example, to create a backup using four parallel threads, run:

```
pg_probackup backup -B backup_dir --instance instance_name -b FULL -j 4
```

**Note**
Parallel restore applies only to copying data from the backup catalog to the data directory of the cluster. When Postgres Pro server is started, WAL records need to be replayed, and this cannot be done in parallel.

**Configuring pg_probackup**

Once the backup catalog is initialized and a new backup instance is added, you can use the `pg_probackup.conf` configuration file located in the `backup_dir/backups/instance_name` directory to fine-tune pg_probackup configuration.

For example, backup and checkdb commands use a regular Postgres Pro connection. To avoid specifying connection options each time on the command line, you can set them in the `pg_probackup.conf` configuration file using the `set-config` command.

**Note**
It is not recommended to edit `pg_probackup.conf` manually.

Initially, `pg_probackup.conf` contains the following settings:

- `PGDATA` — the path to the data directory of the cluster to back up.
- `system-identifier` — the unique identifier of the Postgres Pro instance.

Additionally, you can define remote, retention, logging, and compression settings using the `set-config` command:

```
pg_probackup set-config -B backup_dir --instance instance_name
[--external-dirs=external_directory_path] [remote_options] [connection_options]
[retention_options] [logging_options]
```
To view the current settings, run the following command:

```
pg_probackup show-config -B backup_dir --instance instance_name
```

You can override the settings defined in `pg_probackup.conf` when running `pg_probackup` commands via the corresponding environment variables and/or command line options.

**Specifying Connection Settings**

If you define connection settings in the `pg_probackup.conf` configuration file, you can omit connection options in all the subsequent `pg_probackup` commands. However, if the corresponding environment variables are set, they get higher priority. The options provided on the command line overwrite both environment variables and configuration file settings.

If nothing is given, the default values are taken. By default `pg_probackup` tries to use local connection via Unix domain socket (`localhost` on Windows) and tries to get the database name and the user name from the `PGUSER` environment variable or the current OS user name.

**Managing the Backup Catalog**

With `pg_probackup`, you can manage backups from the command line:

- View backup information
- View WAL Archive Information
- Validate backups
- Merge backups
- Delete backups

**Viewing Backup Information**

To view the list of existing backups for every instance, run the command:

```
pg_probackup show -B backup_dir
```

`pg_probackup` displays the list of all the available backups. For example:

```
BACKUP INSTANCE 'node'
======================================================================================================================================
Instance  Version  ID      Recovery time           Mode    WAL Mode  TLI  Time    Data          WAL  Zratio  Start LSN   Stop LSN    Status
======================================================================================================================================
node      10       PYSUE8  2019-10-03 15:51:48+03  FULL    ARCHIVE   1/0   16s  9047kB   16MB    4.31  0/12000028  0/12000160  OK
node      10       P7XDQV  2018-04-29 05:32:59+03  DELTA   STREAM    1/1   11s    19MB   16MB    1.00  0/15000060  0/15000198  OK
node      10       P7XDJA  2018-04-29 05:28:36+03  PTRACK  STREAM    1/1   21s    32MB   32MB    1.00  0/13000028  0/13000198  OK
node      10       P7XDHU  2018-04-29 05:27:59+03  PAGE    STREAM    1/1   15s    33MB   16MB    1.00  0/11000028  0/11000198  OK
node      10       P7XDHB  2018-04-29 05:27:15+03  FULL    STREAM    1/0   11s    39MB   16MB    1.00  0/F000028   0/F000198   OK
```

For each backup, the following information is provided:

- **Instance** — the instance name.
- **Version** — Postgres Pro major version.
- **ID** — the backup identifier.
- **Recovery time** — the earliest moment for which you can restore the state of the database cluster.
- **Mode** — the method used to take this backup. Possible values: FULL, PAGE, DELTA, PTRACK.
- **WAL Mode** — WAL delivery mode. Possible values: STREAM and ARCHIVE.
- **TLI** — timeline identifiers of the current backup and its parent.
• **Time** — the time it took to perform the backup.

• **Data** — the size of the data files in this backup. This value does not include the size of WAL files. For STREAM backups, the total size of the backup can be calculated as **Data + WAL**.

• **WAL** — the uncompressed size of WAL files that need to be applied during recovery for the backup to reach a consistent state.

• **Zratio** — compression ratio calculated as “uncompressed-bytes” / “data-bytes”.

• **Start LSN** — WAL log sequence number corresponding to the start of the backup process. REDO point for Postgres Pro recovery process to start from.

• **Stop LSN** — WAL log sequence number corresponding to the end of the backup process. Consistency point for Postgres Pro recovery process.

• **Status** — backup status. Possible values:
  - **OK** — the backup is complete and valid.
  - **DONE** — the backup is complete, but was not validated.
  - **RUNNING** — the backup is in progress.
  - **MERGING** — the backup is being merged.
  - **MERGED** — the backup data files were successfully merged, but its metadata is in the process of being updated. Only full backups can have this status.
  - **DELETING** — the backup files are being deleted.
  - **CORRUPT** — some of the backup files are corrupt.
  - **ERROR** — the backup was aborted because of an unexpected error.
  - **ORPHAN** — the backup is invalid because one of its parent backups is corrupt or missing.

You can restore the cluster from the backup only if the backup status is **OK** or **DONE**.

To get more detailed information about the backup, run the `show` command with the backup ID:

```
pg_probackup show -B backup_dir --instance instance_name -i backup_id
```

The sample output is as follows:

```
#Configuration
backup-mode = FULL
stream = false
compress-alg = zlib
compress-level = 1
from-replica = false

#Compatibility
block-size = 8192
wal-block-size = 8192
checksum-version = 1
program-version = 2.1.3
server-version = 10

#Result backup info
timelineid = 1
start-lsn = 0/04000028
stop-lsn = 0/040000f8
start-time = '2017-05-16 12:57:29'
end-time = '2017-05-16 12:57:31'
recovery-xid = 597
recovery-time = '2017-05-16 12:57:31'
expire-time = '2020-05-16 12:57:31'
data-bytes = 22288792
wal-bytes = 16777216
```
uncompressed-bytes = 39961833
pgdata-bytes = 39859393
status = OK
parent-backup-id = 'PT8XFX'
primary_conninfo = 'user=backup passfile=/var/lib/pgsql/.pgpass port=5432
sslmode=disable sslcompression=1 target_session_attrs=any'

Detailed output has additional attributes:

• compress-alg — compression algorithm used during backup. Possible values: zlib, pglz, none.
• compress-level — compression level used during backup.
• from-replica — was this backup taken on standby? Possible values: 1, 0.
• block-size — the block_size setting of Postgres Pro cluster at the backup start.
• checksum-version — are data_checkums enabled in the backed up Postgres Pro cluster? Possible values: 1, 0.
• program-version — full version of pg_probackup binary used to create the backup.
• start-time — the backup start time.
• end-time — the backup end time.
• expire-time — the point in time when a pinned backup can be removed in accordance with retention policy. This attribute is only available for pinned backups.
• uncompressed-bytes — the size of data files before adding page headers and applying compression. You can evaluate the effectiveness of compression by comparing uncompressed-bytes to pgdata-bytes if compression if used.
• pgdata-bytes — the size of Postgres Pro cluster data files at the time of backup. You can evaluate the effectiveness of an incremental backup by comparing pgdata-bytes to uncompressed-bytes.
• recovery-xid — transaction ID at the backup end time.
• parent-backup-id — ID of the parent backup. Available only for incremental backups.
• primary_conninfo — libpq connection parameters used to connect to the Postgres Pro cluster to take this backup. The password is not included.
• note — text note attached to backup.
• content-crc — CRC32 checksum of backup_content.control file. It is used to detect corruption of backup metainformation.

You can also get the detailed information about the backup in the JSON format:

pg_probackup show -B backup_dir --instance instance_name --format=json -i backup_id

The sample output is as follows:

```json

Viewing WAL Archive Information

To view the information about WAL archive for every instance, run the command:

```
pg_probackup show -B backup_dir [--instance instance_name] --archive
```

pg_probackup displays the list of all the available WAL files grouped by timelines. For example:

```
ARCHIVE INSTANCE 'node'
===================================================================================================================================
TLI  Parent TLI  Switchpoint  Min Segno                 Max Segno                 N segments  Size    Zratio  N backups  Status
===================================================================================================================================
5    1           0/B000000    00000005000000000000000B  00000005000000000000000C  2 685kB   48.00   0          OK
4    3           0/18000000   00000004000000000000001A  000000040000000000000018  3 648kB   77.00   0          OK
3    2           0/15000000   000000030000000000000015  000000030000000000000017  3 648kB   77.00   0          OK
2    1           0/B000108    00000002000000000000000B  000000020000000000000015  5 892kB   94.00   1          DEGRADED
1    0           0/0          000000010000000000000001  00000001000000000000000A  10 8774kB  19.00   1          OK
```

For each timeline, the following information is provided:

- **TLI** — timeline identifier.
- **Parent TLI** — identifier of the timeline from which this timeline branched off.
- **Switchpoint** — LSN of the moment when the timeline branched off from its parent timeline.
- **Min Segno** — the first WAL segment belonging to the timeline.
- **Max Segno** — the last WAL segment belonging to the timeline.
- **N segments** — number of WAL segments belonging to the timeline.
- **Size** — the size that files take on disk.
- **Zratio** — compression ratio calculated as \( \frac{N \text{ segments} \times \text{wal_segment_size} \times \text{wal_block_size}}{\text{Size}} \).
- **N backups** — number of backups belonging to the timeline. To get the details about backups, use the JSON format.
- **Status** — status of the WAL archive for this timeline. Possible values:
  - **OK** — all WAL segments between **Min Segno** and **Max Segno** are present.
  - **DEGRADED** — some WAL segments between **Min Segno** and **Max Segno** are missing. To find out which files are lost, view this report in the JSON format.

To get more detailed information about the WAL archive in the JSON format, run the command:

```
pg_probackup show -B backup_dir [--instance instance_name] --archive --format=json
```
The sample output is as follows:

```json
[
  {
    "instance": "replica",
    "timelines": [
      {
        "tli": 5,
        "parent-tli": 1,
        "switchpoint": "0/B000000",
        "min-segno": "00000005000000000000000B",

Most fields are consistent with the plain format, with some exceptions:

- The size is in bytes.
- The `closest-backup-id` attribute contains the ID of the most recent valid backup that belongs to one of the previous timelines. You can use this backup to perform point-in-time recovery to this timeline. If such a backup does not exist, this string is empty.
- The `lost-segments` array provides information about intervals of missing segments in DEGRADED timelines. In OK timelines, the `lost-segments` array is empty.
- The `backups` array lists all backups belonging to the timeline. If the timeline has no backups, this array is empty.

Configuring Retention Policy

With pg_probackup, you can configure retention policy to remove redundant backups, clean up unneeded WAL files, as well as pin specific backups to ensure they are kept for the specified time, as explained in the sections below. All these actions can be combined together in any way.
Removing Redundant Backups

By default, all backup copies created with pg_probackup are stored in the specified backup catalog. To save disk space, you can configure retention policy to remove redundant backup copies.

To configure retention policy, set one or more of the following variables in the `pg_probackup.conf` file via `set-config`:

```
--retention-redundancy=redun
dancy
```

Specifies the number of full backup copies to keep in the backup catalog.

```
--retention-window=window
```

Defines the earliest point in time for which pg_probackup can complete the recovery. This option is set in the number of days from the current moment. For example, if `retention-window=7`, pg_probackup must keep at least one backup copy that is older than seven days, with all the corresponding WAL files, and all the backups that follow.

If both `--retention-redundancy` and `--retention-window` options are set, both these conditions have to be taken into account when purging the backup catalog. For example, if you set `--retention-redundancy=2` and `--retention-window=7`, pg_probackup has to keep two full backup copies, as well as all the backups required to ensure recoverability for the last seven days:

```
pg_probackup set-config -B backup_dir --instance instance_name --retention-redundancy=2 --retention-window=7
```

To clean up the backup catalog in accordance with retention policy, you have to run the delete command with retention flags, as shown below, or use the backup command with these flags to process the outdated backup copies right when the new backup is created.

For example, to remove all backup copies that no longer satisfy the defined retention policy, run the following command with the `--delete-expired` flag:

```
pg_probackup delete -B backup_dir --instance instance_name --delete-expired
```

If you would like to also remove the WAL files that are no longer required for any of the backups, you should also specify the `--delete-wal` flag:

```
pg_probackup delete -B backup_dir --instance instance_name --delete-expired --delete-wal
```

You can also set or override the current retention policy by specifying `--retention-redundancy` and `--retention-window` options directly when running delete or backup commands:

```
pg_probackup delete -B backup_dir --instance instance_name --delete-expired --retention-redundancy=2 --retention-window=7
```

Since incremental backups require that their parent full backup and all the preceding incremental backups are available, if any of such backups expire, they still cannot be removed while at least one incremental backup in this chain satisfies the retention policy. To avoid keeping expired backups that are still required to restore an active incremental one, you can merge them with this backup using the `--merge-expired` flag when running backup or delete commands.

Suppose you have backed up the `node` instance in the `backup_dir` directory, with the `--retention-window` option set to 7, and you have the following backups available on April 10, 2019:

```
BACKUP INSTANCE 'node'
===================================================================================================================================
Instance  Version  ID      Recovery time           Mode   WAL     TLI  Time    Data
WAL  Zratio  Start LSN   Stop LSN    Status
===================================================================================================================================
node      10       P7XDHR  2019-04-10 05:27:15+03  FULL   STREAM  1/0   11s   200MB
          16MB     1.0  0/18000059  0/18000197  OK
```

```
2536
Even though P7XDHB and P7XDHU backups are outside the retention window, they cannot be removed as it invalidates the succeeding incremental backups P7XDJA and P7XDQV that are still required, so, if you run the delete command with the --delete-expired flag, only the P7XDFT full backup will be removed.

With the --merge-expired option, the P7XDJA backup is merged with the underlying P7XDHU and P7XDBH backups and becomes a full one, so there is no need to keep these expired backups anymore:

```
pg_probackup delete -B backup_dir --instance node --delete-expired --merge-expired
```

```
pg_probackup show -B backup_dir
```

```
BACKUP INSTANCE 'node'
```

<table>

</tr>
</tbody>
</table>

The Time field for the merged backup displays the time required for the merge.

**Pinning Backups**

If you need to keep certain backups longer than the established retention policy allows, you can pin them for arbitrary time. For example:

```
pg_probackup set-backup -B backup_dir --instance instance_name -i backup_id --ttl=30d
```

This command sets the expiration time of the specified backup to 30 days starting from the time indicated in its recovery-time attribute.

You can also explicitly set the expiration time for a backup using the --expire-time option. For example:

```
pg_probackup set-backup -B backup_dir --instance instance_name -i backup_id --expire-time="2020-01-01 00:00:00+03"
```

Alternatively, you can use the --ttl and --expire-time options with the backup command to pin the newly created backup:

```
pg_probackup backup -B backup_dir --instance instance_name -b FULL --ttl=30d
```

```
pg_probackup backup -B backup_dir --instance instance_name -b FULL --expire-time="2020-01-01 00:00:00+03"
```

To check if the backup is pinned, run the show command:

```
pg_probackup show -B backup_dir --instance instance_name -i backup_id
```

If the backup is pinned, it has the expire-time attribute that displays its expiration time:
recovery-time = '2017-05-16 12:57:31'
expire-time = '2020-01-01 00:00:00+03'
data-bytes = 22288792
...

You can unpin the backup by setting the --ttl option to zero:

```
pg_probackup set-backup -B backup_dir --instance instance_name -i backup_id --ttl=0
```

**Note**

A pinned incremental backup implicitly pins all its parent backups. If you unpin such a backup later, its implicitly pinned parents will also be automatically unpinned.

### Configuring WAL Archive Retention Policy

When **continuous WAL archiving** is enabled, archived WAL segments can take a lot of disk space. Even if you delete old backup copies from time to time, the **--delete-wal** flag can purge only those WAL segments that do not apply to any of the remaining backups in the backup catalog. However, if point-in-time recovery is critical only for the most recent backups, you can configure WAL archive retention policy to keep WAL archive of limited depth and win back some more disk space.

To configure WAL archive retention policy, you have to run the `set-config` command with the **--wal-depth** option that specifies the number of backups that can be used for PITR. This setting applies to all the timelines, so you should be able to perform PITR for the same number of backups on each timeline, if available. **Pinned backups** are not included into this count: if one of the latest backups is pinned, `pg_probackup` ensures that PITR is possible for one extra backup.

To remove WAL segments that do not satisfy the defined WAL archive retention policy, you simply have to run the **delete** or **backup** command with the **--delete-wal** flag. For archive backups, WAL segments between Start LSN and Stop LSN are always kept intact, so such backups remain valid regardless of the **--wal-depth setting** and can still be restored, if required.

You can also use the **--wal-depth** option with the delete and backup commands to override the previously defined WAL archive retention policy and purge old WAL segments on the fly.

**Suppose you have backed up** the node **instance** in the **backup_dir** directory and configured **continuous WAL archiving**:

```
pg_probackup show -B backup_dir --instance node
```

<table>
<thead>
<tr>
<th>Instance</th>
<th>Version</th>
<th>ID</th>
<th>Recovery Time</th>
<th>Mode</th>
<th>WAL Mode</th>
<th>TLI</th>
<th>Time</th>
<th>Data</th>
</tr>
</thead>
<tbody>
<tr>
<td>node</td>
<td>11</td>
<td>PZ9442</td>
<td>2019-10-12 10:43:21+03</td>
<td>DELTA</td>
<td>STREAM</td>
<td>1/0</td>
<td>10s</td>
<td>121kB</td>
</tr>
<tr>
<td>node</td>
<td>11</td>
<td>PZ943L</td>
<td>2019-10-12 10:43:04+03</td>
<td>FULL</td>
<td>STREAM</td>
<td>1/0</td>
<td>10s</td>
<td>180MB</td>
</tr>
<tr>
<td>node</td>
<td>11</td>
<td>PZ7YR5</td>
<td>2019-10-11 19:49:56+03</td>
<td>DELTA</td>
<td>STREAM</td>
<td>1/0</td>
<td>10s</td>
<td>112kB</td>
</tr>
<tr>
<td>node</td>
<td>11</td>
<td>PZ7YM5</td>
<td>2019-10-11 19:47:16+03</td>
<td>DELTA</td>
<td>STREAM</td>
<td>1/0</td>
<td>10s</td>
<td>376kB</td>
</tr>
<tr>
<td>node</td>
<td>11</td>
<td>PZ7YK2</td>
<td>2019-10-11 19:45:45+03</td>
<td>FULL</td>
<td>STREAM</td>
<td>1/0</td>
<td>11s</td>
<td>180MB</td>
</tr>
<tr>
<td>node</td>
<td>11</td>
<td>PZ7YFO</td>
<td>2019-10-11 19:43:04+03</td>
<td>FULL</td>
<td>STREAM</td>
<td>1/0</td>
<td>10s</td>
<td>30MB</td>
</tr>
</tbody>
</table>
You can check the state of the WAL archive by running the `show` command with the `--archive` flag:

```sql
pg_probackup show -B backup_dir --instance node --archive
```

```
ARCHIVE INSTANCE 'node'

<table>
<thead>
<tr>
<th>TLI</th>
<th>Parent TLI</th>
<th>Switchpoint</th>
<th>Min Segno</th>
<th>Max Segno</th>
<th>N backups</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
<td>0/0</td>
<td>00000001000000000000000000000001</td>
<td>00000001000000000000000000000047</td>
<td>71</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>36MB</td>
<td>31.00</td>
<td>6</td>
<td>OK</td>
</tr>
</tbody>
</table>
```

WAL purge without `--wal-depth` cannot achieve much, only one segment is removed:

```sql
pg_probackup delete -B backup_dir --instance node --delete-wal
```

```
ARCHIVE INSTANCE 'node'

<table>
<thead>
<tr>
<th>TLI</th>
<th>Parent TLI</th>
<th>Switchpoint</th>
<th>Min Segno</th>
<th>Max Segno</th>
<th>N backups</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
<td>0/0</td>
<td>00000001000000000000000000000002</td>
<td>00000001000000000000000000000047</td>
<td>70</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>34MB</td>
<td>32.00</td>
<td>6</td>
<td>OK</td>
</tr>
</tbody>
</table>
```

If you would like, for example, to keep only those WAL segments that can be applied to the latest valid backup, set the `--wal-depth` option to 1:

```sql
pg_probackup delete -B backup_dir --instance node --delete-wal --wal-depth=1
```

```
ARCHIVE INSTANCE 'node'

<table>
<thead>
<tr>
<th>TLI</th>
<th>Parent TLI</th>
<th>Switchpoint</th>
<th>Min Segno</th>
<th>Max Segno</th>
<th>N backups</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
<td>0/0</td>
<td>00000001000000000000000000000046</td>
<td>00000001000000000000000000000047</td>
<td>2</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>143kB</td>
<td>228.00</td>
<td>6</td>
<td>OK</td>
</tr>
</tbody>
</table>
```

Alternatively, you can use the `--wal-depth` option with the `backup` command:

```sql
pg_probackup backup -B backup_dir --instance node -b DELTA --wal-depth=1 --delete-wal
```

```
ARCHIVE INSTANCE 'node'

<table>
<thead>
<tr>
<th>TLI</th>
<th>Parent TLI</th>
<th>Switchpoint</th>
<th>Min Segno</th>
<th>Max Segno</th>
<th>N backups</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
<td>0/0</td>
<td>00000001000000000000000000000048</td>
<td>00000001000000000000000000000049</td>
<td>1</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>72kB</td>
<td>228.00</td>
<td>7</td>
<td>OK</td>
</tr>
</tbody>
</table>
```

### Merging Backups

As you take more and more incremental backups, the total size of the backup catalog can substantially grow. To save disk space, you can merge incremental backups to their parent full backup by running the `merge` command, specifying the backup ID of the most recent incremental backup you would like to merge:

```sql
pg_probackup merge -B backup_dir --instance instance_name -i backup_id
```

This command merges backups that belong to a common incremental backup chain. If you specify a full backup, it will be merged with its first incremental backup. If you specify an incremental backup, it will be merged to its parent full backup, together with all incremental backups between them. Once the merge is complete, the full backup takes in all the merged data, and the incremental backups are removed as redundant. Thus, the merge operation is virtually equivalent to retaking a full backup and...
removing all the outdated backups, but it allows to save much time, especially for large data volumes, as well as I/O and network traffic if you are using pg_probackup in the remote mode.

Before the merge, pg_probackup validates all the affected backups to ensure that they are valid. You can check the current backup status by running the show command with the backup ID:

```bash
pg_probackup show -B backup_dir --instance instance_name -i backup_id
```

If the merge is still in progress, the backup status is displayed as MERGING. For full backups, it can also be shown as MERGED while the metadata is being updated at the final stage of the merge. The merge is idempotent, so you can restart the merge if it was interrupted.

### Deleting Backups

To delete a backup that is no longer required, run the following command:

```bash
pg_probackup delete -B backup_dir --instance instance_name -i backup_id
```

This command will delete the backup with the specified backup_id, together with all the incremental backups that descend from backup_id, if any. This way you can delete some recent incremental backups, retaining the underlying full backup and some of the incremental backups that follow it.

To delete obsolete WAL files that are not necessary to restore any of the remaining backups, use the --delete-wal flag:

```bash
pg_probackup delete -B backup_dir --instance instance_name --delete-wal
```

To delete backups that are expired according to the current retention policy, use the --delete-expired flag:

```bash
pg_probackup delete -B backup_dir --instance instance_name --delete-expired
```

Expired backups cannot be removed while at least one incremental backup that satisfies the retention policy is based on them. If you would like to minimize the number of backups still required to keep incremental backups valid, specify the --merge-expired flag when running this command:

```bash
pg_probackup delete -B backup_dir --instance instance_name --delete-expired --merge-expired
```

In this case, pg_probackup searches for the oldest incremental backup that satisfies the retention policy and merges this backup with the underlying full and incremental backups that have already expired, thus making it a full backup. Once the merge is complete, the remaining expired backups are deleted.

Before merging or deleting backups, you can run the delete command with the --dry-run flag, which displays the status of all the available backups according to the current retention policy, without performing any irreversible actions.

To delete all backups with specific status, use the --status:

```bash
pg_probackup delete -B backup_dir --instance instance_name --status=ERROR
```

Deleting backups by status ignores established retention policies.

### Cloning and Synchronizing Postgres Pro Instance

pg_probackup can create a copy of a Postgres Pro instance directly, without using the backup catalog. To do this, you can run the catchup command. It can be useful in the following cases:

- To add a new standby server:

  Usually, pg_basebackup is used to create a copy of a Postgres Pro instance. If the data directory of the destination instance is empty, the catchup command works similarly, but it can be faster if run in parallel mode.
To have a fallen-behind standby server “catch up” with master.

Under write-intensive load, replicas may fail to replay WAL fast enough to keep up with master and hence may lag behind. A usual solution to create a new replica and switch to it requires a lot of extra space and data transfer. The `catchup` command allows you to update an existing replica much faster by bringing differences from master.

`catchup` is different from other `pg_probackup` operations:

- The backup catalog is not required.
- STREAM WAL delivery mode is only supported.
- Copying external directories is not supported.
- DDL commands `CREATE TABLESPACE/DROP TABLESPACE` cannot be run simultaneously with `catchup`.

`catchup` takes configuration files, such as `postgresql.conf`, `postgresql.auto.conf`, or `pg_hba.conf`, from the source server and overwrites them on the target server. The `--exclude-path` option allows you to keep the configuration files intact.

To prepare for cloning/synchronizing a Postgres Pro instance, set up the source instance server as follows:

- Configure the database cluster for the instance to copy.
- To copy from a remote server, configure the remote mode.
- To use the PTRACK catchup mode, set up PTRACK backups.

Before cloning/synchronizing a Postgres Pro instance, ensure that the source instance server is running and accepting connections. To clone/sync a Postgres Pro instance, on the server with the destination instance, you can run the `catchup` command as follows:

```
pg_probackup catchup -b catchup_mode --source-pgdata=path_to_pgdata_on_remote_server --destination-pgdata=path_to_local_dir --stream [connection_options] [remote_options]
```

Where `catchup_mode` can take one of the following values: FULL, DELTA, or PTRACK.

- FULL — creates a full copy of the Postgres Pro instance. The data directory of the destination instance must be empty for this mode.
- DELTA — reads all data files in the data directory and creates an incremental copy for pages that have changed since the destination instance was shut down.
- PTRACK — tracking page changes on the fly, only reads and copies pages that have changed since the point of divergence of the source and destination instances.

**Warning**

PTRACK catchup mode requires PTRACK not earlier than 2.0 and hence, Postgres Pro not earlier than 11.

By specifying the `--stream` option, you can set STREAM WAL delivery mode of copying, which will include all the necessary WAL files by streaming them from the instance server via replication protocol.

You can use `connection_options` to specify the connection to the source database cluster. If it is located on a different server, also specify `remote_options`.

If the source database cluster contains tablespaces that must be located in a different directory, additionally specify the `--tablespace-mapping` option:

```
pg_probackup catchup -b catchup_mode --source-pgdata=path_to_pgdata_on_remote_server --destination-pgdata=path_to_local_dir --stream --tablespace-mapping=OLDDIR=NEWDIR
```
To run the `catchup` command on parallel threads, specify the number of threads with the `--threads` option:

```
pg_probackup catchup -b catchup_mode --source-pgdata=path_to_pgdatal_on_remote_server --destination-pgdata=path_to_local_dir --stream --threads=num_threads
```

For example, assume that a remote standby server with the Postgres Pro instance having `/replica-pgdata` data directory has fallen behind. To sync this instance with the one in `/master-pgdata` data directory, you can run the `catchup` command in the PTRACK mode on four parallel threads as follows:

```
```

Note that in this example, the configuration files will not be overwritten during synchronization.

Another example shows how you can add a new remote standby server with the Postgres Pro data directory `/replica-pgdata` by running the `catchup` command in the FULL mode on four parallel threads:

```
pg_probackup catchup --source-pgdata=/master-pgdata --destination-pgdata=/replica-pgdata -p 5432 -d postgres -U remote-postgres-user --stream --backup-mode=FULL --remote-host=remote-hostname --remote-user=remote-username -j 4
```

**Command-Line Reference**

**Commands**

This section describes `pg_probackup` commands. Optional parameters are enclosed in square brackets. For detailed parameter descriptions, see the section [Options](#options).

### version

```
pg_probackup version
```

Prints `pg_probackup` version.

### help

```
pg_probackup help [command]
```

Displays the synopsis of `pg_probackup` commands. If one of the `pg_probackup` commands is specified, shows detailed information about the options that can be used with this command.

### init

```
pg_probackup init -B backup_dir [--help]
```

Initializes the backup catalog in `backup_dir` that will store backup copies, WAL archive, and meta information for the backed up database clusters. If the specified `backup_dir` already exists, it must be empty. Otherwise, `pg_probackup` displays a corresponding error message.

For details, see the section [Initializing the Backup Catalog](#initializing-the-backup-catalog).

### add-instance

```
pg_probackup add-instance -B backup_dir -D data_dir --instance instance_name [--help]
```

Initializes a new backup instance inside the backup catalog `backup_dir` and generates the `pg_probackup.conf` configuration file that controls `pg_probackup` settings for the cluster with the specified `data_dir` data directory.

For details, see the section [Adding a New Backup Instance](#adding-a-new-backup-instance).

### del-instance

```
pg_probackup del-instance -B backup_dir --instance instance_name [--help]
```

---

2542
Deletes all backups and WAL files associated with the specified instance.

**set-config**

```bash
gp_probackup set-config -B backup_dir --instance instance_name
[--help] [--pgdata=pgdata-path]
[--retention-redundancy=redundancy] [--retention-window=window] [--wal-depth=wal_depth]
[--compress-algorithm=compression_algorithm] [--compress-level=compression_level]
[--dbname] [--host] [--port] [--username]
[--archive-timeout=timeout] [--external-dirs=external_directory_path]
[--restore-command=cmdline]
```

Adds the specified connection, compression, retention, logging, and external directory settings into the `pg_probackup.conf` configuration file, or modifies the previously defined values.

For all available settings, see the Options section.

It is **not recommended** to edit `pg_probackup.conf` manually.

**set-backup**

```bash
gp_probackup set-backup -B backup_dir --instance instance_name -i backup_id
[--ttl=ttl | --expire-time=time]
[--note=backup_note] [--help]
```

Sets the provided backup-specific settings into the `backup.control` configuration file, or modifies the previously defined values.

**--note=backup_note**

Sets the text note for backup copy. If `backup_note` contain newline characters, then only substring before first newline character will be saved. Max size of text note is 1 KB. The 'none' value removes current note.

For all available pinning settings, see the section Pinning Options.

**show-config**

```bash
gp_probackup show-config -B backup_dir --instance instance_name
```

Displays the contents of the `pg_probackup.conf` configuration file located in the `backup_dir/backups/instance_name` directory. You can specify the `--format=json` option to get the result in the JSON format.

By default, configuration settings are shown as plain text.

To edit `pg_probackup.conf`, use the `set-config` command.

**show**

```bash
gp_probackup show -B backup_dir
```

Shows the contents of the backup catalog. If `instance_name` and `backup_id` are specified, shows detailed information about this backup. If the `--archive` option is specified, shows the contents of WAL archive of the backup catalog.

By default, the contents of the backup catalog is shown as plain text. You can specify the `--format=json` option to get the result in the JSON format. If `--no-color` flag is used, then the output is not colored.

For details on usage, see the sections Managing the Backup Catalog and Viewing WAL Archive Information.

**backup**

```bash
gp_probackup backup -B backup_dir -b backup_mode --instance instance_name
```

2543
Additional Supplied Programs

Creates a backup copy of the Postgres Pro instance.

`-b mode`  
`--backup-mode=mode`

Specifies the backup mode to use. Possible values are:

- **FULL** — creates a full backup that contains all the data files of the cluster to be restored.
- **DELTA** — reads all data files in the data directory and creates an incremental backup for pages that have changed since the previous backup.
- **PAGE** — creates an incremental PAGE backup based on the WAL files that have changed since the previous full or incremental backup was taken.
- **PTRACK** — creates an incremental PTRACK backup tracking page changes on the fly.

`-C`  
`--smooth-checkpoint`

Spreads out the checkpoint over a period of time. By default, pg_probackup tries to complete the checkpoint as soon as possible.

`--stream`

Makes a **STREAM** backup, which includes all the necessary WAL files by streaming them from the database server via replication protocol.

`--temp-slot`

Creates a temporary physical replication slot for streaming WAL from the backed up Postgres Pro instance. It ensures that all the required WAL segments remain available if WAL is rotated while the backup is in progress. This flag can only be used together with the `--stream` flag. The default slot name is `pg_probackup_slot`, which can be changed using the `--slot/-S` option.

`-S slot_name`  
`--slot=slot_name`

Specifies the replication slot for WAL streaming. This option can only be used together with the `--stream` flag.

`--backup-pg-log`

Includes the log directory into the backup. This directory usually contains log messages. By default, log directory is excluded.

`-E external_directory_path`  
`--external-dirs=external_directory_path`

Includes the specified directory into the backup by recursively copying its contents into a separate subdirectory in the backup catalog. This option is useful to back up scripts, SQL dump files, and configuration files located outside of the data directory. If you would like to back up several external directories, separate their paths by a colon on Unix and a semicolon on Windows.

`--archive-timeout=wait_time`

Sets the timeout for WAL segment archiving and streaming, in seconds. By default, pg_probackup waits 300 seconds.
--skip-block-validation

Disables block-level checksum verification to speed up the backup process.

--no-validate

Skips automatic validation after the backup is taken. You can use this flag if you validate backups regularly and would like to save time when running backup operations.

--no-sync

Do not sync backed up files to disk. You can use this flag to speed up the backup process. Using this flag can result in data corruption in case of operating system or hardware crash. If you use this option, it is recommended to run the validate command once the backup is complete to detect possible issues.

--note=backup_note

Sets the text note for backup copy. If backup_note contain newline characters, then only substring before first newline character will be saved. Max size of text note is 1 KB. The 'none' value removes current note.

Additionally, connection options, retention options, pinning options, remote mode options, compression options, logging options, and common options can be used.

For details on usage, see the section Creating a Backup.

restore

pg_probackup restore -B backup_dir --instance instance_name
[--help] [-D data_dir] [-i backup_id]
[-j num_threads] [--progress]
[-T OLDDIR=NEWDIR] [--external-mapping=OLDDIR=NEWDIR] [--skip-external-dirs]
[--force] [--no-sync]
[--restore-command=cmdline]
[--primary-conninfo=primary_conninfo]
[-S | --primary-slot-name=slot_name]
[recovery_target_options] [logging_options] [remote_options]
[partial_restore_options] [remote_wal_archive_options]

Restores the Postgres Pro instance from a backup copy located in the backup_dir backup catalog. If you specify a recovery target option, pg_probackup finds the closest backup and restores it to the specified recovery target. If neither the backup ID nor recovery target options are provided, pg_probackup uses the most recent backup to perform the recovery.

-R

--restore-as-replica

Creates a minimal recovery configuration file to facilitate setting up a standby server. If the replication connection requires a password, you must specify the password manually in the primary_conninfo parameter as it is not included. For Postgres Pro 11 or lower, recovery settings are written into the recovery.conf file. Starting from Postgres Pro 12, pg_probackup writes these settings into the probackup_recovery.conf file in the data directory, and then includes them into the postgresql.auto.conf when the cluster is started.

--primary-conninfo=primary_conninfo

Sets the primary_conninfo parameter to the specified value. This option will be ignored unless the -R flag is specified.

Example: --primary-conninfo="host=192.168.1.50 port=5432 user=foo password=foopass"
Additional Supplied Programs

-S
--primary-slot-name=slot_name

Sets the primary_slot_name parameter to the specified value. This option will be ignored unless the -R flag is specified.

-T OLDDIR=NEWDIR
--tablespace-mapping=OLDDIR=NEWDIR

Relocates the tablespace from the OLDDIR to the NEWDIR directory at the time of recovery. Both OLDDIR and NEWDIR must be absolute paths. If the path contains the equals sign (=), escape it with a backslash. This option can be specified multiple times for multiple tablespacess.

--external-mapping=OLDDIR=NEWDIR

Relocates an external directory included into the backup from the OLDDIR to the NEWDIR directory at the time of recovery. Both OLDDIR and NEWDIR must be absolute paths. If the path contains the equals sign (=), escape it with a backslash. This option can be specified multiple times for multiple directories.

--skip-external-dirs

Skip external directories included into the backup with the --external-dirs option. The contents of these directories will not be restored.

--skip-block-validation

Disables block-level checksum verification to speed up validation. During automatic validation before the restore only file-level checksums will be verified.

--no-validate

Skips backup validation. You can use this flag if you validate backups regularly and would like to save time when running restore operations.

--restore-command=cmdline

Sets the restore_command parameter to the specified command. For example: --restore-command='cp /mnt/server/archivedir/%f "$p"'

--force

Allows to ignore an invalid status of the backup. You can use this flag if you need to restore the Postgres Pro cluster from a corrupt or an invalid backup. Use with caution. If PGDATA contains a non-empty directory with system ID different from that of the backup being restored, incremental restore with this flag overwrites the directory contents (while an error occurs without the flag). If tablespaces are remapped through the --tablespace-mapping option into non-empty directories, the contents of such directories will be deleted.

--no-sync

Do not sync restored files to disk. You can use this flag to speed up restore process. Using this flag can result in data corruption in case of operating system or hardware crash. If it happens, you have to run the restore command again.

Additionally, recovery target options, remote mode options, remote WAL archive options, logging options, partial restore options, and common options can be used.

For details on usage, see the section Restoring a Cluster.

ccheckdb

g_probackup checkdb
[-B backup_dir] [--instance instance_name] [-D data_dir]
Additional Supplied Programs

[--help] [-j num_threads] [--progress]
[--skip-block-validation] [--amcheck] [--heapallindexed]
[connection_options] [logging_options]

Verifies the Postgres Pro database cluster correctness by detecting physical and logical corruption.

--amcheck
Performs logical verification of indexes for the specified Postgres Pro instance if no corruption was found while checking data files. You must have the amcheck extension or the amcheck_next extension installed in the database to check its indexes. For databases without amcheck, index verification will be skipped.

--skip-block-validation
Skip validation of data files. You can use this flag only together with the --amcheck flag, so that only logical verification of indexes is performed.

--heapallindexed
Checks that all heap tuples that should be indexed are actually indexed. You can use this flag only together with the --amcheck flag.

This check is only possible if you are using the amcheck extension of version 2.0 or higher, or the amcheck_next extension of any version.

Additionally, connection options and logging options can be used.

For details on usage, see the section Verifying a Cluster.

validate

pg_probackup validate -B backup_dir
[--help] [--instance instance_name] [-i backup_id]
[-j num_threads] [--progress]
[--skip-block-validation]
[recovery_target_options] [logging_options]

Verifies that all the files required to restore the cluster are present and are not corrupt. If instance_name is not specified, pg_probackup validates all backups available in the backup catalog. If you specify the instance_name without any additional options, pg_probackup validates all the backups available for this backup instance. If you specify the instance_name with a recovery target option and/or a backup_id, pg_probackup checks whether it is possible to restore the cluster using these options.

For details, see the section Validating a Backup.

merge

pg_probackup merge -B backup_dir --instance instance_name -i backup_id
[logging_options]

Merges backups that belong to a common incremental backup chain. If you specify a full backup, it will be merged with its first incremental backup. If you specify an incremental backup, it will be merged to its parent full backup, together with all incremental backups between them. Once the merge is complete, the full backup takes in all the merged data, and the incremental backups are removed as redundant.

--no-validate
Skips automatic validation before and after merge.

--no-sync
Do not sync merged files to disk. You can use this flag to speed up the merge process. Using this flag can result in data corruption in case of operating system or hardware crash.
Additional Supplied Programs

For details, see the section Merging Backups.

**delete**

```bash
go_probackup delete -B backup_dir --instance instance_name
[--help] [-j num_threads] [--progress]
[--retention-redundancy=redundancy][--retention-window=window][--wal-depth=wal_depth]
[--delete-wal]
(-i backup_id | --delete-expired --merge-expired) | --merge-expired | --
status=backup_status)
[--dry-run] [--no-validate] [--no-sync] [logging_options]
```

Deletes backup with specified `backup_id` or launches the retention purge of backups and archived WAL that do not satisfy the current retention policies.

--no-validate

Skips automatic validation before and after retention merge.

--no-sync

Do not sync merged files to disk. You can use this flag to speed up the retention merge process. Using this flag can result in data corruption in case of operating system or hardware crash.

For details, see the sections Deleting Backups, Retention Options, and Configuring Retention Policy.

**archive-push**

```bash
go_probackup archive-push -B backup_dir --instance instance_name
--wal-file-name=wal_file_name [--wal-file-path=wal_file_path]
[-j num_threads] [--batch-size=batch_size]
[--archive-timeout=timeout]
[--compress-algorithm=compression_algorithm]
[--compress-level=compression_level]
[remote_options] [logging_options]
```

Copies WAL files into the corresponding subdirectory of the backup catalog and validates the backup instance by `instance_name` and `system-identifier`. If parameters of the backup instance and the cluster do not match, this command fails with the following error message: Refuse to push WAL segment `segment_name` into archive. Instance parameters mismatch.

If the files to be copied already exists in the backup catalog, `go_probackup` computes and compares their checksums. If the checksums match, `archive-push` skips the corresponding file and returns a successful execution code. Otherwise, `archive-push` fails with an error. If you would like to replace WAL files in the case of checksum mismatch, run the `archive-push` command with the `--overwrite` flag.

Each file is copied to a temporary file with the `.part` suffix. If the temporary file already exists, `go_probackup` will wait `archive_timeout` seconds before discarding it. After the copy is done, atomic rename is performed. This algorithm ensures that a failed `archive-push` will not stall continuous archiving and that concurrent archiving from multiple sources into a single WAL archive has no risk of archive corruption.

To speed up archiving, you can specify the `--batch-size` option to copy WAL segments in batches of the specified size. If `--batch-size` option is used, then you can also specify the `-j` option to copy the batch of WAL segments on multiple threads.

WAL segments copied to the archive are synced to disk unless the `--no-sync` flag is used.

You can use `archive-push` in the `archive_command` Postgres Pro parameter to set up continuous WAL archiving.

For details, see sections Archiving Options and Compression Options.
Additional Supplied Programs

archive-get

```
pg_probackup archive-get -B backup_dir --instance instance_name --wal-file-path=wal_file_path --wal-file-name=wal_file_name
[-j num_threads] [--batch-size=batch_size]
[--prefetch-dir=prefetch_dir_path] [--no-validate-wal]
[--help] [remote_options] [logging_options]
```

Copies WAL files from the corresponding subdirectory of the backup catalog to the cluster's write-ahead log location. This command is automatically set by pg_probackup as part of the `restore_command` when restoring backups using a WAL archive. You do not need to set it manually.

To speed up recovery, you can specify the `--batch-size` option to copy WAL segments in batches of the specified size. If `--batch-size` option is used, then you can also specify the `-j` option to copy the batch of WAL segments on multiple threads.

For details, see section Archiving Options.

catchup

```
pg_probackup catchup -b catchup_mode
--source-pgdata=path_to_pgdata_on_remote_server
--destination-pgdata=path_to_local_dir
[--help] [-j | --threads=num_threads] [--stream]
[--temp-slot] [-P | --perm-slot] [-S | --slot=slot_name]
[--exclude-path=PATHNAME]
[-T OLDDIR=NEWDIR]
[connection_options] [remote_options]
```

Creates a copy of a Postgres Pro instance without using the backup catalog.

```
-b catchup_mode
--backup-mode=catchup_mode
```

Specifies the catchup mode to use. Possible values are:

- **FULL** — creates a full copy of the Postgres Pro instance.
- **DELTA** — reads all data files in the data directory and creates an incremental copy for pages that have changed since the destination instance was shut down.
- **PTRACK** — tracking page changes on the fly, only reads and copies pages that have changed since the point of divergence of the source and destination instances.

**Warning**

PTRACK catchup mode requires PTRACK not earlier than 2.0 and hence, Postgres Pro not earlier than 11.

```
--source-pgdata=path_to_pgdata_on_remote_server
```

Specifies the path to the data directory of the instance to be copied. The path can be local or remote.

```
--destination-pgdata=path_to_local_dir
```

Specifies the path to the local data directory to copy to.

```
-j num_threads
--threads=num_threads
```

Sets the number of parallel threads for catchup process.

```
--stream
```

Copies the instance in STREAM WAL delivery mode, including all the necessary WAL files by streaming them from the instance server via replication protocol.
-x=path_prefix
--exclude-path=path_prefix

Specifies a prefix for files to exclude from the synchronization of Postgres Pro instances during copying. The prefix must contain a path relative to the data directory of an instance. If the prefix specifies a directory, all files in this directory will not be synchronized.

**Warning**

This option is dangerous since excluding files from synchronization can result in incomplete synchronization; use with care.

--stream

Copies the instance in STREAM WAL delivery mode, including all the necessary WAL files by streaming them from the instance server via replication protocol.

--temp-slot

Creates a temporary physical replication slot for streaming WAL from the Postgres Pro instance being copied. It ensures that all the required WAL segments remain available if WAL is rotated while the backup is in progress. This flag can only be used together with the --stream flag and cannot be used together with the --perm-slot flag. The default slot name is pg_probackup_slot, which can be changed using the --slot/-S option.

-P
--perm-slot

Creates a permanent physical replication slot for streaming WAL from the Postgres Pro instance being copied. This flag can only be used together with the --stream flag and cannot be used together with the --temp-slot flag. The default slot name is pg_probackup_perm_slot, which can be changed using the --slot/-S option.

-S slot_name
--slot=slot_name

Specifies the replication slot for WAL streaming. This option can only be used together with the --stream flag.

-T OLDDIR=NEWDIR
--tablespace-mapping=OLDDIR=NEWDIR

Relocates the tablespace from the OLDDIR to the NEWDIR directory at the time of recovery. Both OLDDIR and NEWDIR must be absolute paths. If the path contains the equals sign (=), escape it with a backslash. This option can be specified multiple times for multiple tablespaces.

Additionally, connection options, remote mode options can be used.

For details on usage, see the section Cloning and Synchronizing Postgres Pro Instance.

**Options**

This section describes command-line options for pg_probackup commands. If the option value can be derived from an environment variable, this variable is specified below the command-line option, in the uppercase. Some values can be taken from the pg_probackup.conf configuration file located in the backup catalog.

For details, see the section called “Configuring pg_probackup”.

If an option is specified using more than one method, command-line input has the highest priority, while the pg_probackup.conf settings have the lowest priority.
Additional Supplied Programs

Common Options

The list of general options.

-B directory
--backup-path=directory
BACKUP_PATH

Specifies the absolute path to the backup catalog. Backup catalog is a directory where all backup files and meta information are stored. Since this option is required for most of the pg_probackup commands, you are recommended to specify it once in the BACKUP_PATH environment variable. In this case, you do not need to use this option each time on the command line.

-D directory
--pgdata=directory
PGDATA

Specifies the absolute path to the data directory of the database cluster. This option is mandatory only for the add-instance command. Other commands can take its value from the PGDATA environment variable, or from the pg_probackup.conf configuration file.

-i backup_id
--backup-id=backup_id

Specifies the unique identifier of the backup.

-j num_threads
--threads=num_threads
Sets the number of parallel threads for backup, restore, merge, validate, checkdb, and archive-push processes.

--progress
Shows the progress of operations.

--help
Shows detailed information about the options that can be used with this command.

Recovery Target Options

If continuous WAL archiving is configured, you can use one of these options together with restore or validate commands to specify the moment up to which the database cluster must be restored or validated.

--recovery-target=immediate|latest

Defines when to stop the recovery:

• The immediate value stops the recovery after reaching the consistent state of the specified backup, or the latest available backup if the -i/--backup-id option is omitted. This is the default behavior for STREAM backups.
• The latest value continues the recovery until all WAL segments available in the archive are applied. This is the default behavior for ARCHIVE backups.

--recovery-target-timeline=timeline

Specifies a particular timeline to be used for recovery. By default, the timeline of the specified backup is used.

--recovery-target-lsn=lsn

Specifies the LSN of the write-ahead log location up to which recovery will proceed. Can be used only when restoring a database cluster of major version 10 or higher.

--recovery-target-name=recovery_target_name

Specifies a named savepoint up to which to restore the cluster.
Additional Supplied Programs

--recovery-target-time=time
    Specifies the timestamp up to which recovery will proceed. If the time zone offset is not specified,
    the local time zone is used.

    Example: --recovery-target-time="2020-01-01 00:00:00+03"

--recovery-target-xid=xid
    Specifies the transaction ID up to which recovery will proceed.

--recovery-target-inclusive=boolean
    Specifies whether to stop just after the specified recovery target (true), or just before the recovery
    target (false). This option can only be used together with --recovery-target-name, --recovery-
    target-time, --recovery-target-lsn or --recovery-target-xid options. The default depends on
    the recovery_target_inclusive parameter.

    --recovery-target-action=pause|promote|shutdown
    Specifies recovery_target_action the server should take when the recovery target is reached.
    Default: pause

Retention Options

You can use these options together with backup and delete commands.

For details on configuring retention policy, see the section Configuring Retention Policy.

--retention-redundancy=redundancy
    Specifies the number of full backup copies to keep in the data directory. Must be a non-negative
    integer. The zero value disables this setting.

    Default: 0

--retention-window=window
    Number of days of recoverability. Must be a non-negative integer. The zero value disables this setting.

    Default: 0

--wal-depth=wal_depth
    Number of latest valid backups on every timeline that must retain the ability to perform PITR. Must
    be a non-negative integer. The zero value disables this setting.

    Default: 0

--delete-wal
    Deletes WAL files that are no longer required to restore the cluster from any of the existing backups.

--delete-expired
    Deletes backups that do not conform to the retention policy defined in the pg_probackup.conf
    configuration file.

--merge-expired
    Merges the oldest incremental backup that satisfies the requirements of retention policy with its
    parent backups that have already expired.

--dry-run
    Displays the current status of all the available backups, without deleting or merging expired backups,
    if any.
Pinning Options

You can use these options together with `backup` and `set-backup` commands.

For details on backup pinning, see the section **Backup Pinning**.

---

---*ttl=ttl*

Specifies the amount of time the backup should be pinned. Must be a non-negative integer. The zero value unpins the already pinned backup. Supported units: ms, s, min, h, d (s by default).

**Example:** `--ttl=30d`

---

---*expire-time=time*

Specifies the timestamp up to which the backup will stay pinned. Must be an ISO-8601 complaint timestamp. If the time zone offset is not specified, the local time zone is used.

**Example:** `--expire-time="2020-01-01 00:00:00+03"`

Logging Options

You can use these options with any command.

---

---*no-color*

Disable coloring for console log messages of **warning** and **error** levels.

---

---*log-level-console=log_level*

Controls which message levels are sent to the console log. Valid values are **verbose**, **log**, **info**, **warning**, **error**, and **off**. Each level includes all the levels that follow it. The later the level, the fewer messages are sent. The **off** level disables console logging.

Default: **info**

**Note**

All console log messages are going to stderr; so the output of **show** and **show-config** commands does not mingle with log messages.

---

---*log-level-file=log_level*

Controls which message levels are sent to a log file. Valid values are **verbose**, **log**, **info**, **warning**, **error**, and **off**. Each level includes all the levels that follow it. The later the level, the fewer messages are sent. The **off** level disables file logging.

Default: **off**

---

---*log-filename=log_filename*

Defines the filenames of the created log files. The filenames are treated as a **strftime** pattern, so you can use %-escapes to specify time-varying filenames.

Default: **pg_probackup.log**

For example, if you specify the `pg_probackup-%u.log` pattern, `pg_probackup` generates a separate log file for each day of the week, with %u replaced by the corresponding decimal number: `pg_probackup-1.log` for Monday, `pg_probackup-2.log` for Tuesday, and so on.

This option takes effect if file logging is enabled by the **--log-level-file** option.

---

---*error-log-filename=error_log_filename*

Defines the filenames of log files for error messages only. The filenames are treated as a **strftime** pattern, so you can use %-escapes to specify time-varying filenames.
Default: none

For example, if you specify the `error-pg_probackup-%u.log` pattern, `pg_probackup` generates a separate log file for each day of the week, with `%u` replaced by the corresponding decimal number: `error-pg_probackup-1.log` for Monday, `error-pg_probackup-2.log` for Tuesday, and so on.

This option is useful for troubleshooting and monitoring.

```bash
--log-directory=log_directory
```

Defines the directory in which log files will be created. You must specify the absolute path. This directory is created lazily, when the first log message is written.

Default: $BACKUP_PATH/log/

```bash
--log-rotation-size=log_rotation_size
```

Maximum size of an individual log file. If this value is reached, the log file is rotated once a `pg_probackup` command is launched, except `help` and `version` commands. The zero value disables size-based rotation. Supported units: kB, MB, GB, TB (kB by default).

Default: 0

```bash
--log-rotation-age=log_rotation_age
```

Maximum lifetime of an individual log file. If this value is reached, the log file is rotated once a `pg_probackup` command is launched, except `help` and `version` commands. The time of the last log file creation is stored in `$BACKUP_PATH/log/log_rotation`. The zero value disables time-based rotation. Supported units: ms, s, min, h, d (min by default).

Default: 0

### Connection Options

You can use these options together with `backup`, `catchup`, and `checkdb` commands.

All `libpq` environment variables are supported.

```bash
-d dbname
```

Specifies the name of the database to connect to. The connection is used only for managing backup process, so you can connect to any existing database. If this option is not provided on the command line, `PGDATABASE` environment variable, or the `pg_probackup.conf` configuration file, `pg_probackup` tries to take this value from the `PGUSER` environment variable, or from the current user name if `PGUSER` variable is not set.

```bash
-h host
```

Specifies the host name of the system on which the server is running. If the value begins with a slash, it is used as a directory for the Unix domain socket.

Default: localhost

```bash
-p port
```

Specifies the TCP port or the local Unix domain socket file extension on which the server is listening for connections.
Additional Supplied Programs

Default: 5432

-\texttt{U \ username}
-\texttt{pguser=\ username}
\texttt{PGUSER}

User name to connect as.

-\texttt{w}
-\texttt{no-password}

Disables a password prompt. If the server requires password authentication and a password is not available by other means such as a \texttt{.pgpass} file or \texttt{PGPASSWORD} environment variable, the connection attempt will fail. This flag can be useful in batch jobs and scripts where no user is present to enter a password.

-\texttt{W}
-\texttt{password}

Forces a password prompt. (Deprecated)

Compression Options

You can use these options together with \texttt{backup} and \texttt{archive-push} commands.

-\texttt{compress-algorithm=\ compression\_algorithm}

Defines the algorithm to use for compressing data files. Possible values are zlib, pglz, and none. If set to zlib or pglz, this option enables compression. By default, compression is disabled. For the \texttt{archive-push} command, the pglz compression algorithm is not supported.

Default: none

-\texttt{compress-level=\ compression\_level}

Defines compression level (0 through 9, 0 being no compression and 9 being best compression). This option can be used together with the \texttt{compress-algorithm} option.

Default: 1

-\texttt{compress}

Alias for \texttt{compress-algorithm=zlib} and \texttt{compress-level=1}.

Archiving Options

These options can be used with the \texttt{archive-push} command in the \texttt{archive\_command} setting and the \texttt{archive-get} command in the \texttt{restore\_command} setting.

Additionally, remote mode options and logging options can be used.

-\texttt{wal-file-path=\ wal\_file\_path}

Provides the path to the WAL file in \texttt{archive\_command} and \texttt{restore\_command}. Use the \texttt{%p} variable as the value for this option or explicitly specify the path to a file outside of the data directory. If you skip this option, the path specified in \texttt{pg\_probackup\_conf} will be used.

-\texttt{wal-file-name=\ wal\_file\_name}

Provides the name of the WAL file in \texttt{archive\_command} and \texttt{restore\_command}. Use the \texttt{%f} variable as the value for this option for correct processing. If the value of \texttt{wal-file-path} is a path outside of the data directory, explicitly specify the filename.

-\texttt{overwrite}

Overwrites archived WAL file. Use this flag together with the \texttt{archive-push} command if the specified subdirectory of the backup catalog already contains this WAL file and it needs to be replaced with
its newer copy. Otherwise, `archive-push` reports that a WAL segment already exists, and aborts the operation. If the file to replace has not changed, `archive-push` skips this file regardless of the `--overwrite` flag.

```
--batch-size=batch_size
```

Sets the maximum number of files that can be copied into the archive by a single `archive-push` process, or from the archive by a single `archive-get` process.

```
--archive-timeout=wait_time
```

Sets the timeout for considering existing `.part` files to be stale. By default, `pg_probackup` waits 300 seconds. This option can be used only with `archive-push` command.

```
--no-ready-rename
```

Do not rename status files in the `archive_status` directory. This option should be used only if `archive_command` contains multiple commands. This option can be used only with `archive-push` command.

```
--no-sync
```

Do not sync copied WAL files to disk. You can use this flag to speed up archiving process. Using this flag can result in WAL archive corruption in case of operating system or hardware crash. This option can be used only with `archive-push` command.

```
--prefetch-dir=path
```

Directory used to store prefetched WAL segments if `--batch-size` option is used. Directory must be located on the same filesystem and on the same mountpoint the `PGDATA/pg_wal` is located. By default files are stored in `PGDATA/pg_wal/pbk_prefetch` directory. This option can be used only with `archive-get` command.

```
--no-validate-wal
```

Do not validate prefetched WAL file before using it. Use this option if you want to increase the speed of recovery. This option can be used only with `archive-get` command.

**Remote Mode Options**

This section describes the options related to running `pg_probackup` operations remotely via SSH. These options can be used with `add-instance`, `set-config`, `backup`, `catchup`, `restore`, `archive-push`, and `archive-get` commands.

For details on configuring and using the remote mode, see the section called “Configuring the Remote Mode” and the section called “Using `pg_probackup` in the Remote Mode”.

```
--remote-proto=proto
```

Specifies the protocol to use for remote operations. Currently only the SSH protocol is supported. Possible values are:

- `ssh` enables the remote mode via SSH. This is the default value.
- `none` explicitly disables the remote mode.

You can omit this option if the `--remote-host` option is specified.

```
--remote-host=destination
```

Specifies the remote host IP address or hostname to connect to.

```
--remote-port=port
```

Specifies the remote host port to connect to.

Default: 22
**Additional Supplied Programs**

```plaintext
--remote-user=username
   Specifies remote host user for SSH connection. If you omit this option, the current user initiating
   the SSH connection is used.

--remote-path=path
   Specifies pg_probackup installation directory on the remote system.

--ssh-options=ssh_options
   Provides a string of SSH command-line options. For example, the following options can be
   used to set keep-alive for SSH connections opened by pg_probackup: --ssh-options="-o ServerAliveCountMax=5 -o ServerAliveInterval=60". For the full list of possible options, see

### Remote WAL Archive Options

This section describes the options used to provide the arguments for [remote mode options](#) in `archive-get` used in the `restore_command` command when restoring ARCHIVE backups or performing PITR.

```plaintext
--archive-host=destination
   Provides the argument for the `--remote-host` option in the `archive-get` command.

--archive-port=port
   Provides the argument for the `--remote-port` option in the `archive-get` command.
   **Default:** 22

--archive-user=username
   Provides the argument for the `--remote-user` option in the `archive-get` command. If you omit this
   option, the user that has started the Postgres Pro cluster is used.
   **Default:** Postgres Pro user
```

### Incremental Restore Options

This section describes the options for incremental cluster restore. These options can be used with the `restore` command.

```plaintext
-I incremental_mode
   --incremental-mode=incremental_mode
   Specifies the incremental mode to be used. Possible values are:
   - CHECKSUM — replace only pages with mismatched checksum and LSN.
   - LSN — replace only pages with LSN greater than point of divergence.
   - NONE — regular restore.
```

### Partial Restore Options

This section describes the options for partial cluster restore. These options can be used with the `restore` command.

```plaintext
--db-exclude=dbname
   Specifies the name of the database to exclude from restore. All other databases in the cluster will be
   restored as usual, including template0 and template1. This option can be specified multiple times
   for multiple databases.

--db-include=dbname
   Specifies the name of the database to restore from a backup. All other databases in the cluster will not
   be restored, with the exception of template0 and template1. This option can be specified multiple
   times for multiple databases.
```
Replica Options

This section describes the options related to taking a backup from standby.

Note

Starting from pg_probackup 2.0.24, backups can be taken from standby without connecting to the master server, so these options are no longer required. In lower versions, pg_probackup had to connect to the master to determine recovery time — the earliest moment for which you can restore a consistent state of the database cluster.

--master-db=dbname

Deprecated. Specifies the name of the database on the master server to connect to. The connection is used only for managing the backup process, so you can connect to any existing database. Can be set in the pg_probackup.conf using the set-config command.

Default: postgres, the default Postgres Pro database

--master-host=host

Deprecated. Specifies the host name of the system on which the master server is running.

--master-port=port

Deprecated. Specifies the TCP port or the local Unix domain socket file extension on which the master server is listening for connections.

Default: 5432, the Postgres Pro default port

--master-user=username

Deprecated. User name to connect as.

Default: postgres, the Postgres Pro default user name

--replica-timeout=timeout

Deprecated. Wait time for WAL segment streaming via replication, in seconds. By default, pg_probackup waits 300 seconds. You can also define this parameter in the pg_probackup.conf configuration file using the set-config command.

Default: 300 sec

How-To

All examples below assume the remote mode of operations via SSH. If you are planning to run backup and restore operation locally, skip the “Setup passwordless SSH connection” step and omit all --remote-* options.

Examples are based on Ubuntu 18.04, Postgres Pro 11, and pg_probackup 2.2.0.

• backup — Postgres Pro role used for connection to Postgres Pro cluster.
• backupdb — database used for connection to Postgres Pro cluster.
• backup_host — host with backup catalog.
• backupman — user on backup_host running all pg_probackup operations.
• /mnt/backups — directory on backup_host where backup catalog is stored.
• postgres_host — host with Postgres Pro cluster.
• postgres — user on postgres_host that has started the Postgres Pro cluster.
• /var/lib/postgresql/11/main — Postgres Pro data directory on postgres_host.
Minimal Setup

This scenario illustrates setting up standalone FULL and DELTA backups.

1. **Set up passwordless SSH connection from** `backup_host` **to** `postgres_host`:
   ```
   [backupman@backup_host] ssh-copy-id postgres@postgres_host
   ```

2. **Configure your Postgres Pro cluster.**
   For security purposes, it is recommended to use a separate database for backup operations.
   ```
   postgres=#
   CREATE DATABASE backupdb;
   ```
   Connect to the `backupdb` database, create the `probackup` role, and grant the following permissions to this role:
   ```
   backupdb=#
   BEGIN;
   CREATE ROLE backup WITH LOGIN REPLICATION;
   GRANT USAGE ON SCHEMA pg_catalog TO backup;
   GRANT EXECUTE ON FUNCTION pg_catalog.current_setting(text) TO backup;
   GRANT EXECUTE ON FUNCTION pg_catalog.set_config(text, text, boolean) TO backup;
   GRANT EXECUTE ON FUNCTION pg_catalog.pg_is_in_recovery() TO backup;
   GRANT EXECUTE ON FUNCTION pg_catalog.pg_start_backup(text, boolean, boolean) TO backup;
   GRANT EXECUTE ON FUNCTION pg_catalog.pg_stop_backup(boolean, boolean) TO backup;
   COMMIT;
   ```

3. **Initialize the backup catalog:**
   ```
   [backupman@backup_host]$ pg_probackup-11 init -B /mnt/backups
   INFO: Backup catalog '/mnt/backups' successfully inited
   ```

4. **Add instance `pg-11` to the backup catalog:**
   ```
   [backupman@backup_host]$ pg_probackup-11 add-instance -B /mnt/backups --
   instance pg-11 --remote-host=postgres_host --remote-user=postgres -D /var/lib/
   postgresql/11/main
   INFO: Instance 'node' successfully inited
   ```

5. **Take a FULL backup:**
   ```
   [backupman@backup_host] pg_probackup-11 backup -B /mnt/backups --instance pg-11
   --stream --remote-host=postgres_host --remote-user=postgres -U backup -d
   ```
   ```
   INFO: Backup start, pg_probackup version: 2.2.0, instance: node, backup ID: PZ7YK2, 
   backup mode: FULL, wal mode: STREAM, remote: true, compress-algorithm: none, 
   compress-level: 1
   INFO: Start transferring data files
   INFO: Data files are transferred
   INFO: wait for pg_stop_backup()
   INFO: pg_stop backup() successfully executed
   INFO: Validating backup PZ7YK2
   INFO: Backup PZ7YK2 data files are valid
   INFO: Backup PZ7YK2 resident size: 196MB
   ```
INFO: Backup PZ7YK2 completed

6. **Let's take a look at the backup catalog:**

```bash
[backupman@backup_host] pg_probackup-11 show -B /mnt/backups --instance pg-11
```

```
BACKUP INSTANCE 'pg-11'
==================================================================================================================================
Instance Version ID      Recovery Time           Mode   WAL Mode  TLI  Time
Data   WAL  Zratio  Start LSN  Stop LSN   Status
==================================================================================================================================
node      11       PZ7YK2  2019-10-11 19:45:45+03  FULL  STREAM    1/0   11s
180MB  16MB    1.00  0/3C000028  0/3C000198  OK
```

7. **Take an incremental backup in the DELTA mode:**

```bash
[backupman@backup_host] pg_probackup-11 backup -B /mnt/backups --instance pg-11 -b delta --stream --remote-host=postgres_host --remote-user=postgres -U backup -d backupdb
```

INFO: Backup start, pg_probackup version: 2.2.0, instance: node, backup ID: PZ7YMP, backup mode: DELTA, wal mode: STREAM, remote: true, compress-algorithm: none, compress-level: 1
INFO: Parent backup: PZ7YK2
INFO: Start transferring data files
INFO: Data files are transferred
INFO: wait for pg_stop_backup()
INFO: pg_stop backup() successfully executed
INFO: Validating backup PZ7YMP
INFO: Backup PZ7YMP data files are valid
INFO: Backup PZ7YMP resident size: 32MB
INFO: Backup PZ7YMP completed

8. **Let's add some parameters to pg_probackup configuration file, so that you can omit them from the command line:**

```bash
[backupman@backup_host] pg_probackup-11 set-config -B /mnt/backups --instance pg-11 --remote-host=postgres_host --remote-user=postgres -U backup -d backupdb
```

9. **Take another incremental backup in the DELTA mode, omitting some of the previous parameters:**

```bash
[backupman@backup_host] pg_probackup-11 backup -B /mnt/backups --instance pg-11 -b delta --stream
```

INFO: Backup start, pg_probackup version: 2.2.0, instance: node, backup ID: PZ7YR5, backup mode: DELTA, wal mode: STREAM, remote: true, compress-algorithm: none, compress-level: 1
INFO: Parent backup: PZ7YMP
INFO: Start transferring data files
INFO: Data files are transferred
INFO: wait for pg_stop_backup()
INFO: pg_stop backup() successfully executed
INFO: Validating backup PZ7YR5
INFO: Backup PZ7YR5 data files are valid
INFO: Backup PZ7YR5 resident size: 32MB
INFO: Backup PZ7YR5 completed

10. **Let's take a look at the instance configuration:**

```bash
[backupman@backup_host] pg_probackup-11 show-config -B /mnt/backups --instance pg-11
```

```
# Backup instance information
pgdata = /var/lib/postgresql/11/main
```
system-identifier = 6746586934060931492
xlog-seg-size = 16777216
# Connection parameters
pgdatabase = backupdb
pghost = postgres_host
pguser = backup
# Replica parameters
replica-timeout = 5min
# Archive parameters
archive-timeout = 5min
# Logging parameters
log-level-console = INFO
log-level-file = OFF
log-filename = pg_probackup.log
log-rotation-size = 0
log-rotation-age = 0
# Retention parameters
retention-redundancy = 0
retention-window = 0
wal-depth = 0
# Compression parameters
compress-algorithm = none
compress-level = 1
# Remote access parameters
remote-proto = ssh
remote-host = postgres_host

Note that we are getting the default values for other options that were not overwritten by the set-config command.

11. Let's take a look at the backup catalog:

[backupman@backup_host] pg_probackup-11 show -B /mnt/backups --instance pg-11

Versioning

pg_probackup follows semantic versioning.

Authors

Postgres Professional, Moscow, Russia.

Credits

pg_probackup utility is based on pg_arman, which was originally written by NTT and then developed and maintained by Michael Paquier.
pg_repack

pg_repack — utility and Postgres Pro Standard extension to reorganize tables

Synopsis

pg_repack [option...] [dbname]

Description

pg_repack is a Postgres Pro Standard extension which lets you remove bloat from tables and indexes, and optionally restore the physical order of clustered indexes. Unlike CLUSTER and VACUUM FULL it works online, without holding an exclusive lock on the processed tables during processing. pg_repack is efficient to boot, with performance comparable to using CLUSTER directly.

pg_repack is a fork of the previous http://reorg.projects.pgfoundry.org/ project. Please check the https://github.com/reorg/pg_repack for bug report and development information.

You can choose one of the following methods to reorganize data:

• Online CLUSTER (ordered by cluster index)
• Ordering by specified columns
• Online VACUUM FULL (packing rows only)
• Rebuild or relocate only the indexes of a table

Note

Only superusers can use the utility.

Note

Target table must have a PRIMARY KEY, or at least a UNIQUE total index on a NOT NULL column.

Installation

On Linux systems, pg_repack is provided together with Postgres Pro as a separate pre-built package and requires the postgrespro-std-14-server package to be installed with all the dependencies. For the list of available packages and detailed installation instructions, see Chapter 16. On Windows systems, pg_repack is automatically installed as part of Postgres Pro.

Once you have pg_repack installed, load the pg_repack extension in the database you want to process, as follows:

$ psql -c "CREATE EXTENSION pg_repack" -d your_database

You can later remove pg_repack from a Postgres Pro installation using DROP EXTENSION pg_repack.

If you are upgrading from a previous version of pg_repack, just drop the old version from the database as explained above and install the new version.

Options

Reorganization Options

- a
  --all

Attempt to repack all the databases of the cluster. Databases where the pg_repack extension is not installed will be skipped.
Additional Supplied Programs

-t table
--table=table

Reorganize the specified table(s) only. Multiple tables may be reorganized by writing multiple -t switches. By default, all eligible tables in the target databases are reorganized.

-c schema
--schema=schema

Repack the tables in the specified schema(s) only. Multiple schemas may be repacked by writing multiple -c switches. Can be used in conjunction with --tablespace to move tables to a different tablespace.

-o column[, ...]
--order-by=column[, ...]

Perform an online CLUSTER ordered by the specified columns.

-n
--no-order

Perform an online VACUUM FULL. Since version 1.2 this is the default for non-clustered tables.

-N
--dry-run

Show what would be repacked and exit.

-j num_jobs
--jobs=num_jobs

Create the specified number of extra connections to Postgres Pro Standard, and use these extra connections to parallelize the rebuild of indexes on each table. Parallel index builds are only supported for full-table repacks, not with --index or --only-indexes options. If your server has extra cores and disk I/O available, this can be a useful way to speed up pg_repack.

-s tablespace
--tablespace=tablespace

Move the repacked tables to the specified tablespace: essentially an online version of ALTER TABLE ... SET TABLESPACE. The tables' indexes are left in the original tablespace unless --moveidx is specified too.

-S
--moveidx

Also move the indexes of the repacked tables to the tablespace specified by the --tablespace option.

-i index
--index=index

Repack the specified index(es) only. Multiple indexes may be repacked by writing multiple -i switches. May be used in conjunction with --tablespace to move the index(es) to a different tablespace.

-x
--only-indexes

Repack only the indexes of the specified table(s), which must be specified with the --table option.

-T secs
--wait-timeout=secs

pg_repack needs to take an exclusive lock at the end of the reorganization. This setting controls how many seconds pg_repack will wait to acquire this lock. If the lock cannot be taken after this duration,
pg_repack will forcibly cancel the conflicting queries. If you are using Postgres Pro or PostgreSQL version 8.4 or newer, pg_repack will fall back to using `pg_terminate_backend()` to disconnect any remaining backends after this timeout has passed twice. The default is 60 seconds.

-\z
--no-analyze

Disable `ANALYZE` after a full-table reorganization. If not specified, `ANALYZE` is executed after the reorganization.

**Connection Options**

-\[d\] `dbname`
-\(--dbname=\) `dbname`

Specifies the name of the database to be reorganized. If this is not specified and -a (or --all) is not used, the database name is read from the environment variable `PGDATABASE`. If that is not set, the user name specified for the connection is used.

-\h `host`
-\(--host=\) `host`

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

-\p `port`
-\(--port=\) `port`

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

-\U `username`
-\(--username=\) `username`

User name to connect as.

-\w
-\(--no-password\)

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

-\W
-\(--password\)

Force pg_repack to prompt for a password before connecting to a database.

This option is never essential, since pg_repack will automatically prompt for a password if the server demands password authentication. However, pg_repack will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing -w to avoid the extra connection attempt.

**Generic Options**

-\e
-\(--echo\)

Echo the commands that pg_repack generates and sends to the server.

-\E level
-\(--elevel=\) `level`

Choose the output message level from `DEBUG`, `INFO`, `NOTICE`, `WARNING`, `ERROR`, `LOG`, `FATAL`, and `PANIC`. The default is `INFO`.

2564
Additional Supplied Programs

--help
   Show help about pg_repack command line arguments, and exit.

-V
--version
   Print the pg_repack version and exit.

Environment

PGDATABASE
PGHOST
PGPORT
PGUSER

Default connection parameters

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by libpq (see Section 32.15).

Examples

Perform an online CLUSTER of all the clustered tables in the database test, and perform an online VACUUM FULL of all the non-clustered tables:

$ pg_repack test

Perform an online VACUUM FULL on the tables foo and bar in the database test (an eventual cluster index is ignored):

$ pg_repack --no-order --table foo --table bar test

Move all indexes of table foo to tablespace tbs:

$ pg_repack -d test --table foo --only-indexes --tablespace tbs

Move the specified index to tablespace tbs:

$ pg_repack -d test --index idx --tablespace tbs

Diagnostics

Error messages are reported when pg_repack fails. The following list shows the cause of errors.

You need to cleanup by hand after fatal errors. To cleanup, just remove pg_repack from the database and install it again.

For Postgres Pro or PostgreSQL 9.1 and newer execute:

DROP EXTENSION pg_repack CASCADE
in the database where the error occurred, followed by

CREATE EXTENSION pg_repack

For previous versions load the script $SHAREDIR/contrib/uninstall_pg_repack.sql into the database where the error occurred and then load $SHAREDIR/contrib/pg_repack.sql again.

INFO: database "db" skipped:
pg_repack VER is not installed in the database:
pg_repack is not installed in the database when the --all option is specified.

Create the pg_repack extension in the database.
Additional Supplied Programs

ERROR: pg_repack VER is not installed in the database:
pg_repack is not installed in the database specified by --dbname

Create the pg_repack extension in the database.

ERROR: program 'pg_repack V1' does not match database library 'pg_repack V2':
There is a mismatch between the pg_repack binary and the database library (.so or .dll).

The mismatch could be due to the wrong binary in the PATH or the wrong database being addressed. Check the program directory and the database; if they are what expected you may need to repeat pg_repack installation.

ERROR: extension 'pg_repack V1' required, found extension 'pg_repack V2':
The SQL extension found in the database does not match the version required by the pg_repack program.

You should drop the extension from the database and reload it as described in the section called "Installation".

ERROR: relation "table" must have a primary key or not-null unique keys:
The target table doesn't have a PRIMARY KEY or any UNIQUE constraints defined.

Define a PRIMARY KEY or a UNIQUE constraint on the table.

ERROR: query failed: ERROR: column "col" does not exist:
The target table doesn't have columns specified by --order-by option.

Specify existing columns.

WARNING: the table "tbl" already has a trigger called z_repack_trigger:
The trigger was probably installed during a previous attempt
to run pg_repack on the table which was interrupted
and for some reason failed to clean up the temporary objects.

You can remove all the temporary objects by dropping and re-creating the extension: see the section called "Installation" for the details.

WARNING: trigger "trg" conflicting on table "tbl":
The target table has a trigger whose name follows z_repack_trigger
in alphabetical order.

The z_repack_trigger should be the last BEFORE trigger to fire. Please rename your trigger so that it sorts alphabetically before pg_repack one; you can use:

ALTER TRIGGER zzz_my_trigger
  ON sometable RENAME TO yyy_my_trigger;
ERROR: Another pg_repack command may be running on the table. Please try again later.

There is a chance of deadlock when two concurrent pg_repack commands are run on the same table. So, try to run the command after some time.

WARNING: Cannot create index "schema"."index_xxxxx", already exists
DETAIL: An invalid index may have been left behind by a previous pg_repack on the table which was interrupted. Please use DROP INDEX "schema"."index_xxxxx" to remove this index and try again.

A temporary index apparently created by pg_repack has been left behind, and we do not want to risk dropping this index ourselves. If the index was in fact created by an old pg_repack job which didn't get cleaned up, you should just use DROP INDEX and try the repack command again.

Restrictions

pg_repack comes with the following restrictions.

Temporary tables

pg_repack cannot reorganize temporary tables.

GiST indexes

pg_repack cannot reorganize tables using GiST indexes.

DDL commands

You will not be able to perform DDL commands of the target table(s) except VACUUM or ANALYZE while pg_repack is working. pg_repack will hold an ACCESS SHARE lock on the target table during a full-table repack, to enforce this restriction.

If you are using version 1.1.8 or earlier, you must not attempt to perform any DDL commands on the target table(s) while pg_repack is running. In many cases pg_repack would fail and rollback correctly, but there were some cases in these earlier versions which could result in data corruption.

clusterdb, vacuumdb
vacuumlo

vacuumlo — remove orphaned large objects from a Postgres Pro database

Synopsis

vacuumlo [option...] dbname...

Description

vacuumlo is a simple utility program that will remove any “orphaned” large objects from a Postgres Pro database. An orphaned large object (LO) is considered to be any LO whose OID does not appear in any oid or lo data column of the database.

If you use this, you may also be interested in the lo_manage trigger in the lo module. lo_manage is useful to try to avoid creating orphaned LOs in the first place.

All databases named on the command line are processed.

Options

vacuumlo accepts the following command-line arguments:

- -l limit
--limit=limit

Remove no more than limit large objects per transaction (default 1000). Since the server acquires a lock per LO removed, removing too many LOs in one transaction risks exceeding max_locks_per_transaction. Set the limit to zero if you want all removals done in a single transaction.

- -n
--dry-run

Don't remove anything, just show what would be done.

- -v
--verbose

Write a lot of progress messages.

- -V
--version

Print the vacuumlo version and exit.

- -?
--help

Show help about vacuumlo command line arguments, and exit.

vacuumlo also accepts the following command-line arguments for connection parameters:

- -h host
--host=host

Database server's host.

- -p port
--port=port

Database server's port.
Additional Supplied Programs

-\( U \) \texttt{username}  
  \texttt{--username=username}

  User name to connect as.

-\( w \)  
  \texttt{--no-password}

  Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a .\texttt{pgpass} file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

-\( W \)  
  \texttt{--password}

  Force vacuumlo to prompt for a password before connecting to a database.

  This option is never essential, since vacuumlo will automatically prompt for a password if the server demands password authentication. However, vacuumlo will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing \texttt{--no-password} to avoid the extra connection attempt.

Environment

\texttt{PGHOST}  
\texttt{PGPORT}  
\texttt{PGUSER}

  Default connection parameters.

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by libpq (see Section 32.15).

The environment variable \texttt{PG\_COLOR} specifies whether to use color in diagnostic messages. Possible values are \texttt{always}, \texttt{auto} and \texttt{never}.

Notes

vacuumlo works by the following method: First, vacuumlo builds a temporary table which contains all of the OIDs of the large objects in the selected database. It then scans through all columns in the database that are of type \texttt{oid} or \texttt{lo}, and removes matching entries from the temporary table. (Note: Only types with these names are considered; in particular, domains over them are not considered.) The remaining entries in the temporary table identify orphaned LOs. These are removed.

Author

Peter Mount \texttt{<peter@retep.org.uk>}

G.2. Server Applications

This section covers Postgres Pro Standard server-related applications. They are typically run on the host where the database server resides. See also Postgres Pro Server Applications for information about server applications that are part of the core Postgres Pro Standard distribution.
mamonsu — a monitoring agent for collecting Postgres Pro and system metrics.

Synopsis

mamonsu agent [agent_action]
mamonsu bootstrap -M mamonsu_user [-c | --config] [-x | --create-extensions] [connection_options]
mamonsu export {template | config} filename [export_options]
mamonsu report [report_options] [connection_options]
mamonsu tune [tuning_options] [connection_options]
mamonsu upload [upload_options]
mamonsu zabbix {template | host | hostgroup} server_action
mamonsu zabbix item {error | lastvalue | lastclock} host_id
mamonsu zabbix version
mamonsu --version
mamonsu --help

Description

mamonsu is a monitoring agent for collecting Postgres Pro and system metrics that can be visualized on the Zabbix server. Unlike the native Zabbix Agent configured to collect Postgres Pro metrics, mamonsu uses a single database connection, which allows to minimize performance impact on the monitored system.

The mamonsu agent includes the following components:

• A supervisor process that monitors database and system activity.
• Plugins that specify which Postgres Pro and system metrics to collect.
• Customizable configuration and template files that define which plugins to use and how to visualize the collected data.

mamonsu is an active agent, which means that it sends the data to the Zabbix server once it is collected. Pre-configured to monitor multiple Postgres Pro and system metrics out of the box, mamonsu can be extended with your own custom plugins to track other metrics critical for your system.

mamonsu also provides the command-line interface for updating some Zabbix server settings, as well as getting an overview of the monitored system configuration and tuning Postgres Pro and system settings on the fly. You can find the list of all mamonsu commands in the section called “Command-Line Reference”.

Installation and Setup

Important

Before you start installation, attentively read Compatibility Considerations.
To use mamonsu, you must create a Zabbix account and set up a Zabbix server as explained in Zabbix documentation. Naturally, you must also have a Postgres Pro instance up and running if you are going to monitor Postgres Pro metrics. If you are configuring your Postgres Pro cluster from scratch, see Chapter 16 and Section 17.2 for Postgres Pro installation and setup instructions, respectively.

**Note**

While mamonsu can collect Postgres Pro metrics from a remote cluster, system metrics are only collected locally. If you choose to collect Postgres Pro metrics remotely, make sure to disable collection of system metrics to avoid confusion, as they will be displayed under the same host in Zabbix.

A pre-built mamonsu package is provided together with Postgres Pro Standard, but has a separate installer. Once you have installed mamonsu, complete the following steps to set up metrics collection:

1. **Optionally, bootstrap mamonsu**
   
   If you omit this step, metrics can only be collected on behalf of a superuser, which is not recommended.

   In this step, the bootstrap command sets the mamonsu user, creates mamonsu schema in the specified or implied database, as well as extensions and objects needed for monitoring.

   bootstrap has no mandatory options. When run without options, it takes the values needed from the configuration file (/etc/mamonsu/agent.conf by default). Below is a simple example of bootstrap:

   1. In the [postgres] section of agent.conf, specify connection parameters for the Postgres Pro cluster you are going to monitor. For more details, see Connection Parameters.
   2. Run the following command to bootstrap mamonsu:
      
      ```bash
      mamonsu bootstrap
      ```

      This command will create the user mamonsu with the password mamonsu, create monitoring functions in the database specified in agent.conf and grant the right to execute them to the mamonsu user.

   In the following example, bootstrap options are passed explicitly.

   1. Create a non-privileged database user for mamonsu. For example:
      
      ```sql
      CREATE USER mamonsu_user WITH PASSWORD 'mamonsu_password';
      ```
   2. Create a database that will be used for connection to Postgres Pro. For example:
      
      ```sql
      CREATE DATABASE mamonsu_database OWNER mamonsu_user;
      ```
   3. Run the following command to bootstrap mamonsu:
      
      ```bash
      mamonsu bootstrap -M mamonsu_user -x -c /etc/mamonsu/mamonsu.conf -d mamonsu_database -U postgres --host myhost --port 5432
      ```

      For details of the options -M, -x and -c, see bootstrap. For details of other options, see Connection Options. This command will create monitoring functions in the mamonsu_database and grant the right to execute them to mamonsu_user. The pg_buffercache extension will also be created to ensure collection of metrics on the shared buffer cache, and the path to the configuration file will be changed.

   As a result, a superuser connection is no longer required. Note that mamonsu also creates several tables in the mamonsu schema in the specified database. Do not delete these tables as they are required for mamonsu to work.

2. **Configure mamonsu**

   Edit the agent.conf configuration file, which is located in the /etc/mamonsu/ directory by default.
• Configure Zabbix-related settings. The address field must point to the running Zabbix server, while the client field must provide the name of the Zabbix host. You can find the list of hosts available for your account in the Zabbix web interface under Configuration > Hosts.

```ini
[zabbix]
; enabled by default
enabled = True
client = zabbix_host_name
address = zabbix_server
```

• By default, mamonsu will collect both Postgres Pro and system metrics. If required, you can disable metrics collection of either type by setting the enabled parameter to False in the [postgres] or [system] section of the agent.conf file, respectively.

```ini
[system]
; enabled by default
enabled = True
```

**Note**

While mamonsu can collect Postgres Pro metrics from a remote cluster, system metrics are only collected locally. If you choose to collect Postgres Pro metrics remotely, make sure to disable collection of system metrics to avoid confusion, as they will be displayed under the same host in Zabbix.

• If you are going to collect Postgres Pro metrics, specify connection parameters for the Postgres Pro cluster you are going to monitor. In the user, password, and database fields, you must specify the mamonsu_user, mamonsu_password, and the mamonsu_database used for bootstrap, respectively. If you skipped the bootstrap, specify superuser credentials and the database to connect to.

```ini
[postgres]
; enabled by default
enabled = True
user = mamonsu_user
database = mamonsu_database
password = mamonsu_password
port = 5432
```

These are the main mamonsu settings to get started. You can also fine-tune other mamonsu settings as explained in the section called “Configuration Parameters”.

3. **Configure how to display metrics on the Zabbix server**

1. Generate a template that defines how to visualize the collected metrics on the Zabbix server:

   mamonsu export template template.xml

   mamonsu generates the template.xml file in your current directory. By default, the name of the template that will be displayed in the Zabbix account is PostgresPro-OS, where OS is the name of your operating system. To get a template with a different display name, you can run the above command with the --template-name option.

2. Optionally, specify your Zabbix account settings in the following environment variables on your monitoring system:

   • Set the ZABBIX_USER and ZABBIX_PASSWD variables to the login and password of your Zabbix account, respectively.

   • Set the ZABBIX_URL to http://zabbix/
If you skip this step, you will have to add the following options to all `mamonsu zabbix` commands that you run:

```
--url=http://zabbix/ --user=zabbix_login --password=zabbix_password
```

3. Upload `template.xml` to the Zabbix server.

```
mamonsu zabbix template export template.xml
```

Alternatively, you can upload the template through the Zabbix web interface: log in to your Zabbix account and select **Templates > Import**.

4. Link the generated template to the host to be monitored.

In the Zabbix web interface, select your host, go to **Templates > Add**, select your template, and click **Update**.

---

**Tip**

If you would like to link a template with a new Zabbix host, you can do it from the command line using `mamonsu zabbix` commands. See the section called “Managing Zabbix Server Settings from the Command Line” for details.

---

When the setup is complete, start `mamonsu`. For example, on Linux systems, you can start `mamonsu` as a service with the following command:

```
service mamonsu start
```

`mamonsu` picks up all the parameters from the `mamonsu` configuration file and starts monitoring your system.

**Command-Line Reference**

**agent**

Syntax:

```
mamonsu agent { metric-list | metric-get metric_name | version }
```

Provides information on the collected metrics from the command line. You can specify one of the following parameters:

- **metric-list**
  
  Show the list of metrics that `mamonsu` is collecting. The output of this command provides the item key of each metric, its latest value, and the time when this value was received.

- **metric-get metric_name**
  
  Check the latest value for the specified metric. You can get the list of available metrics using the `metric-list` option.

- **version**
  
  Display `mamonsu` version.

**bootstrap**

Syntax:

```
mamonsu bootstrap -M mamonsu_user
  [-c config_file | --config config_file]
  [-x | --create-extensions] [connection_options]
```
Bootstrap mamonsu. This command can take the following options:

-M
    Specify a non-privileged user that will own all mamonsu processes.

-c config_file
    config=config_file

Specify the agent.conf file where the [postgres] section contains the database name to be used if --dbname is not specified through connection_options.

Default: /etc/mamonsu/agent.conf

-x
    --create-extensions

Create auxiliary extensions. Only pg_buffercache will be currently created, which is no longer created by default.

collection_connection

Provide optional command-line connection parameters.

export

Syntax:

mamonsu export config filename.conf [--add-plugins=plugin_directory]
mamonsu export template filename.xml [--add-plugins=plugin_directory]
    [--template-name=template_name]
    [--application=application_name]
    [--old-zabbix]

Generate a template or configuration file for metrics collection. The optional parameters to customize metrics collection are as follows:

--add-plugins=plugin_directory
    Collect metrics that are defined in custom plugins located in the specified plugin_directory. If you are going to use custom plugins, you must provide this option when generating both the configuration file and the template.

--template-name=template_name
    Specify the name of the template that will be displayed on the Zabbix server.

Default: PostgresPro-OS, where OS is the name of your operating system

--application=application_name
    Specify an identifier under which the collected metrics will be displayed on the Zabbix server.

Default: App-PostgresPro-OS, where OS is the name of your operating system

--old-zabbix
    Export a template for Zabbix server version 4.2 or lower. By default, the template is generated in a format compatible with Zabbix 4.4 or higher.

export zabbix-parameters

Syntax:

mamonsu export zabbix-parameters filename.conf [--add-plugins=plugin_directory]
Export metrics configuration for use with the native Zabbix agent. The optional parameters to customize metrics collection are as follows:

--add-plugins=plugin_directory

Collect metrics that are defined in custom plugins located in the specified plugin_directory. If you are going to use custom plugins, you must provide this option when generating both the configuration file and the template.

--plugin-type={pg | sys | all}

Specify the type of metrics to collect:
• pg for Postgres Pro metrics.
• sys for system metrics.
• all for both Postgres Pro and system metrics.

Default: all

--pg-version=version

Specify the major version of the server for which to configure metrics collection. mamonsu can collect metrics for all supported Postgres Pro versions, as well as PostgreSQL versions starting from 9.5.

Default: 10

--config=config_file

Specify the agent.conf file to be used as the source for metrics definitions.

Default: /etc/mamonsu/agent.conf

export zabbix-template

Syntax:

mamonsu export zabbix-template filename.conf [--add-plugins=plugin_directory]

[--plugin-type={pg | sys | all}]
[--template-name=template_name]
[--application=application_name]
[--config=config_file]
[--old-zabbix]

Export a template for use with the native Zabbix agent. The optional parameters to customize metrics collection are as follows:

--add-plugins=plugin_directory

Collect metrics that are defined in custom plugins located in the specified plugin_directory. If you are going to use custom plugins, you must provide this option when generating both the configuration file and the template.

--plugin-type={pg | sys | all}

Specify the type of metrics to collect:
• pg configures Postgres Pro metrics.
• sys configures system metrics.
• all configures both Postgres Pro and system metrics.
Additional Supplied Programs

Default: all

--template-name=template_name

Specify the name of the template that will be displayed on the Zabbix server.

Default: PostgresPro-OS, where OS is the name of your operating system

--application=application_name

Specify an identifier under which the collected metrics will be displayed on the Zabbix server.

Default: App-PostgresPro-OS, where OS is the name of your operating system

--config=config_file

Specify the agent.conf file to be used as the source for metrics definitions.

Default: /etc/mamonsu/agent.conf

--old-zabbix

Export a template for Zabbix server version 4.2 or lower. By default, the template is generated in a format compatible with Zabbix 4.4 or higher.

report

Syntax:

mamonsu report [--run-system=Boolean] [--run-postgres=Boolean]
               [--print-report=Boolean] [--report-path=report_file]
               [--disable-sudo] [connection_options]

Generate a detailed report on the hardware, operating system, memory usage and other parameters of the monitored system, as well as Postgres Pro configuration.

The following optional parameters customize the report:

--run-system=Boolean

Include system information into the generated report.

Default: True

--run-postgres=Boolean

Include information on Postgres Pro into the generated report.

Default: True

--print-report=Boolean

Print the report to stdout.

Default: True

--report-path=report_file

Save the report into the specified file.

Default: /tmp/report.txt

--disable-sudo

Do not report data that can only be received with superuser rights. This option is only available for Linux systems.
connection_options

Provide optional command-line connection parameters.

tune
Syntax:
mamonsu tune [--dry-run] [--disable-sudo] [--log-level {INFO|DEBUG|WARN}]
               [--dont-tune-pgbadger] [--dont-reload-postgresql]
               [connection_options]

Optimize Postgres Pro and system configuration based on the collected statistics. You can use the following options:

--dry-run
Display the settings to be tuned without changing the actual system and Postgres Pro configuration.

--disable-sudo
Do not tune the settings that can only be changed by a superuser. This option is only available for Linux systems.

--dont-tune-pgbadger
Do not tune pgbadger parameters.

--log-level { INFO | DEBUG | WARN}
Change the logging level.

Default: INFO

--dont-reload-postgresql
Forbid mamonsu to run the pg_reload_conf() function. If you specify this option, the modified settings that require reloading Postgres Pro configuration do not take effect immediately.

connection_options

Provide optional command-line connection parameters.

upload
Syntax:
mamonsu upload [--zabbix-file=metrics_file]
               [--zabbix-address=zabbix_address] [--zabbix-port=port_number]
               [--zabbix-client=zabbix_host_name] [--zabbix-log-level={INFO|DEBUG|WARN}]

Upload metrics data previously saved into a file onto a Zabbix server for visualization. For details on how to save metrics into a file, see the section called “Logging Parameters”.

This command can take the following options:

--zabbix-address=zabbix_address
The address of the Zabbix server.

Default: localhost

--zabbix-port=port_number
The port of the Zabbix server.
Additional Supplied Programs

Default: 10051

--zabbix-file=metrics_file

A text file that stores the collected metrics data to be visualized, such as localhost.log.

--zabbix-client=zabbix_host_name

The name of the Zabbix host.

Default: localhost

--zabbix-log-level={INFO|DEBUG|WARN}

Change the logging level.

Default: INFO

zabbix item

Syntax:

mamonsu zabbix item {error | lastvalue | lastclock} host_name

View the specified property of the latest metrics data received by Zabbix for the specified host.

zabbix version

Syntax:

mamonsu zabbix version

Get the version of the Zabbix server that mamonsu is connected to.

zabbix host

Syntax:

mamonsu zabbix host list
mamonsu zabbix host show host_name
mamonsu zabbix host id host_name
mamonsu zabbix host delete host_id
mamonsu zabbix host create host_name hostgroup_id template_id mamonsu_address
mamonsu zabbix host info {templates | hostgroups | graphs | items} host_id

Manage Zabbix hosts using one of the actions described in the section called “Zabbix Server Actions”.

zabbix hostgroup

Syntax:

mamonsu zabbix hostgroup list
mamonsu zabbix hostgroup show hostgroup_name
mamonsu zabbix hostgroup id hostgroup_name
mamonsu zabbix hostgroup delete hostgroup_id
mamonsu zabbix hostgroup create hostgroup_name

Manage Zabbix host groups using one of the actions described in the section called “Zabbix Server Actions”.

zabbix template

Syntax:

mamonsu zabbix template list
mamonsu zabbix template show template_name
mamonsu zabbix template id template_name
mamonsu zabbix template delete template_id
mamonsu zabbix template export file

Manage Zabbix templates using one of the actions described in the section called “Zabbix Server Actions”.

--version
Syntax:
    mamonsu --version
Display mamonsu version.

--help
Syntax:
    mamonsu --help
Display mamonsu command-line help.

Connection Options

connection_options provide command-line connection parameters for the target Postgres Pro cluster. connection_options can be --host, --port, --dbname (-d), --username (-U), and --password (-W). The --dbname option should specify the mamonsu_database created for monitoring purposes. Note that the --username (-U) option must specify a superuser that can access the cluster.

If you omit connection_options, mamonsu checks the configuration file for the needed settings. Make sure to provide the actual connection parameters if your Postgres Pro cluster is located elsewhere.

Zabbix Server Actions

Using mamonsu, you can control some of the Zabbix server functionality from the command line. Specifically, you can create or delete Zabbix hosts and host groups, as well as generate, import, and delete Zabbix templates using one of the following commands. The object_name to use must correspond to the type of the Zabbix object specified in the command: template, host, or hostgroup.

list
    Display the list of available templates, hosts, or host groups.

show object_name
    Display the details about the specified template, host, or host group.

id object_name
    Show the ID of the specified object, which is assigned automatically by the Zabbix server.

delete object_id
    Delete the object with the specified ID.

create hostgroup_name
create host_name hostgroup_id template_id mamonsu_address
    Create a new host or a host group.

export template_name
    Generate a Zabbix template.

info {templates | hostgroups | graphs | items} host_id
    Display detailed information about the templates, host groups, graphs, and metrics available on the host with the specified ID.
Configuration Parameters

The `agent.conf` configuration file is located in the `/etc/mamonsu` directory by default. It provides several groups of parameters that control which metrics to collect and how to log the collected data:

- connection parameters
- logging parameters
- plugin parameters

All parameters must be specified in the `parameter = value` format.

Connection Parameters

`[postgres]`

The `[postgres]` section controls Postgres Pro metrics collection and can contain the following parameters:

enabled

Enables/disables Postgres Pro metrics collection if set to `True` or `False`, respectively.

**Default:** `True`

user

The user on behalf of which the cluster will be monitored. It must be the mamonsu user set in bootstrap, or a superuser if bootstrap was not run.

**Default:** `postgres`

password

The password for the specified user.

database

The database to connect to for metrics collection.

**Default:** `postgres`

host

The server address to connect to.

**Default:** `localhost`

port

The port to connect to.

**Default:** `5432`

application_name

Application name that identifies mamonsu connected to the Postgres Pro cluster.

**Default:** `mamonsu`

query_timeout

`statement_timeout` for the mamonsu session, in seconds. If a Postgres Pro metric query does not complete within this time interval, it gets terminated.

**Default:** `10`
Additional Supplied Programs

[system]
The [system] section controls system metrics collection and can contain the following parameters:

enabled
   Enables/disables system metrics collection if set to True or False, respectively.
   Default: True

[zabbix]
The [zabbix] section provides connection settings for the Zabbix server and can contain the following parameters:

enabled
   Enables/disables sending the collected metrics data to the Zabbix server if set to True or False, respectively.
   Default: True

client
   The name of the Zabbix host.

address
   The address of the Zabbix server.
   Default: 127.0.0.1

port
   The port of the Zabbix server.
   Default: 10051

[agent]
The [agent] section specifies the location of mamonsu and whether it is allowed to access metrics from the command line:

enabled
   Enables/disables metrics collection from the command line using the agent command.
   Default: True

host
   The address of the system on which mamonsu is running.
   Default: 127.0.0.1

port
   The port on which mamonsu is running.
   Default: 10052

[sender]
The [sender] section controls the queue size of the data to be sent to the Zabbix server:

queue
   The maximum number of collected metric values that can be accumulated locally before mamonsu sends them to the Zabbix server. Once the accumulated data is sent, the queue is cleared.

2581
**Logging Parameters**

**[metric_log]**

The [metric_log] section enables storing the collected metrics data in text files locally. This section can contain the following parameters:

**enabled**

Enables/disables storing the collected metrics data in a text file. If this option is set to True, mamonsu creates the `localhost.log` file for storing metric values.

Default: False

**directory**

Specifies the directory where log files with metrics data will be stored.

Default: /var/log/mamonsu

**max_size_mb**

The maximum size of a log file, in MB. When the specified size is reached, it is renamed to `localhost.log.archive`, and an empty `localhost.log` file is created.

Default: 1024

**[log]**

The [log] section specifies logging settings for mamonsu and can contain the following parameters:

**file**

Specifies the log filename, which can be preceded by the full path.

**level**

Specifies the debug level. This option can take DEBUG, ERROR, or INFO values.

Default: INFO

**format**

The format of the logged data.

Default: [%(levelname)s] %(asctime)s - %(name)s - %(message)s

where `levelname` is the debug level, `asctime` returns the current time, `name` specifies the plugin that emitted this log entry or root otherwise, and `message` provides the actual log message.

**Plugin Parameters**

**[plugins]**

The [plugins] section specifies custom plugins to be added for metrics collection and can contain the following parameters:

**enabled**

Enables/disables using custom plugins for metrics collection if set to True or False, respectively.

Default: False

**directory**

Specifies the directory that contains custom plugins for metrics collection. Setting this parameter to None forbids using custom plugins.
Additional Supplied Programs

Default: /etc/mamonsu/plugins

If you need to configure any of the plugins you add to mamonsu after installation, you have to add this plugin section to the agent.conf file.

The syntax of this section should follow the syntax used with the examples shown below in the section called “Individual Plugin Sections”.

Individual Plugin Sections

All built-in plugins are installed along with mamonsu. To configure a built-in plugin you should find a corresponding section below the Individual Plugin Sections heading and edit its parameter values.

To disable any plugin you should set the enabled parameter to False and to enable it — set it to True. These values are case sensitive.

The example below shows individual plugin sections corresponding to the preparedtransaction and the pgprobackup built-in plugins:

```
[preparedtransaction]
max_prepared_transaction_time = 60
interval = 60

[pgprobackup]
enabled = false
interval = 300
backup_dirs = /backup_dir1,/backup_dir2
pg_probackup_path = /usr/bin/pg_probackup-11
```

[preparedtransaction]

This plugin gets age in seconds of the oldest prepared transaction and number of all transactions prepared for a two-phase commit. For additional information refer to PREPARE TRANSACTION and Section 50.80.

The max_prepared_transaction_time parameter specifies the threshold in seconds for the age of the prepared transaction.

The interval parameter allows you to change the metrics collection interval.

The plugin collects two metrics: pgsql.prepared.count (number of prepared transactions) and pgsql.prepared.oldest (oldest prepared transaction age in seconds).

If pgsql.prepared.oldest value exceeds the threshold specified by the max_prepared_transaction_time parameter, a trigger with the following message is fired: "PostgreSQL prepared transaction is too old on {host}".

[pgprobackup]

This plugin uses pg_probackup to track its backups’ state and gets size of backup directories which store all backup files.

Please note that this plugin counts the total size of all files in the target directory. Make sure that extraneous files are not stored in this directory.

The backup_dirs parameter specifies a comma-separated list of paths to directories for which metrics should be collected.

The pg_probackup_path parameter specifies the path to pg_probackup.

The interval parameter allows you to change the metrics collection interval.

By default this plugin is disabled. To enable it set the enabled parameter to True.
Additional Supplied Programs

This plugin collects two metrics: 
pg_probackup.dir.size[#backup_directory] (the size of the target directory) and 
pg_probackup.dir.error[#backup_directory] (backup errors) for each specified backup_directory.

If any generated backup has bad status, like ERROR, CORRUPT, ORPHAN, a trigger is fired.

Usage

Collecting and Viewing Metrics Data

Once started, mamonsu begins collecting system and Postgres Pro metrics. The agent command enables you to get an overview of the collected metrics from the command line in real time.

To view the list of available metrics, use the agent metric-list command:

mamonsu agent metric-list

The output of this command provides the item key of each metric, its latest value, and the time when this value was received. For example:

system.memory[active] 7921004544 1564570818
system.memory[swap_cache] 868352 1564570818
pgsql.connections[idle] 6.0 1564570818
pgsql.archive_command[failed_trying_to_archive] 0 1564570818

To view the current value for a specific metric, you can use the agent metric-get command:

mamonsu agent metric-get metric_name

where metric_name is the item key of the metric to monitor, as returned by the metric-list command. For example, pgsq1.connections[idle].

You can view graphs for the collected metrics in the Zabbix web interface under the Graphs menu. For details on working with Zabbix, see its official documentation at https://www.zabbix.com/documentation/current/.

If you have chosen to save all the collected metrics data into a file, as explained in the section called “Logging Parameters”, you can later upload these metrics onto a Zabbix server for visualization using the upload command.

Adding Custom Plugins

You can extend mamonsu with your own custom plugins, as follows:

1. Save all custom plugins in a single directory, such as /etc/mamonsu/plugins.
2. Make sure this directory is specified in your configuration file under the [plugins] section:

   [plugins]
directory = /etc/mamonsu/plugins

3. Generate a new Zabbix template to include custom plugins:

   mamonsu export template template.xml --add-plugins=/etc/mamonsu/plugins

4. Upload the generated template.xml to the Zabbix server as explained in the section called “Installation and Setup”.

Tuning Postgres Pro and System Configuration

Based on the collected metrics data, mamonsu can tune your Postgres Pro and system configuration for optimal performance.

You can get detailed information about the hardware, operating system, memory usage and other parameters of the monitored system, as well as Postgres Pro configuration, as follows:

mamonsu report
To view the suggested optimizations without applying them, run the `tune` command with the `--dry-run` option:

```
mamonsu tune --dry-run
```

To apply all the suggested changes, run the `tune` command without any parameters:

```
mamonsu tune
```

You can exclude some settings from the report or disable some of the optimizations by passing optional parameters. See the section called “Command-Line Reference” for the full list of parameters available for `report` and `tune` commands.

**Managing Zabbix Server Settings from the Command Line**

Mamonsu enables you to work with the Zabbix server from the command line. You can upload template files to Zabbix, create and delete Zabbix hosts and host groups, link templates with hosts and check the latest metric values.

To set up your Zabbix host from scratch, you can follow these steps:

1. Optionally, specify your Zabbix account settings in the following environment variables on your monitoring system:

   • Set the `ZABBIX_USER` and `ZABBIX_PASSWD` variables to the login and password of your Zabbix account, respectively.

   • Set the `ZABBIX_URL` to `http://zabbix/`

   If you skip this step, you will have to add the following options to all `mamonsu` `zabbix` commands that you run:

   ```
   --url=http://zabbix/ --user=zabbix_login --password=zabbix_password
   ```

2. Generate a new template file and upload it to the Zabbix server:

   ```
mamonsu export template template.xml
mamonsu zabbix template export template.xml
```

3. Create a new host group:

   ```
mamonsu zabbix hostgroup create hostgroup_name
```

4. Check the IDs for this host group and the uploaded template, which are assigned automatically by the Zabbix server:

   ```
mamonsu zabbix hostgroup id hostgroup_name
mamonsu zabbix template id template_name
```

5. Create a host associated with this group and link it with the uploaded template using a single command:

   ```
mamonsu zabbix host create host_name hostgroup_id template_id mamonsu_address
```

   where `host_name` is the name of the host, `hostgroup_id` and `template_id` are the unique IDs returned in the previous step, and `mamonsu_address` is the IP address of the system on which mamonsu runs.

Once your Zabbix host is configured, complete the setup of your monitoring system as explained in the section called “Installation and Setup”.

**Exporting Metrics for Native Zabbix Agent**

Using mamonsu, you can convert system and Postgres Pro metrics definitions to the format supported by the native Zabbix agent.

This feature currently has the following limitations:
You cannot export metrics if you run `mamonsu` on Windows systems.

Metrics definitions for `pg_wait_sampling` and CFS features available in Postgres Pro Enterprise are not converted.

To collect metrics provided by mamonsu using the native Zabbix agent, do the following:

1. Generate a configuration file that is compatible with the native Zabbix agent and place it under `/etc/zabbix/zabbix_agent.d/`. You can prepend the filename with the required path:
   ```bash
   mamonsu export zabbix-parameters /etc/zabbix/zabbix_agent.d/zabbix_agent.conf
   ```
   For all possible options of the `export zabbix-parameters` command, see the section called “Command-Line Reference”.

2. Generate a template for the native Zabbix agent:
   ```bash
   mamonsu export zabbix-template template.xml
   ```
   For all possible options of the `export zabbix-template` command, see the section called “Command-Line Reference”.

3. Upload the generated template to the Zabbix server, as explained in the section called “Installation and Setup”.

4. If you are going to collect Postgres Pro metrics, change the following macros in the template after the upload:
   - For `{PG_CONNINFO}`, provide connection parameters for the Postgres Pro server to be monitored.
   - For `{PG_PATH}`, specify psql installation directory.

**Compatibility Considerations**

If you want to upgrade mamonsu to a version that is not compatible with the previous one, what you must do to continue using the application depends on whether you need to retain the metrics data collected.

1. If you need to retain the collected data, do the following:
   1. Install the new version of mamonsu.
   2. Generate a new template for the Zabbix server.
   3. If you performed a bootstrap using the previous version of mamonsu, run the `bootstrap` command again.
   4. Upload the new template to the Zabbix server.
   5. Rename the host for which you want to retain the collected data and leave the old template linked to that host.
   6. Create a new host for the same system and link the new template to it.
   7. Restart mamonsu. It will collect data for the new host. The old host will no longer be used, but the data collected will be available.

2. If you do not need to retain the collected data, do the following:
   1. Install the new version of mamonsu.
   2. Generate a new template for the Zabbix server.
   3. If you performed a bootstrap using the previous version of mamonsu, run the `bootstrap` command again.
   4. Upload the new template to the Zabbix server.
   5. In the settings of the Zabbix host, link the new template to the host instead of the old one.
   6. Restart mamonsu. It will start collecting data. All the data collected earlier will be lost.
**pgbouncer**

pgbouncer — a Postgres Pro connection pooler

**Synopsis**

On Linux systems:

```
pgbouncer [-d] [-R] [-v] [-u user] pgbouncer.ini
pgbouncer -V | -h
```

On Windows systems:

```
pgbouncer [-v] [-u user] pgbouncer.ini
pgbouncer -V | -h
```

To use pgbouncer as a Windows service:

```
pgbouncer.exe --regservice pgbouncer.ini
pgbouncer.exe --unregservice pgbouncer.ini
```

**Description**

pgbouncer is a Postgres Pro connection pooler. Any target application can be connected to pgbouncer as if it were a Postgres Pro server, and pgbouncer will create a connection to the actual server, or it will reuse one of its existing connections.

The aim of pgbouncer is to lower the performance impact of opening new connections to Postgres Pro.

In order not to compromise transaction semantics for connection pooling, pgbouncer supports several types of pooling when rotating connections:

**Session pooling**

Most polite method. When a client connects, a server connection will be assigned to it for the whole duration the client stays connected. When the client disconnects, the server connection will be put back into the pool. This is the default method.

**Transaction pooling**

A server connection is assigned to a client only during a transaction. When pgbouncer notices that transaction is over, the server connection will be put back into the pool.

**Statement pooling**

Most aggressive method. The server connection will be put back into the pool immediately after a query completes. Multi-statement transactions are disallowed in this mode as they would break.

The administration interface of pgbouncer consists of some new `SHOW` commands available when connected to a special “virtual” database `pgbouncer`.

**Quick Start**

Basic setup and usage is as follows.

1. Create a `pgbouncer.ini` file. Details in the `pgbouncer(5)` man page. Simple example:

   ```ini
   [databases]
template1 = host=127.0.0.1 port=5432 dbname=template1
   ```
[pgbouncer]
listen_port = 6543
listen_addr = 127.0.0.1
auth_type = md5
auth_file = userlist.txt
logfile = pgbouncer.log
pidfile = pgbouncer.pid
admin_users = someuser

2. Create a userlist.txt file that contains the users allowed in:

"someuser" "same_password_as_in_server"

3. Launch pgbouncer:

$ pgbouncer -d pgbouncer.ini

Note

The above command does not work on Windows systems. Instead, pgbouncer must be launched as a service that first needs to be registered, as follows:

pgbouncer --regservice

4. Have your application (or the psql client) connect to pgbouncer instead of directly to the Postgres Pro server:

$ psql -p 6543 -U someuser template1

5. Manage pgbouncer by connecting to the special administration database pgbouncer and issuing SHOW HELP; to begin:

$ psql -p 6543 -U someuser pgbouncer
pgbouncer=# SHOW HELP;
NOTICE:  Console usage
DETAIL:
SHOW [HELP|CONFIG|DATABASES|FDS|POOLS|CLIENTS|SERVERS|SOCKETS|LISTS|VERSION|...]
SET key = arg
RELOAD
PAUSE
SUSPEND
RESUME
SHUTDOWN
[...]

6. If you made changes to the pgbouncer.ini file, you can reload it with:

pgbouncer=# RELOAD;

Options

-d
Run in the background. Without it, the process will run in the foreground.

Note

Does not work on Windows, pgbouncer needs to run as service there.
Additional Supplied Programs

- \texttt{R}
  Do an online restart. That means connecting to the running process, loading the open sockets from it, and then using them. If there is no active process, boot normally.

\begin{center}
\textbf{Note}
Works only if OS supports Unix sockets and the \texttt{unix_socket_dir} is not disabled in configuration. Does not work on Windows. Does not work with TLS connections, they are dropped.
\end{center}

- \texttt{u user}
  Switch to the given user on startup.

- \texttt{v}
  Increase verbosity. Can be used multiple times.

- \texttt{q}
  Be quiet: do not log to \texttt{stdout}. This does not affect logging verbosity, only that \texttt{stdout} is not to be used. For use in \texttt{init.d} scripts.

- \texttt{V}
  Show version.

- \texttt{h}
  Show short help.

--regservice
  Win32: Register to run as Windows service. The \texttt{service_name} configuration parameter value is used as the name to register under.

--unregservice
  Win32: Unregister Windows service.

\textbf{Admin Console}

The console is available by connecting as normal to the database pgbouncer:

\$ psql -p 6543 pgbouncer

Only users listed in the configuration parameters \texttt{admin_users} or \texttt{stats_users} are allowed to log in to the console. (Except when \texttt{auth_mode=any}, then any user is allowed in as a \texttt{stats_user}.)

Additionally, the user name \texttt{pgbouncer} is allowed to log in without password, if the login comes via the Unix socket and the client has same Unix user uid as the running process.

\textbf{Show Commands}

The \texttt{SHOW} commands output information. Each command is described below.

\textbf{SHOW STATS}

Shows statistics. In this and related commands, the total figures are since process start, the averages are updated every \texttt{stats_period}.

\begin{verbatim}
database
  Statistics are presented per database.
\end{verbatim}
Additional Supplied Programs

- **total_xact_count**: Total number of SQL transactions pooled by pgbouncer.
- **total_query_count**: Total number of SQL queries pooled by pgbouncer.
- **total_received**: Total volume in bytes of network traffic received by pgbouncer.
- **total_sent**: Total volume in bytes of network traffic sent by pgbouncer.
- **total_xact_time**: Total number of microseconds spent by pgbouncer when connected to Postgres Pro in a transaction, either idle in transaction or executing queries.
- **total_query_time**: Total number of microseconds spent by pgbouncer when actively connected to Postgres Pro, executing queries.
- **total_wait_time**: Time spent by clients waiting for a server, in microseconds.
- **avg_xact_count**: Average transactions per second in last stat period.
- **avg_query_count**: Average queries per second in last stat period.
- **avg_recv**: Average received (from clients) bytes per second.
- **avg_sent**: Average sent (to clients) bytes per second.
- **avg_xact_time**: Average transaction duration, in microseconds.
- **avg_query_time**: Average query duration, in microseconds.
- **avg_wait_time**: Time spent by clients waiting for a server, in microseconds (average per second).

**SHOW STATS TOTALS**
Subset of **SHOW STATS** showing the total values (**total_**).

**SHOW STATS AVERAGES**
Subset of **SHOW STATS** showing the average values (**avg_**).

**SHOW TOTALS**
Like **SHOW STATS** but aggregated across all databases.
SHOW SERVERS

type
   S, for server.

user
   User name pgbouncer uses to connect to server.

database
   Database name.

state
   State of the pgbouncer server connection, one of active, used or idle.

addr
   IP address of Postgres Pro server.

port
   Port of Postgres Pro server.

local_addr
   Connection start address on local machine.

local_port
   Connection start port on local machine.

connect_time
   When the connection was made.

request_time
   When last request was issued.

wait
   Current waiting time in seconds.

wait_us
   Microsecond part of the current waiting time.

close_needed
   1 if the connection will be closed as soon as possible, because a configuration file reload or DNS update changed the connection information or RECONNECT was issued.

ptr
   Address of internal object for this connection. Used as unique ID.

link
   Address of client connection the server is paired with.

remote_pid
   PID of backend server process. In case connection is made over Unix socket and OS supports getting process ID info, its OS PID. Otherwise it's extracted from cancel packet the server sent, which should
be the PID in case the server is Postgres Pro, but it’s a random number in case the server is another pgbouncer.

tls
A string with TLS connection information, or empty if not using TLS.

SHOW CLIENTS

type
C, for client.

user
Client connected user.

database
Database name.

state
State of the client connection, one of active, used, waiting or idle.

addr
IP address of client.

port
Port client is connected to.

local_addr
Connection end address on local machine.

local_port
Connection end port on local machine.

connect_time
Timestamp of connect time.

request_time
Timestamp of latest client request.

wait
Current waiting time in seconds.

wait_us
Microsecond part of the current waiting time.

close_needed
Not used for clients.

ptr
Address of internal object for this connection. Used as unique ID.

link
Address of server connection the client is paired with.
remote_pid
   Process ID, in case client connects over Unix socket and OS supports getting it.

tls
   A string with TLS connection information, or empty if not using TLS.

SHOW POOLS
   A new pool entry is made for each couple of (database, user).

database
   Database name.

user
   User name.

cl_active
   Client connections that are linked to server connection and can process queries.

cl_waiting
   Client connections have sent queries but have not yet got a server connection.

sv_active
   Server connections that linked to a client.

sv_idle
   Server connections that are unused and immediately usable for client queries.

sv_used
   Server connections that have been idle for more than server_check_delay, so they need server_check_query to run on them before they can be used again.

sv_tested
   Server connections that are currently running either server_reset_query or server_check_query.

sv_login
   Server connections currently in the process of logging in.

maxwait
   How long the first (oldest) client in the queue has waited, in seconds. If this starts increasing, then the current pool of servers does not handle requests quickly enough. The reason may be either an overloaded server or just too small of a pool_size setting.

maxwait_us
   Microsecond part of the maximum waiting time.

pool_mode
   The pooling mode in use.

SHOW LISTS
   Show following internal information, in columns (not rows):

databases
   Count of databases.
Additional Supplied Programs

users
  Count of users.

pools
  Count of pools.

free_clients
  Count of free clients.

used_clients
  Count of used clients.

login_clients
  Count of clients in login state.

free_servers
  Count of free servers.

used_servers
  Count of used servers.

dns_names
  Count of DNS names in the cache.

dns_zones
  Count of DNS zones in the cache.

dns_queries
  Count of in-flight DNS queries.

dns_pending
  Not used.

SHOW USERS

name
  The user name.

pool_mode
  The user's override pool_mode, or NULL if the default will be used instead.

SHOW DATABASES

name
  Name of configured database entry.

host
  Host pgbouncer connects to.

port
  Port pgbouncer connects to.

database
  Actual database name pgbouncer connects to.
force_user
When the user is part of the connection string, the connection between pgbouncer and Postgres Pro is forced to the given user, whatever the client user.

pool_size
Maximum number of server connections.

reserve_pool
Maximum number of additional connections for this database.

pool_mode
The database’s override pool_mode, or NULL if the default will be used instead.

max_connections
Maximum number of allowed connections for this database, as set by max_db_connections, either globally or per database.

current_connections
Current number of connections for this database.

paused
1 if this database is currently paused, else 0.

disabled
1 if this database is currently disabled, else 0.

SHOW FDS
Internal command — shows list of file descriptors (FDs) in use with internal state attached to them.

When the connected user has the user name pgbouncer, connects through the Unix socket and has the same UID as the running process, the actual FDs are passed over the connection. This mechanism is used to do an online restart.

Note
This does not work on Windows systems.

This command also blocks the internal event loop, so it should not be used while pgbouncer is in use.

fd
File descriptor numeric value.

task
One of pooler, client or server.

user
User of the connection using the FD.

database
Database of the connection using the FD.

addr
IP address of the connection using the FD, unix if a Unix socket is used.
**Show Sockets, Show Active Sockets**

Shows low-level information about sockets or only active sockets. This includes the information shown under **Show Clients** and **Show Servers** as well as other more low-level information.

**Show Config**

Shows the current configuration settings, one per row, with the following columns:

- **Key**
  Configuration variable name.
- **Value**
  Configuration value.
- **Changeable**
  Either yes or no, shows if the variable can be changed while running. If no, the variable can be changed only at boot-time. Use **set** to change a variable at run time.

**Show Mem**

Shows low-level information about the current sizes of various internal memory allocations. The information presented is subject to change.

**Show DNS Hosts**

Show host names in DNS cache.

- **Hostname**
  Host name.
- **TTL**
  How many seconds until next lookup.
- **Addrs**
  Comma separated list of addresses.

**Show DNS Zones**

Show DNS zones in cache.

- **Zonename**
  Zone name.
- **Serial**
  Current serial.
- **Count**
  Host names belonging to this zone.
Additional Supplied Programs

**Process Controlling Commands**

**PAUSE [db]**

pgbouncer tries to disconnect from all servers, first waiting for all queries to complete. The command will not return before all queries are finished. To be used at the time of database restart.

If database name is given, only that database will be paused.

New client connections to a paused database will wait until RESUME is called.

**DISABLE db**

Reject all new client connections on the given database.

**ENABLE db**

Allow new client connections after a previous **DISABLE command**.

**RECONNECT db**

Close each open server connection for the given database, or all databases, after it is released (according to the pooling mode), even if its lifetime is not up yet. New server connections can be made immediately and will connect as necessary according to the pool size settings.

This command is useful when the server connection setup has changed, for example to perform a gradual switchover to a new server. It is not necessary to run this command when the connection string in pgbouncer.ini has been changed and reloaded (see **RELOAD**) or when DNS resolution has changed, because then the equivalent of this command will be run automatically. This command is only necessary if something downstream of pgbouncer routes the connections.

After this command is run, there could be an extended period where some server connections go to an old destination and some server connections go to a new destination. This is likely only sensible when switching read-only traffic between read-only replicas, or when switching between nodes of a multimaster replication setup. If all connections need to be switched at the same time, **PAUSE** is recommended instead. To close server connections without waiting (for example, in emergency failover rather than gradual switchover scenarios), also consider **KILL**.

**KILL db**

Immediately drop all client and server connections on given database.

New client connections to a killed database will wait until RESUME is called.

**SUSPEND**

All socket buffers are flushed and pgbouncer stops listening for data on them. The command will not return before all buffers are empty. To be used at the time of pgbouncer online reboot.

New client connections to a suspended database will wait until RESUME is called.

**RESUME [db]**

Resume work from previous **KILL, PAUSE, or SUSPEND command**.

**SHUTDOWN**

The pgbouncer process will exit.

**RELOAD**

The pgbouncer process will reload its configuration file and update changeable settings.

PgBouncer notices when a configuration file reload changes the connection parameters of a database definition. An existing server connection to the old destination will be closed when the server connection is next released (according to the pooling mode), and new server connections will immediately use the updated connection parameters.
**WAIT_CLOSE [db]**

Wait until all server connections, either of the specified database or of all databases, have cleared the close_needed state (see the section called “SHOW SERVERS”). This can be called after a RECONNECT or RELOAD to wait until the respective configuration change has been fully activated, for example in switchover scripts.

**Other Commands**

**SET key = arg**

Changes a configuration setting (see also the section called “SHOW CONFIG”). For example:

```
SET log_connections = 1;
SET server_check_query = 'select 2';
```

(Note that this command is run on the pgbouncer admin console and sets pgbouncer settings. A SET command run on another database will be passed to the Postgres Pro backend like any other SQL command.)

**Signals**

**SIGHUP**

Reload config. Same as issuing the command RELOAD on the console.

**SIGINT**

Safe shutdown. Same as issuing PAUSE and SHUTDOWN on the console.

**SIGTERM**

Immediate shutdown. Same as issuing SHUTDOWN on the console.

**SIGUSR1**

Same as issuing PAUSE on the console.

**SIGUSR2**

Same as issuing RESUME on the console.

**Libevent Settings**

From the libevent documentation:

It is possible to disable support for epoll, kqueue, devpoll, poll, or select by setting the environment variable EVENT_NOEPOLL, EVENT_NOKQUEUE, EVENTNODEVPOLL, EVENT_NOPOLL or EVENT_NODESELECT, respectively.

By setting the environment variable EVENT SHOW METHOD, libevent displays the kernel notification method that it uses.

**pgbouncer.ini Configuration File**

The configuration file is in the .ini format. Section names are between "[" and "]". Lines starting with ";" or "#" are taken as comments and ignored. The characters ";" and ";#" are not recognized when they appear later in the line.

**Generic Settings**

**logfile**

Specifies log file. Log file is kept open so after rotation kill -HUP or on console RELOAD; should be done. Note: On Windows systems, the service must be stopped and started.

Default: not set
Additional Supplied Programs

pidfile
    Specifies the PID file. Without a pidfile, daemonization is not allowed.
    Default: not set

listen_addr
    Specifies list of addresses, where to listen for TCP connections. You may also use * meaning "listen on all addresses". When not set, only Unix socket connections are allowed.
    Addresses can be specified numerically (IPv4/IPv6) or by name.
    Default: not set

listen_port
    Which port to listen on. Applies to both TCP and Unix sockets.
    Default: 6432

unix_socket_dir
    Specifies location for Unix sockets. Applies to both listening socket and server connections. If set to an empty string, Unix sockets are disabled. Required for online reboot (-R) to work. Note: Not supported on Windows systems.
    Default: /tmp

unix_socket_mode
    File system mode for Unix socket.
    Default: 0777

unix_socket_group
    Group name to use for Unix socket.
    Default: not set

user
    If set, specifies the Unix user to change to after startup. Works only if pgbouncer is started as root or if it's already running as given user.
    Note: Not supported on Windows systems.
    Default: not set

auth_file
    The name of the file to load user names and passwords from. See the section called “Authentication File Format” for details.
    Default: not set

auth_hba_file
    HBA configuration file to use when auth_type is hba. Supported from version 1.7 onwards.
    Default: not set

auth_type
    How to authenticate users.
Pluggable Authentication Modules (PAM) method is used to authenticate users, `auth_file` is ignored. This method is not compatible with databases using `auth_user` option. Service name reported to PAM is `pgbouncer`. Also, PAM is still not supported in HBA configuration file.

Actual authentication type is loaded from `auth_hba_file`. This allows different authentication methods different access paths. Example: connection over Unix socket uses peer authentication method, connection over TCP must use TLS. Supported from version 1.7 onwards.

Client must connect over TLS connection with valid client certificate. Username is then taken from CommonName field from certificate.

Use MD5-based password check. This is the default authentication method. `auth_file` may contain both MD5-encrypted or plain-text passwords. If `md5` is configured and a user has a SCRAM secret, then SCRAM authentication is used automatically instead.

Use password check with SCRAM-SHA-256. `auth_file` has to contain SCRAM secrets or plain-text passwords. Note that SCRAM secrets can only be used for verifying the password of a client but not for logging into a server. To be able to use SCRAM on server connections, use plain-text passwords.

Clear-text password is sent over wire. Deprecated.

No authentication is done. Username must still exist in `auth_file`.

Like the `trust` method, but the username given is ignored. Requires that all databases are configured to log in as specific user. Additionally, the console database allows any user to log in as admin.

Query to load user's password from database.

Direct access to `pg_shadow` requires admin rights. It's preferable to use non-admin user that calls SECURITY DEFINER function instead.

Note that the query is run inside target database, so if a function is used it needs to be installed into each database.

**Default:** `SELECT usename, passwd FROM pg_shadow WHERE usename=$1`

If `auth_user` is set, any user not specified in `auth_file` will be queried through the `auth_query` query from `pg_shadow` in the database using `auth_user`. `auth_user`'s password will be taken from `auth_file`.

Direct access to `pg_shadow` requires admin rights. It's preferable to use non-admin user that calls SECURITY DEFINER function instead.
Default: not set

**pool_mode**

Specifies when a server connection can be reused by other clients.

**session**

Server is released back to pool after client disconnects. Default.

**transaction**

Server is released back to pool after transaction finishes.

**statement**

Server is released back to pool after query finishes. Long transactions spanning multiple statements are disallowed in this mode.

**max_client_conn**

Maximum number of client connections allowed. When increased, the file descriptor limits should also be increased. Note that actual number of file descriptors used is more than max_client_conn.

If each user connects under its own username to server, theoretical maximum used is:

max_client_conn + (max pool_size * total databases * total users)

If a database user is specified in connect string (all users connect under same username), the theoretical maximum is:

max_client_conn + (max pool_size * total databases)

The theoretical maximum should be never reached, unless somebody deliberately crafts special load for it. Still, it means you should set the number of file descriptors to a safely high number.

Search for *ulimit* in your favorite shell man page. Note: *ulimit* does not apply in a Windows environment.

Default: 100

**default_pool_size**

How many server connections to allow per user/database pair. Can be overridden in the per-database configuration.

Default: 20

**min_pool_size**

Add more server connections to pool if below this number. Improves behavior when usual load suddenly comes back after a period of total inactivity.

Default: 0 (disabled)

**reserve_pool_size**

How many additional connections to allow to a pool. The 0 value disables this parameter.

Default: 0 (disabled)

**reserve_pool_timeout**

If a client has not been serviced in this many seconds, pgbouncer enables use of additional connections from reserve pool. The 0 value disables this parameter.

Default: 5.0
max_db_connections

Do not allow more than this many connections per-database (regardless of pool — i.e. user). It should be noted that when you hit the limit, closing a client connection to one pool will not immediately allow a server connection to be established for another pool, because the server connection for the first pool is still open. Once the server connection closes (due to idle timeout), a new server connection will immediately be opened for the waiting pool.

Default: unlimited

max_user_connections

Do not allow more than this many connections per-user (regardless of pool — i.e. user). It should be noted that when you hit the limit, closing a client connection to one pool will not immediately allow a server connection to be established for another pool, because the server connection for the first pool is still open. Once the server connection closes (due to idle timeout), a new server connection will immediately be opened for the waiting pool.

server_round_robin

By default, pgbouncer reuses server connections in LIFO (last-in, first-out) manner, so that few connections get the most load. This gives best performance if you have a single server serving a database. But if there is TCP round-robin behind a database IP, then it is better if pgbouncer also uses connections in that manner, thus achieving uniform load.

Default: 0

ignore_startup_parameters

By default, pgbouncer allows only parameters it can keep track of in startup packets — client_encoding, datestyle, timezone and standard_conforming_strings.

All other parameters will raise an error. To allow other parameters, they can be specified here, so that pgbouncer knows that they are handled by admin and it can ignore them.

Default: empty

disable_pqexec

Disable Simple Query protocol (PQexec). Unlike Extended Query protocol, Simple Query allows multiple queries in one packet, which allows some classes of SQL-injection attacks. Disabling it can improve security. Obviously this means only clients that exclusively use Extended Query protocol will stay working.

Default: 0

application_name_add_host

Add the client host address and port to the application name setting set on connection start. This helps in identifying the source of bad queries, etc. This logic applies only on start of connection, if application_name is later changed with SET, pgbouncer does not change it again.

Default: 0

conffile

Show location of current configuration file. Changing it will make pgbouncer use another configuration file for next RELOAD / SIGHUP.

Default: file from command line.

service_name

Used on win32 service registration.
Additional Supplied Programs

Default: pgbouncer

job_name

Alias for service_name.

stats_period

Sets how often the averages shown in various SHOW commands are updated and how often aggregated statistics are written to the log (but see log_stats). [seconds]

Default: 60

Log Settings

syslog

Toggles syslog on/off. On Windows systems, eventlog is used instead.

Default: 0

syslog_ident

Under what name to send logs to syslog.

Default: pgbouncer (program name)

syslog_facility

Under what facility to send logs to syslog. Possibilities: auth, authpriv, daemon, user, local0-7.

Default: daemon

log_connections

Log successful logins.

Default: 1

log_disconnections

Log disconnections with reasons.

Default: 1

log_pooler_errors

Log error messages pooler sends to clients.

Default: 1

stats_period

Period for writing aggregated stats into log.

Default: 60

log_stats

Write aggregated statistics into the log, every stats_period. This can be disabled if external monitoring tools are used to grab the same data from SHOW commands.

Default: 1

verbose

Increase verbosity. Mirrors "-v" switch on command line. Using "-v -v" on command line is same as verbose=2 in configuration file.
Additional Supplied Programs

**Console Access Control**

**admin_users**

Comma-separated list of database users that are allowed to connect and run all commands on console. Ignored when `auth_type` is any, in which case any username is allowed in as admin.

Default: empty

**stats_users**

Comma-separated list of database users that are allowed to connect and run read-only queries on console. That means all SHOW commands except SHOW FDS.

Default: empty.

**Connection Sanity Checks, Timeouts**

**server_reset_query**

Query sent to server on connection release, before making it available to other clients. At that moment no transaction is in progress so it should not include `ABORT` or `ROLLBACK`.

The query is supposed to clean any changes made to database session so that next client gets connection in well-defined state. Default is `DISCARD ALL` which cleans everything, but that leaves next client no pre-cached state. It can be made lighter, e.g. `DEALLOCATE ALL` to just drop prepared statements, if application does not break when some state is kept around.

When transaction pooling is used, the `server_reset_query` is not used, as clients must not use any session-based features as each transaction ends up in different connection and thus gets different session state.

Default: `DISCARD ALL`

**server_reset_query_always**

Whether `server_reset_query` should be run in all pooling modes. When this setting is off (default), the `server_reset_query` will be run only in pools that are in sessions-pooling mode. Connections in transaction-pooling mode should not have any need for reset query.

It is workaround for broken setups that run apps that use session features over transaction-pooled pgbouncer. It changes non-deterministic breakage to deterministic breakage — client always lose their state after each transaction.

Default: 0

**server_check_delay**

How long to keep released connections available for immediate re-use, without running sanity-check queries on it. If 0 then the query is always run.

Default: 30.0

**server_check_query**

Simple do-nothing query to check if the server connection is alive.

If an empty string, then sanity checking is disabled.

Default: `SELECT 1;`

**server_fast_close**

Disconnect a server in session pooling mode immediately or after the end of the current transaction if it is in close_needed mode (set by `RECONNECT, RELOAD` that changes connection settings, or DNS
change), rather than waiting for the session end. In statement or transaction pooling mode, this has no effect since that is the default behavior there.

If because of this setting a server connection is closed before the end of the client session, the client connection is also closed. This ensures that the client notices that the session has been interrupted.

This setting makes connection configuration changes take effect sooner if session pooling and long-running sessions are used. The downside is that client sessions are liable to be interrupted by a configuration change, so client applications will need logic to reconnect and reestablish session state. But note that no transactions will be lost, because running transactions are not interrupted, only idle sessions.

Default: 0

**server_lifetime**

The pooler will close an unused server connection that has been connected longer than this. Setting it to 0 means the connection is to be used only once, then closed. [seconds]

Default: 3600.0

**server_idle_timeout**

If a server connection has been idle more than this many seconds it will be dropped. If 0 then timeout is disabled. [seconds]

Default: 600.0

**server_connect_timeout**

If connection and login won't finish in this amount of time, the connection will be closed. [seconds]

Default: 15.0

**server_login_retry**

If login failed, because of failure from connect() or authentication that pooler waits this much before retrying to connect. [seconds]

Default: 15.0

**client_login_timeout**

If a client connects but does not manage to login in this amount of time, it will be disconnected. Mainly needed to avoid dead connections stalling SUSPEND and thus online restart. [seconds]

Default: 60.0

**autodb_idle_timeout**

If the automatically created (via "+") database pools have been unused this many seconds, they are freed. The negative aspect of that is that their statistics are also forgotten. [seconds]

Default: 3600.0

**dns_max_ttl**

How long the DNS lookups can be cached. If a DNS lookup returns several answers, pgbouncer will robin-between them in the meantime. Actual DNS TTL is ignored. [seconds]

Default: 15.0

**dns_nxdomain_ttl**

How long error and NXDOMAIN DNS lookups can be cached. [seconds]
Additional Supplied Programs

**Default: 15.0**

dns_zone_check_period

Period to check if zone serial has changed.

pgbouncer can collect DNS zones from host names (everything after first dot) and then periodically check if zone serial changes. If it notices changes, all host names under that zone are looked up again. If any host IP changes, it's connections are invalidated.

Works only with UDNS and c-ares backends (**--with-udns** or **--with-cares** to configure).

Default: 0.0 (disabled)

**TLS Settings**

client_tls_sslmode

TLS mode to use for connections from clients. TLS connections are disabled by default. When enabled, **client_tls_key_file** and **client_tls_cert_file** must be also configured to set up key and cert pgbouncer uses to accept client connections.

**disable**

Plain TCP. If client requests TLS, it's ignored. Default.

**allow**

If client requests TLS, it is used. If not, plain TCP is used. If client uses client-certificate, it is not validated.

**prefer**

Same as allow.

**require**

Client must use TLS. If not, client connection is rejected. If client uses client-certificate, it is not validated.

**verify-ca**

Client must use TLS with valid client certificate.

**verify-full**

Same as verify-ca.

client_tls_key_file

Private key for pgbouncer to accept client connections.

Default: not set.

client_tls_cert_file

Certificate for private key. Clients can validate it.

Default: not set.

client_tls_ca_file

Root certificate file to validate client certificates.

Default: unset.
client_tls_protocols

Which TLS protocol versions are allowed. Allowed values: tlsv1.0, tlsv1.1, tlsv1.2, tlsv1.3. Shortcuts: all (tlsv1.0,tlsv1.1,tlsv1.2,tlsv1.3), secure (tlsv1.2,tlsv1.3), legacy (all).

Default: all

client_tls_ciphers

Default: fast

client_tls_ecdhcurve

Elliptic Curve name to use for ECDH key exchanges.

Allowed values: none (DH is disabled), auto (256-bit ECDH), curve name.

Default: auto

client_tls_dheparams

DHE key exchange type.

Allowed values: none (DH is disabled), auto (2048-bit DH), legacy (1024-bit DH).

Default: auto

server_tls_sslmode

TLS mode to use for connections to Postgres Pro servers. TLS connections are disabled by default.

disable

Plain TCP. TLS is not even requested from server. Default.

prefer

TLS connection is always requested first from Postgres Pro, when refused connection will be established over plain TCP. Server certificate is not validated.

require

Connection must go over TLS. If server rejects it, plain TCP is not attempted. Server certificate is not validated.

verify-ca

Connection must go over TLS and server certificate must be valid according to server_tls_ca_file. Server host name is not checked against certificate.

verify-full

Connection must go over TLS and server certificate must be valid according to server_tls_ca_file. Server host name must match certificate info.

server_tls_ca_file

Root certificate file to validate Postgres Pro server certificates.

Default: unset.

server_tls_key_file

Private key for pgbouncer to authenticate against Postgres Pro server.

Default: not set.
server_tls_cert_file
Certificate for private key. Postgres Pro server can validate it.
Default: not set.

server_tls_protocols
Which TLS protocol versions are allowed. Allowed values: tlsv1.0, tlsv1.1, tlsv1.2, tlsv1.3. Shortcuts: all (tlsv1.0,tlsv1.1,tlsv1.2,tlsv1.3), secure (tlsv1.2,tlsv1.3), legacy (all).
Default: all

server_tls_ciphers
Default: fast

Dangerous Timeouts
Setting the following timeouts causes unexpected errors.

query_timeout
Queries running longer than that are canceled. This should be used only with slightly smaller server-side statement_timeout, to apply only for network problems. [seconds]
Default: 0.0 (disabled)

query_wait_timeout
Maximum time queries are allowed to spend waiting for execution. If the query is not assigned to a server during that time, the client is disconnected. This is used to prevent unresponsive servers from grabbing up connections. [seconds]
It also helps when server is down or database rejects connections for any reason. If this is disabled, clients will be queued infinitely.
Default: 120

client_idle_timeout
Client connections idling longer than this many seconds are closed. This should be larger than the client-side connection lifetime settings, and only used for network problems. [seconds]
Default: 0.0 (disabled)

idle_transaction_timeout
If client has been in "idle in transaction" state longer, it will be disconnected. [seconds]
Default: 0.0 (disabled)

Low-Level Network Settings

pkt_buf
Internal buffer size for packets. Affects size of TCP packets sent and general memory usage. Actual libpq packets can be larger than this, so, no need to set it large.
Default: 4096

max_packet_size
Maximum size for Postgres Pro packets that pgbouncer allows through. One packet is either one query or one result set row. Full result set can be larger.
Default: 2147483647
**Additional Supplied Programs**

**listen_backlog**

Backlog argument for listen(2). Determines how many new unanswered connection attempts are kept in queue. When queue is full, further new connections are dropped.

Default: 128

**sbuf_loopcnt**

How many times to process data on one connection, before proceeding. Without this limit, one connection with a big result set can stall pgbouncer for a long time. One loop processes one `pkt_buf` amount of data. 0 means no limit.

Default: 5

**suspend_timeout**

How many seconds to wait for buffer flush during SUSPEND or reboot (-R). Connection is dropped if flush does not succeed.

Default: 10

**tcp_defer_accept**

For details on this and other TCP options, please see `man 7 tcp`.

Default: 45 on Linux, otherwise 0

**tcp_socket_buffer**

Default: not set

**tcp_keepalive**

Turns on basic keepalive with OS defaults.

On Linux, the system defaults are `tcp_keepidle=7200, tcp_keepintvl=75, tcp_keepcnt=9`. They are probably similar on other operating systems.

Default: 1

**tcp_keepcnt**

Default: not set

**tcp_keepidle**

Default: not set

**tcp_keepintvl**

Default: not set

**Section [databases]**

This contains key=value pairs where key will be taken as a database name and value as a libpq connect-string style list of key=value pairs. As actual libpq is not used, not all features from libpq can be used (service=, .pgpass).

Database name can contain characters `_0-9A-Za-z` without quoting. Names that contain other chars need to be quoted with standard SQL ident quoting: double quotes where "" is taken as single quote.

"*" acts as fallback database: if the exact name does not exist, its value is taken as connect string for requested database. Such automatically created database entries are cleaned up if they stay idle longer than the time specified in `autodb_idle_timeout` parameter.
dbname
   Destination database name.
   Default: same as client-side database name.

host
   Host name or IP address to connect to. Host names are resolved at connect time, the result is cached
   per dns_max_ttl parameter. When a host name's resolution changes, existing server connections
   are automatically closed when they are released (according to the pooling mode), and new server
   connections immediately use the new resolution. If DNS returns several results, they are used in
   round-robin manner.
   Default: not set, meaning to use a Unix socket.

port
   Default: 5432

user
   If user= is set, all connections to the destination database will be done with the specified user,
   meaning that there will be only one pool for this database.
   Otherwise pgbouncer tries to log into the destination database with client username, meaning that
   there will be one pool per user.

password
   The length for password is limited to 160 characters maximum.
   If no password is specified here, the password from the auth_file or auth_query will be used.

auth_user
   Override of the global auth_user setting, if specified.

pool_size
   Set maximum size of pools for this database. If not set, the default_pool_size is used.

reserve_pool
   Set additional connections for this database. If not set, reserve_pool_size is used.

connect_query
   Query to be executed after a connection is established, but before allowing the connection to be used
   by any clients. If the query raises errors, they are logged but ignored otherwise.

pool_mode
   Set the pool mode specific to this database. If not set, the default pool_mode is used.

max_db_connections
   Configure a database-wide maximum (i.e. all pools within the database will not have more than this
   many server connections).

client_encoding
   Ask specific client_encoding from server.

datestyle
   Ask specific datestyle from server.
Additional Supplied Programs

timezone

Ask specific timezone from server.

Section [users]

This contains key=value pairs where the key will be taken as a user name and the value as a libpq
connect-string style list of key=value pairs of configuration settings specific for this user. Only a few
settings are available here.

pool_mode

Set the pool mode to be used for all connections from this user. If not set, the database or default
pool_mode is used.

max_user_connections

Configure a maximum for the user (i.e. all pools with the user will not have more than this many
server connections).

Include Directive

The pgbouncer config file can contain include directives, which specify another configuration file to read
and process. This allows for splitting the configuration file into physically separate parts. The include
directives look like this:

%include filename

If the file name is not absolute path it is taken as relative to current working directory.

Authentication File Format

pgbouncer needs its own user database. The users are loaded from a text file in following format:

"username1" "password" ...
"username2" "md5abcdef012342345" ...
"username2" "SCRAM-SHA-256$iterations:salt$storedkey:serverkey"

There should be at least two fields, surrounded by double quotes. The first field is the username and
the second is either a plain-text, a MD5-hidden password, or a SCRAM secret. pgbouncer ignores the
rest of the line.

Postgres Pro MD5-hidden password format:

"md5" + md5(password + username)

So user admin with password 1234 will have MD5-hidden password
md545f2603610af569b6155c45067268c6b.

Postgres Pro SCRAM secret format:

SCRAM-SHA-256$iterations:salt$storedkey:serverkey

The authentication file can be written by hand, but it’s also useful to generate it from some other list
of users and passwords. See ./etc/mkauth.py for a sample script to generate the authentication file
from the pg_shadow system table.

HBA File Format

It follows the format of Postgres Pro pg_hba.conf file described in Section 19.1.

- Supported record types: local, host, hostssl, hostnossl.
- Database field: Supports all, sameuser, @file, multiple names. Not supported: replication, sameuser, samegroup.
- Username field: Supports all, @file, multiple names. Not supported: +groupname.
• Auth-method field: Only methods supported by pgbouncer's auth_type are supported, except any and pam, which only work globally. Username map (map=) parameter is not supported.

Example

Minimal config:

```
[databases]
template1 = host=127.0.0.1 dbname=template1 auth_user=someuser

[pgbouncer]
pool_mode = session
listen_port = 6543
listen_addr = 127.0.0.1
auth_type = md5
auth_file = users.txt
logfile = pgbouncer.log
pidfile = pgbouncer.pid
admin_users = someuser
stats_users = stat_collector
```

Database defaults:

```
[databases]

; foodb over Unix socket
foodb =

; redirect bardb to bazdb on localhost
bardb = host=127.0.0.1 dbname=bazdb

; access to destination database will go with single user
forcedb = host=127.0.0.1 port=300 user=baz password=foo client_encoding=UNICODE datestyle=ISO
```

Example of a secure function for auth_query:

```
CREATE OR REPLACE FUNCTION pgbouncer.user_lookup(in i_username text, out uname text, out phash text)
RETURNS record AS $$
BEGIN
SELECT usename, passwd FROM pg_catalog.pg_shadow
WHERE usename = i_username INTO uname, phash;
RETURN;
END;
$$ LANGUAGE plpgsql SECURITY DEFINER;
REVOKE ALL ON FUNCTION pgbouncer.user_lookup(text) FROM public, pgbouncer;
GRANT EXECUTE ON FUNCTION pgbouncer.user_lookup(text) TO pgbouncer;
```
pgpro_controldata

pgpro_controldata — display control information of a PostgreSQL/Postgres Pro database cluster and compatibility information for a cluster and/or server

Synopsis

pgpro_controldata [option...]

Description

pgpro_controldata prints control information, such as the catalog version, initialized by initdb command of any PostgreSQL/Postgres Pro server. It also shows information about write-ahead logging and checkpoint processing. This information is cluster-wide and not specific to any database.

pgpro_controldata also helps to check compatibility between PostgreSQL/Postgres Pro database servers and clusters. It can print server or cluster parameters that can affect the compatibility and check whether a cluster and server are compatible by comparing those parameters.

Options

pgpro_controldata accepts the following command-line arguments. If no arguments are specified, pgpro_controldata just prints the control information like pg_controldata does. Note that compatibility-related command-line arguments -P and -S specified together work the same way as -C.

General-Purpose

-B
--bindir
   Specifies the PostgreSQL/Postgres Pro executable directory, needed to get server compatibility parameters.

-D datadir
--pgdata=datadir
   Specifies the file system location of the database configuration files. If this option is omitted, the environment variable PGDATA is used.

-V
--version
   Print the pgpro_controldata version, then exit.

-?
--help
   Show help about pgpro_controldata command-line arguments, then exit.

Compatibility-Related

-C
--compatibility-check
   Display all parameters that can affect compatibility between the specified server and cluster and check whether they are compatible.

   Use the -D option or the environment variable PGDATA to provide the path to the data directory, where read access is required.

   If the -B option is omitted, the current server is assumed.
The cluster data and the server must have the same byte order and architecture type for this option to work correctly.

-P
--cluster-compatibility-params
Display all parameters of the specified cluster that can affect the compatibility.

Use the -D option or the environment variable PGDATA to provide the path to the data directory, where read access is required.

The cluster data and the server must have the same byte order and architecture type for this option to work correctly.

-S
--server-compatibility-params
Display all parameters of the specified or current server that can affect the compatibility.

If the -B option is omitted, the current server is assumed.

Environment

PGDATA
Default data directory location

PG_COLOR
Specifies whether to use color in diagnostic messages. Possible values are always, auto and never.

See Also

pg_controldata
pg_integrity_check

pg_integrity_check — calculate and validate checksums for controlled files (certified edition only)

Synopsis

Description

`pg_integrity_check` is a utility provided with Postgres Pro Standard that can calculate and validate checksums for the objects you would like to control. When running `pg_integrity_check`, you must specify at least one of the options that define the type of the controlled objects: `--system`, `--user`, or `--catalog` for read-only files, additional files, or system catalog tables, respectively.

If you use the `--output` option, `pg_integrity_check` calculates checksums and writes them into configuration files under the `share/security/` directory. You must have write access to the corresponding files to perform this command. You cannot use the `--output` option together with the `--system` option, since a checksum for read-only files cannot be overwritten.

If you omit the `--output` option, `pg_integrity_check` compares the calculated checksums with the corresponding checksums in the configuration files. If the checksums differ for any of the controlled objects, `pg_integrity_check` displays a message indicating the difference.

For details on using `pg_integrity_check`, see Section 31.2.

Options

connection-options

Standard options for connecting to a database: `-d`, `-h`, `-p`, `-U`. You must specify `-d` and `-U` options when validating checksums for catalog tables with the `--catalog` option. For detailed description of connection options, see `psql`.

-s

`--system`

Validate checksums for read-only files. Checksums for read-only files control both file contents and file attributes.

-u

`--user`

Validate checksums for additional files. Checksums for additional files control both file contents and file attributes.

-c

`--catalog`

Validate checksums for system catalog tables. For the `--catalog` option to work correctly, you must also specify connection parameters for the database. The database server must be started and accept connections.

-o

`--output`

Recalculate checksums and write it into a file.

-D datadir

Data directory of the database cluster. This option is required to define the filenames for the generated configuration files when using `--user` option.
-v
--verbose
Print debugging information.

-?
--help
Print command-line help.

Return Values
0 — checksums are calculated or validated successfully.
1 — an error occurred during the initial checksum calculation for read-only files.
2 — checksum validation revealed changes in one or more of the controlled objects.
3 — an unexpected error occurred during checksum validation.

Examples
Compute checksums for additional files and write them into the share/security/_var_lib_pgpro_std-14_data.user.conf configuration file:

```
pg_integrity_check -u -o -D /var/lib/pgpro/std-14/data
```

Check integrity of all controlled objects in the postgres database on behalf of the postgres user:

```
pg_integrity_check -s -u -c -D /var/lib/pgpro/std-14/data -d postgres -h localhost -p 5432 -U postgres
```
Appendix H. External Projects

Postgres Pro is a complex software project, and managing the project is difficult. We have found that many enhancements to Postgres Pro can be more efficiently developed separately from the core project.

H.1. Client Interfaces

There are only two client interfaces included in the base Postgres Pro Standard distribution:

- **libpq** is included because it is the primary C language interface, and because many other client interfaces are built on top of it.
- **ECPG** is included because it depends on the server-side SQL grammar, and is therefore sensitive to changes in Postgres Pro itself.

All other language interfaces are external projects and are distributed separately. Table H.1 includes a list of some of these projects. Note that some of these packages might not be released under the same license as Postgres Pro. For more information on each language interface, including licensing terms, refer to its website and documentation.

H.2. Administration Tools

There are several administration tools available for Postgres Pro. The most popular is **pgAdmin**, and there are several commercially available ones as well.

H.3. Procedural Languages

Postgres Pro includes several procedural languages with the base distribution: **PL/pgSQL**, **PL/Tcl**, **PL/Perl**, and **PL/Python**.

In addition, there are a number of procedural languages that are developed and maintained outside the core Postgres Pro distribution. Table H.2 lists some of these packages. Note that some of these projects might not be released under the same license as Postgres Pro. For more information on each procedural language, including licensing information, refer to its website and documentation.
## External Projects

</tr>
</tbody>
</table>

### H.4. Extensions

Postgres Pro is designed to be easily extensible. For this reason, extensions loaded into the database can function just like features that are built in. The `contrib/` directory shipped with the source code contains several extensions, which are described in Appendix F. Other extensions are developed independently, like PostGIS. Even Postgres Pro replication solutions can be developed externally. For example, Slony-I is a popular primary/standby replication solution that is developed independently from the core project.
Appendix I. Configuring Postgres Pro for 1C Solutions

You can install and use Postgres Pro with 1C solutions in a client/server model. For optimal performance and stability, modify the following settings in the `postgresql.conf` configuration file of Postgres Pro server:

1. Increase the maximum number of allowed concurrent connections to the database server, up to 1000 connections. 1C solutions can open a large number of connections, even if not all of them are used, so it is recommended to allow not less than 500 connections.

   ```
   max_connections = 1000
   ```

2. To ensure that temporary tables are handled correctly, modify the following parameters:
   - Increase the buffer size for temporary tables:
     ```
     temp_buffers = 32MB
     ```
   - Increase the number of allowed locks of tables or indexes per transaction to 256:
     ```
     max_locks_per_transaction = 256
     ```

3. Enable backslash escapes in all strings, and switch off the warning about using the backslash escape symbol:
   ```
   standard_conforming_strings = off
   escape_string_warning = off
   ```

4. Set the `effective_cache_size` parameter to at least half of RAM available on the system. Postgres Pro query optimizer performance depends on the amount of allocated RAM.

5. Optimize query planning using `online_analyze` and `plantuner` extensions, as follows:
   - Add `online_analyze` and `plantuner` to the `shared_preload_libraries` variable.
     ```
     shared_preload_libraries = 'online_analyze, plantuner'
     ```
   - Enable automatic analysis of temporary tables when they are modified:
     ```
     online_analyze.table_type = 'temporary'
     ```
   - Tune Postgres Pro optimizer to improve planning for recently created empty tables:
     ```
     plantuner.fix_empty_table = 'on'
     ```
   - Suppress detailed messages from the `online_analyze` extension:
     ```
     online_analyze.verbose = 'off'
     ```
Appendix J. Postgres Pro Limits

Table J.1 describes various hard limits of Postgres Pro. However, practical limits, such as performance limitations or available disk space may apply before absolute hard limits are reached.

Table J.1. Postgres Pro Limitations

<table>
<thead>
<tr>
<th>Item</th>
<th>Upper Limit</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>database size</td>
<td>unlimited</td>
<td></td>
</tr>
<tr>
<td>number of databases</td>
<td>4,294,950,911</td>
<td></td>
</tr>
<tr>
<td>relations per database</td>
<td>1,431,650,303</td>
<td></td>
</tr>
<tr>
<td>relation size</td>
<td>32 TB</td>
<td>with the default BLCKSZ of 8192 bytes</td>
</tr>
<tr>
<td>rows per table</td>
<td>limited by the number of tuples that can fit onto 4,294,967,295 pages</td>
<td>further limited by tuple size fitting on a single page; see note below</td>
</tr>
<tr>
<td>columns per table</td>
<td>1600</td>
<td></td>
</tr>
<tr>
<td>field size</td>
<td>1 GB</td>
<td></td>
</tr>
<tr>
<td>identifier length</td>
<td>63 bytes</td>
<td>can be increased by recompiling Postgres Pro</td>
</tr>
<tr>
<td>indexes per table</td>
<td>unlimited</td>
<td>constrained by maximum relations per database</td>
</tr>
<tr>
<td>columns per index</td>
<td>32</td>
<td>can be increased by recompiling Postgres Pro</td>
</tr>
<tr>
<td>partition keys</td>
<td>32</td>
<td>can be increased by recompiling Postgres Pro</td>
</tr>
</tbody>
</table>

The maximum number of columns for a table is further reduced as the tuple being stored must fit in a single 8192-byte heap page. For example, excluding the tuple header, a tuple made up of 1600 int columns would consume 6400 bytes and could be stored in a heap page, but a tuple of 1600 bigint columns would consume 12800 bytes and would therefore not fit inside a heap page. Variable-length fields of types such as text, varchar, and char can have their values stored out of line in the table's TOAST table when the values are large enough to require it. Only an 18-byte pointer must remain inside the tuple in the table's heap. For shorter length variable-length fields, either a 4-byte or 1-byte field header is used and the value is stored inside the heap tuple.

Columns that have been dropped from the table also contribute to the maximum column limit. Moreover, although the dropped column values for newly created tuples are internally marked as null in the tuple's null bitmap, the null bitmap also occupies space.
Appendix K. Demo Database
“Airlines”

This is an overview of a demo database for Postgres Pro. This appendix describes the database schema, which consists of eight tables and several views. The subject field of this database is airline flights in Russia. You can download the database from our website. See Section K.1 for details.

Figure K.1. Airlines in Russia

You can use this database for various purposes, such as:
• learning SQL language on your own
• preparing books, manuals, and courses on SQL
• showing Postgres Pro features in stories and articles

When developing this demo database, we pursued several goals:
• Database schema must be simple enough to be understood without extra explanations.
• At the same time, database schema must be complex enough to allow writing meaningful queries.
• The database must contain true-to-life data that will be interesting to work with.

This demo database is distributed under the PostgreSQL license.

You can send us your feedback to edu@postgrespro.ru.

K.1. Installation

The demo database is available at edu.postgrespro.com in three flavors, which differ only in the data size:
• demo-small-en.zip (21 MB) — flight data for one month (DB size is about 300 MB)
• demo-medium-en.zip (62 MB) — flight data for three months (DB size is about 700 MB)
• demo-big-en.zip (232 MB) — flight data for one year (DB size is about 2.5 GB)

The small database is good for writing queries, and it will not take up much disk space. The large database can help you understand the query behavior on large data volumes and consider query optimization.
The files include an SQL script that creates the demo database and fills it with data (virtually, it is a backup copy created with the pg_dump utility). Note that if the demo database already exists, it will be deleted and recreated! The owner of the demo database will be the DBMS user who runs the script.

**K.2. Schema Diagram**

Figure K.2. Bookings Schema Diagram

**K.3. Schema Description**

The main entity is a booking (bookings).

One booking can include several passengers, with a separate ticket (tickets) issued to each passenger. A ticket has a unique number and includes information about the passenger. As such, the passenger is not a separate entity. Both the passenger’s name and identity document number can change over time, so it is impossible to uniquely identify all the tickets of a particular person; for simplicity, we can assume that all passengers are unique.

The ticket includes one or more flight segments (ticket_flights). Several flight segments can be included into a single ticket if there are no non-stop flights between the points of departure and destination (connecting flights), or if it is a round-trip ticket. Although there is no constraint in the schema, it is assumed that all tickets in the booking have the same flight segments.

Each flight (flights) goes from one airport (airports) to another. Flights with the same flight number have the same points of departure and destination, but differ in departure date.

At flight check-in, the passenger is issued a boarding pass (boarding_passes), where the seat number is specified. The passenger can check in for the flight only if this flight is included into the ticket. The flight-seat combination must be unique to avoid issuing two boarding passes for the same seat.

The number of seats (seats) in the aircraft and their distribution between different travel classes depends on the model of the aircraft (aircrafts) performing the flight. It is assumed that every aircraft model has only one cabin configuration. Database schema does not check that seat numbers in boarding
passes have the corresponding seats in the aircraft (such verification can be done using table triggers, or at the application level).

Check constraints:

- CHECK (range > 0)

Referenced by:
K.4.4. View bookings.airports

An airport is identified by a three-letter code (airport_code) and has a name (airport_name).

There is no separate entity for the city, but there is a city name (city) to identify the airports of the same city. The view also includes coordinates (coordinates) and the time zone (timezone).

The values of the airport_name and city fields are selected according to the chosen language. See Section K.4.15 for details.

<table>
<thead>

TABLE "flights" FOREIGN KEY (departure_airport)
    REFERENCES airports_data(airport_code)
```

K.4.6. Table bookings.boarding_passes

At the time of check-in, which opens twenty-four hours before the scheduled departure, the passenger is issued a boarding pass. Like the flight segment, the boarding pass is identified by the ticket number and the flight number.
Boarding passes are assigned sequential numbers (boarding_no), in the order of check-ins for the flight (this number is unique only within the context of a particular flight). The boarding pass specifies the seat number (seat_no).

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>

- UNIQUE CONSTRAINT, btree (flight_id, seat_no)

Foreign-key constraints:
- FOREIGN KEY (ticket_no, flight_id)
  REFERENCES ticket_flights(ticket_no, flight_id)

K.4.7. Table bookings.bookings

Passengers book tickets for themselves, and, possibly, for several other passengers, in advance (book_date, not earlier than one month before the flight). The booking is identified by its number (book_ref, a six-position combination of letters and digits).

The total_amount field stores the total cost of all tickets included into the booking, for all passengers.

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Modifiers</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

<td>Total booking cost</td>
</tr>
</tbody>
</table>

Indexes:
- PRIMARY KEY, btree (book_ref)

Referenced by:
- TABLE "tickets" FOREIGN KEY (book_ref) REFERENCES bookings(book_ref)

K.4.8. Table bookings.flights

The natural key of the bookings.flights table consists of two fields — flight_no and scheduled_departure. To make foreign keys for this table more compact, a surrogate key is used as the primary key (flight_id).

A flight always connects two points — the airport of departure (departure_airport) and arrival (arrival_airport). There is no such entity as a “connecting flight”: if there are no non-stop flights from one airport to another, the ticket simply includes several required flight segments.

Each flight has a scheduled date and time of departure (scheduled_departure) and arrival (scheduled_arrival). The actual departure time (actual_departure) and arrival time (actual_arrival) can differ: the difference is usually not very big, but sometimes can be up to several hours if the flight is delayed.

Flight status (status) can take one of the following values:

Scheduled

The flight is available for booking. It happens one month before the planned departure date; before that time, there is no entry for this flight in the database.
On Time

The flight is open for check-in (in twenty-four hours before the scheduled departure) and is not delayed.

Delayed

The flight is open for check-in (in twenty-four hours before the scheduled departure) but is delayed.

Departed

The aircraft has already departed and is airborne.

Arrived

The aircraft has reached the point of destination.

Cancelled

The flight is canceled.

<table>

Referenced by:
    TABLE "boarding_passes" FOREIGN KEY (ticket_no, flight_id)
        REFERENCES ticket_flights(ticket_no, flight_id)

K.4.11. Table bookings.tickets

A ticket has a unique number (ticket_no) that consists of 13 digits.

The ticket includes a passenger ID (passenger_id) — the identity document number, — their first and last names (passenger_name), and contact information (contact_data).

Neither the passenger ID, nor the name is permanent (for example, one can change the last name or passport), so it is impossible to uniquely identify all tickets of a particular passenger.

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>

Foreign-key constraints:
    FOREIGN KEY (book_ref)
        REFERENCES bookings(book_ref)

Referenced by:
K.4.12. View bookings.flights_v

There is a flights_v view over the flights table that provides additional information:

- Details about the airport of departure — departure_airport, departure_airport_name, departure_city
- Details about the airport of arrival — arrival_airport, arrival_airport_name, arrival_city
- Local departure time — scheduled_departure_local, actual_departure_local
- Local arrival time — scheduled_arrival_local, actual_arrival_local
- Flight duration — scheduled_duration, actual_duration.

K.4.13. View bookings.routes

The bookings.flights table contains some redundancies, which you can use to single out route information (flight number, airports of departure and destination) that does not depend on the exact flight dates.

Such information is shown in the routes view.

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</tbody>
</table>
K.4.14. Function bookings.now

The demo database contains “snapshots” of data — similar to a backup copy of a real system captured at some point in time. For example, if a flight has the Departed status, it means that the aircraft had already departed and was airborne at the time of the backup copy.

The “snapshot” time is saved in the bookings.now() function. You can use this function in demo queries for cases where you would use the now() function in a real database.

In addition, the return value of this function determines the version of the demo database. The latest version available is of August 15, 2017.

K.4.15. Function bookings.lang

Some fields in the demo database are available in English and Russian. Translations to other languages are not provided, but are easy to add. The bookings.lang returns the value of the bookings.lang parameter, that is, the language in which these fields will be displayed.

This function is used in the aircrafts and airports views and is not intended to be used directly in queries.

K.5. Usage

K.5.1. Schema bookings

The bookings schema contains all objects of the demo database. When you connect to the database, search_path configuration parameter is automatically set to bookings, public, so you do not need to specify the schema name explicitly.

However, for the bookings.now function, you always have to specify the schema to distinguish this function from the standard now function.

K.5.2. Translations

By default, values of several translatable fields are shown in Russian. These are airport_name and city of the airports view, as well as model of the aircrafts view.

You can choose to display these fields in another language (although only the English translation is provided in the demo database). To switch to English, set the bookings.lang parameter to en. It may be convenient to choose the language at the database level:

```
ALTER DATABASE demo SET bookings.lang = en;
```

You have to reconnect to the database for this command to take effect. For other methods of settings configuration parameters, see Section 18.1.

In the examples below, the English language is selected for translatable fields.

K.5.3. Sample Queries

To better understand the contents of the demo database, let’s take a look at the results of several simple queries.
All flights are operated by several types of aircraft:

```
SELECT * FROM aircrafts;
```

| aircraft_code | model                  | range |
|---------------|------------------------+-------|
| 773           | Boeing 777-300         | 11100 |
| 763           | Boeing 767-300         | 7900  |
| SU9           | Sukhoi SuperJet-100    | 3000  |
| 320           | Airbus A320-200        | 5700  |
| 321           | Airbus A321-200        | 5600  |
| 319           | Airbus A319-100        | 6700  |
| 733           | Boeing 737-300         | 4200  |
| CN1           | Cessna 208 Caravan     | 1200  |
| CR2           | Bombardier CRJ-200     | 2700  |

(9 rows)

For each aircraft type, a separate list of seats is supported. For example, in a small Cessna 208 Caravan, one can select the following seats:

```
SELECT   a.aircraft_code, 
         a.model, 
         s.seat_no, 
         s.fare_conditions
FROM     aircrafts a 
JOIN seats s ON a.aircraft_code = s.aircraft_code 
WHERE    a.model = 'Cessna 208 Caravan' 
ORDER BY s.seat_no;
```

| aircraft_code | model                  | seat_no | fare_conditions |
|---------------|------------------------+---------|-----------------|
| CN1           | Cessna 208 Caravan     | 1A      | Economy        |
| CN1           | Cessna 208 Caravan     | 1B      | Economy        |
| CN1           | Cessna 208 Caravan     | 2A      | Economy        |
| CN1           | Cessna 208 Caravan     | 2B      | Economy        |
| CN1           | Cessna 208 Caravan     | 3A      | Economy        |
| CN1           | Cessna 208 Caravan     | 3B      | Economy        |
| CN1           | Cessna 208 Caravan     | 4A      | Economy        |
| CN1           | Cessna 208 Caravan     | 4B      | Economy        |
| CN1           | Cessna 208 Caravan     | 5A      | Economy        |
| CN1           | Cessna 208 Caravan     | 5B      | Economy        |
| CN1           | Cessna 208 Caravan     | 6A      | Economy        |
| CN1           | Cessna 208 Caravan     | 6B      | Economy        |

(12 rows)

Bigger aircraft have more seats of various travel classes:

```
SELECT s2.aircraft_code, 
       string_agg (s2.fare_conditions || ' (' || s2.num::text || ' )', 
                    ',', '') as fare_conditions 
FROM   ( 
        SELECT s.aircraft_code, s.fare_conditions, count(*) as num
FROM seats s
GROUP BY s.aircraft_code, s.fare_conditions
ORDER BY s.aircraft_code, s.fare_conditions
) s2
GROUP BY s2.aircraft_code
ORDER BY s2.aircraft_code;

<table>
<thead>
<tr>
<th>aircraft_code</th>

</tbody>
</table>

(9 rows)

The demo database contains the list of airports of almost all major Russian cities. Most cities have only one airport. The exceptions are:

```sql
SELECT a.airport_code as code,
       a.airport_name,
       a.city,
       a.coordinates
FROM airports a
WHERE a.city IN (
    SELECT aa.city
    FROM airports aa
    GROUP BY aa.city
    HAVING COUNT(*) > 1
)
ORDER BY a.city, a.airport_code;
```

<table>
<thead>

(5 rows)

To learn about your flying options from one point to another, it is convenient to use the routes materialized view that aggregates information on all flights. For example, here are the destinations where you can get from Volgograd on specific days of the week, with flight duration:

```sql
SELECT r.arrival_city as city,
       r.arrival_airport as code,
       r.arrival_airport_name as airport_name,
FROM routes r
WHERE r.departure_city = 'Volgograd'
ORDER BY r.arrival_city, r.arrival_airport;
select r.days_of_week, r.duration
from routes r
where r.departure_city = 'Volgograd';

<table>
<thead>
<tr>
<th>city</th>
<th>code</th>
<th>airport_name</th>
<th>days_of_week</th>
<th>duration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Moscow</td>
<td>SVO</td>
<td>Sheremetyevo International Airport</td>
<td>{1,2,3,4,5,6,7}</td>
<td>01:15:00</td>
</tr>
<tr>
<td>Chelyabinsk</td>
<td>CEK</td>
<td>Chelyabinsk Balandino Airport</td>
<td>{1,2,3,4,5,6,7}</td>
<td>01:50:00</td>

</tr>
<tr>
<td>Tomsk</td>
<td>TOF</td>
<td>Bogashevo Airport</td>
<td>{1}</td>
<td>03:50:00</td>
</tr>
</tbody>
</table>
(6 rows)

The database was formed at the moment returned by the `bookings.now()` function:

```sql
SELECT bookings.now() as now;
```

```
now
------------------------
2017-08-15 18:00:00+03
```

In relation to this moment, all flights are classified as past and future flights:

```sql
SELECT status, count(*) as count, min(scheduled_departure) as min_scheduled_departure, max(scheduled_departure) as max_scheduled_departure
FROM flights
GROUP BY status
ORDER BY min_scheduled_departure;
```

```
<table>
<thead>
<tr>
<th>status</th>
<th>count</th>
<th>min_scheduled_departure</th>
<th>max_scheduled_departure</th>
</tr>
</thead>
<tbody>
<tr>
<td>Arrived</td>
<td>16707</td>
<td>2017-07-16 01:50:00+03</td>

</tr>
</tbody>
</table>
(6 rows)

Let's find the next flight from Yekaterinburg to Moscow. The `flight` table is not very convenient for such queries, as it does not include information on the cities of departure and arrival. That is why we will use the `flights_v` view:

```sql
\x
SELECT f.*
FROM flights_v f
WHERE f.departure_city = 'Yekaterinburg'
AND f.arrival_city = 'Moscow'
AND f.scheduled_departure > bookings.now()
ORDER BY f.scheduled_departure
LIMIT 1;
```

2632
Demo Database “Airlines”

- [ RECORD 1 ]----------------------------------------------------------
  flight_id | 10927
  flight_no | PG0226
  scheduled_departure | 2017-08-16 08:10:00+03
  scheduled_departure_local | 2017-08-16 10:10:00
  scheduled_arrival | 2017-08-16 09:55:00+03
  scheduled_arrival_local | 2017-08-16 09:55:00
  scheduled_duration | 01:45:00
  departure_airport | SVX
  departure_airport_name | Koltsovo Airport
  departure_city | Yekaterinburg
  arrival_airport | SVO
  arrival_airport_name | Sheremetyevo International Airport

  status | On Time
  aircraft_code | 773
  actual_departure |
  actual_departure_local |
  actual_arrival |
  actual_arrival_local |
  actual_duration |

Note that the flights_v view shows both Moscow time and local time at the airports of departure and arrival.

K.5.4. Bookings

Each booking can include several tickets, one for each passenger. The ticket, in its turn, can include several flight segments. The complete information about the booking is stored in three tables: bookings, tickets, and ticket_flights.

Let’s find several most expensive bookings:

```
SELECT *
FROM bookings
ORDER BY total_amount desc
LIMIT 10;
```

<table>
<thead>
<tr>
<th>book_ref</th>
<th>book_date</th>
<th>total_amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>3B54BB</td>
<td>2017-07-05 17:08:00+03</td>
<td>1204500.00</td>
</tr>
<tr>
<td>3AC131</td>
<td>2017-07-31 01:06:00+03</td>
<td>1087100.00</td>
</tr>
<tr>
<td>65A6EA</td>
<td>2017-07-03 06:28:00+03</td>
<td>1065600.00</td>
</tr>
<tr>
<td>D7E9AA</td>
<td>2017-08-08 05:29:00+03</td>
<td>1062800.00</td>
</tr>
<tr>
<td>EF479E</td>
<td>2017-08-02 15:58:00+03</td>
<td>1035100.00</td>
</tr>
<tr>
<td>521C53</td>
<td>2017-07-08 09:25:00+03</td>
<td>985500.00</td>
</tr>
<tr>
<td>514CA6</td>
<td>2017-07-27 05:07:00+03</td>
<td>955000.00</td>
</tr>
<tr>
<td>D70BD9</td>
<td>2017-07-05 12:47:00+03</td>
<td>947500.00</td>
</tr>
<tr>
<td>EC7EDA</td>
<td>2017-07-02 16:13:00+03</td>
<td>946800.00</td>
</tr>
<tr>
<td>8E4370</td>
<td>2017-07-28 02:04:00+03</td>
<td>945700.00</td>
</tr>
</tbody>
</table>

(10 rows)

Let’s take a look at the tickets included into the booking with code 521C53:

```
SELECT ticket_no,
       passenger_id,
       passenger_name
FROM tickets
```
WHERE book_ref = '521C53';

<table>
<thead>
<tr>
<th>ticket_no</th>
<th>passenger_id</th>
<th>passenger_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>0005432661914</td>
<td>8234 547529</td>
<td>IVAN IVANOV</td>
</tr>
<tr>
<td>0005432661915</td>
<td>2034 201228</td>
<td>ANTONINA KUZNECOVA</td>
</tr>
</tbody>
</table>

(2 rows)

If we would like to know, which flight segments are included into Antonina Kuznecova's ticket, we can use the following query:

```sql
SELECT to_char(f.scheduled_departure, 'DD.MM.YYYY') AS when,
       f.departure_city || ' (' || f.departure_airport || ')' AS departure,
       f.arrival_city || ' (' || f.arrival_airport || ')' AS arrival,
       tf.fare_conditions AS class,
       tf.amount
FROM ticket_flights tf
     JOIN flights_v f ON tf.flight_id = f.flight_id
WHERE tf.ticket_no = '0005432661915'
ORDER BY f.scheduled_departure;
```

<table>
<thead>
<tr>
<th>when</th>
<th>departure</th>
<th>arrival</th>
<th>class</th>
<th>amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>29.07.2017</td>
<td>Moscow (SVO)</td>
<td>Anadyr (DYR)</td>
<td>Business</td>
<td>185300.00</td>
</tr>
<tr>
<td>02.08.2017</td>
<td>Anadyr (DYR)</td>
<td>Khabarovsk (KHV)</td>
<td>Business</td>
<td>92200.00</td>
</tr>
<tr>
<td>03.08.2017</td>
<td>Khabarovsk (KHV)</td>
<td>Blagoveschensk (BQS)</td>
<td>Business</td>
<td>18000.00</td>
</tr>
<tr>
<td>08.08.2017</td>
<td>Blagoveschensk (BQS)</td>
<td>Khabarovsk (KHV)</td>
<td>Business</td>
<td>18000.00</td>
</tr>
<tr>
<td>12.08.2017</td>
<td>Khabarovsk (KHV)</td>
<td>Anadyr (DYR)</td>
<td>Economy</td>
<td>30700.00</td>
</tr>
<tr>
<td>17.08.2017</td>
<td>Anadyr (DYR)</td>
<td>Moscow (SVO)</td>
<td>Business</td>
<td>185300.00</td>
</tr>
</tbody>
</table>

(6 rows)

As we can see, high booking cost is explained by multiple long-haul flights in business class.

Some of the flight segments in this ticket have earlier dates than the `bookings.now()` return value: it means that these flights had already happened. The last flight had not happened yet at the time of the database creation. After the check-in, a boarding pass with the allocated seat number is issued. We can check the exact seats occupied by Antonina (note the outer left join with table `boarding_passes`):

```sql
SELECT to_char(f.scheduled_departure, 'DD.MM.YYYY') AS when,
       f.departure_city || ' (' || f.departure_airport || ')' AS departure,
       f.arrival_city || ' (' || f.arrival_airport || ')' AS arrival,
       f.status,
       bp.seat_no
FROM ticket_flights tf
     JOIN flights_v f ON tf.flight_id = f.flight_id
     LEFT JOIN boarding_passes bp ON tf.flight_id = bp.flight_id
     AND tf.ticket_no = bp.ticket_no
WHERE tf.ticket_no = '0005432661915'
ORDER BY f.scheduled_departure;
```

<table>
<thead>
<tr>
<th>when</th>
<th>departure</th>
<th>arrival</th>
<th>status</th>
<th>seat_no</th>
</tr>
</thead>
<tbody>
<tr>
<td>29.07.2017</td>
<td>Moscow (SVO)</td>
<td>Anadyr (DYR)</td>
<td>Arrived</td>
<td>5C</td>
</tr>
<tr>
<td>02.08.2017</td>
<td>Anadyr (DYR)</td>
<td>Khabarovsk (KHV)</td>
<td>Arrived</td>
<td>1D</td>
</tr>
<tr>
<td>03.08.2017</td>
<td>Khabarovsk (KHV)</td>
<td>Blagoveschensk (BQS)</td>
<td>Arrived</td>
<td>2C</td>
</tr>
<tr>
<td>08.08.2017</td>
<td>Blagoveschensk (BQS)</td>
<td>Khabarovsk (KHV)</td>
<td>Arrived</td>
<td>2D</td>
</tr>
</tbody>
</table>

(6 rows)
K.5.5. New Booking

Let's try to send Aleksandr Radishchev from Saint Petersburg to Moscow — the route that made him famous. Naturally, he will travel for free and in business class. We have already found a flight for tomorrow, and a return flight a week later.

BEGIN;

INSERT INTO bookings (book_ref, book_date, total_amount)
VALUES      ('_QWE12', bookings.now(), 0);

INSERT INTO tickets (ticket_no, book_ref, passenger_id, passenger_name)
VALUES      ('_000000000001', '_QWE12', '1749 051790', 'ALEKSANDR RADISHCHEV');

INSERT INTO ticket_flights (ticket_no, flight_id, fare_conditions, amount)
VALUES      ('_000000000001', 8525, 'Business', 0),
            ('_000000000001', 4967, 'Business', 0);

COMMIT;

To avoid conflicts with the range of values present in the database, identifiers are started with an underscore.

We will check in Aleksandr for tomorrow's flight right away:

INSERT INTO boarding_passes (ticket_no, flight_id, boarding_no, seat_no)
VALUES      ('_000000000001', 8525, 1, '1A');

Now let's check the booking information:

SELECT   b.book_ref,
         t.ticket_no,
         t.passenger_id,
         t.passenger_name,
         tf.fare_conditions,
         tf.amount,
         f.scheduled_departure_local,
         f.scheduled_arrival_local,
         f.departure_city || ' (' || f.departure_airport || ')' AS departure,
         f.arrival_city || ' (' || f.arrival_airport || ')' AS arrival,
         f.status,
         bp.seat_no
FROM     bookings b
JOIN tickets t ON b.book_ref = t.book_ref
JOIN ticket_flights tf ON tf.ticket_no = t.ticket_no
JOIN flights_v f ON tf.flight_id = f.flight_id
LEFT JOIN boarding_passes bp ON tf.flight_id = bp.flight_id

Appendix L. Acronyms

This is a list of acronyms commonly used in the Postgres Pro documentation and in discussions about Postgres Pro.

ANSI
   *American National Standards Institute*

API
   *Application Programming Interface*

ASCII
   *American Standard Code for Information Interchange*

BKI
   Backend Interface

CA
   *Certificate Authority*

CIDR
   *Classless Inter-Domain Routing*

CPAN
   *Comprehensive Perl Archive Network*

CRL
   *Certificate Revocation List*

CSV
   *Comma Separated Values*

CTE
   *Common Table Expression*

CVE
   *Common Vulnerabilities and Exposures*

DBA
   *Database Administrator*

DBI
   *Database Interface (Perl)*

DBMS
   *Database Management System*

DDL
   *Data Definition Language*, SQL commands such as `CREATE TABLE`, `ALTER USER`

DML
   *Data Manipulation Language*, SQL commands such as `INSERT`, `UPDATE`, `DELETE`
Acronyms

DST
  *Daylight Saving Time*

ECPG
  Embedded C for Postgres Pro

ESQL
  *Embedded SQL*

FAQ
  *Frequently Asked Questions*

FSM
  Free Space Map

GEQO
  Genetic Query Optimizer

GIN
  Generalized Inverted Index

GiST
  Generalized Search Tree

Git
  *Git*

GMT
  *Greenwich Mean Time*

GSSAPI
  *Generic Security Services Application Programming Interface*

GUC
  Grand Unified Configuration, the Postgres Pro subsystem that handles server configuration

HBA
  Host-Based Authentication

HOT
  *Heap-Only Tuples*

IEC
  *International Electrotechnical Commission*

IEEE
  Institute of Electrical and Electronics Engineers

IPC
  *Inter-Process Communication*

ISO
  *International Organization for Standardization*
Acronyms

ISSN
   *International Standard Serial Number*

JDBC
   *Java Database Connectivity*

JIT
   *Just-in-Time compilation*

JSON
   *JavaScript Object Notation*

LDAP
   *Lightweight Directory Access Protocol*

LSN
   Log Sequence Number, see *pg_lsn* and *WAL Internals*.

MITM
   *Man-in-the-middle attack*

MSVC
   *Microsoft Visual C*

MVCC
   *Multi-Version Concurrency Control*

NLS
   *National Language Support*

ODBC
   *Open Database Connectivity*

OID
   *Object Identifier*

OLAP
   *Online Analytical Processing*

OLTP
   *Online Transaction Processing*

ORDBMS
   *Object-Relational Database Management System*

PAM
   *Pluggable Authentication Modules*

PGSQL
   Postgres Pro

PGXS
   Postgres Pro Extension System
Acronyms

PID
  Process Identifier

PITR
  Point-In-Time Recovery (Continuous Archiving)

PL
  Procedural Languages (server-side)

POSIX
  Portable Operating System Interface

RDBMS
  Relational Database Management System

RFC
  Request For Comments

SGML
  Standard Generalized Markup Language

SNI
  Server Name Indication, RFC 6066

SPI
  Server Programming Interface

SP-GiST
  Space-Partitioned Generalized Search Tree

SQL
  Structured Query Language

SRF
  Set-Returning Function

SSH
  Secure Shell

SSL
  Secure Sockets Layer

SSPI
  Security Support Provider Interface

SYSV
  Unix System V

TCP/IP
  Transmission Control Protocol (TCP) / Internet Protocol (IP)

TID
  Tuple Identifier
Acronyms

TLS
   Transport Layer Security

TOAST
   The Oversized-Attribute Storage Technique

TPC
   Transaction Processing Performance Council

URL
   Uniform Resource Locator

UTC
   Coordinated Universal Time

UTF
   Unicode Transformation Format

UTF8
   Eight-Bit Unicode Transformation Format

UUID
   Universally Unique Identifier

WAL
   Write-Ahead Log

XID
   Transaction Identifier

XML
   Extensible Markup Language
Appendix M. Glossary

This is a list of terms and their meaning in the context of PostgreSQL and relational database systems in general.

**ACID**

*Atomicity, Consistency, Isolation, and Durability*. This set of properties of database transactions is intended to guarantee validity in concurrent operation and even in event of errors, power failures, etc.

**Aggregate function (routine)**

A *function* that combines (*aggregates*) multiple input values, for example by counting, averaging or adding, yielding a single output value.

For more information, see Section 9.21.

See Also Window function (routine).

**Analytic function**

See Window function (routine).

**Analyze (operation)**

The process of collecting statistics from data in *tables* and other *relations* to help the *query planner* to make decisions about how to execute *queries*.

(Don't confuse this term with the *ANALYZE* option to the *EXPLAIN* command.)

For more information, see *ANALYZE*.

**Atomic**

In reference to a *datum*: the fact that its value cannot be broken down into smaller components.

In reference to a *database transaction*: see *atomicity*.

**Atomicity**

The property of a *transaction* that either all its operations complete as a single unit or none do. In addition, if a system failure occurs during the execution of a transaction, no partial results are visible after recovery. This is one of the ACID properties.

**Attribute**

An element with a certain name and data type found within a *tuple*.

**Autovacuum (process)**

A set of background processes that routinely perform *vacuum* and *analyze* operations.

For more information, see Section 23.1.6.

**Backend (process)**

Process of an *instance* which acts on behalf of a *client session* and handles its requests.

(Don't confuse this term with the similar terms *Background Worker* or *Background Writer*).

**Background (process) worker**

Process within an *instance*, which runs system- or user-supplied code. Serves as infrastructure for several features in PostgreSQL, such as *logical replication* and *parallel queries*. In addition, *Extensions* can add custom background worker processes.

For more information, see Chapter 46.

**Background (process) writer**

A process that writes dirty *data pages* from *shared memory* to the file system. It wakes up periodically, but works only for a short period in order to distribute its expensive I/O activity over time to avoid generating larger I/O peaks which could block other processes.

For more information, see Section 18.4.5.

</table>
**Foreign data wrapper**  
A means of representing data that is not contained in the local *database* so that it appears as if were in local *table(s)*. With a foreign data wrapper it is possible to define a *foreign server* and *foreign tables*.

For more information, see [CREATE FOREIGN DATA WRAPPER](#).

**Foreign key**  
A type of *constraint* defined on one or more *columns* in a *table* which requires the value(s) in those *columns* to identify zero or one *row* in another (or, infrequently, the same) *table*.

**Foreign server**  
A named collection of *foreign tables* which all use the same *foreign data wrapper* and have other configuration values in common.

For more information, see [CREATE SERVER](#).

**Foreign table (relation)**  
A *relation* which appears to have *rows* and *columns* similar to a regular *table*, but will forward requests for data through its *foreign data wrapper*, which will return *result sets* structured according to the definition of the *foreign table*.

For more information, see [CREATE FOREIGN TABLE](#).

**Fork**  
Each of the separate segmented file sets in which a relation is stored. The *main fork* is where the actual data resides. There also exist two secondary forks for metadata: the *free space map* and the *visibility map*. *Unlogged relations* also have an *init fork*.

**Free space map (fork)**  
A storage structure that keeps metadata about each data page of a table’s main fork. The free space map entry for each page stores the amount of free space that’s available for future tuples, and is structured to be efficiently searched for available space for a new tuple of a given size.

For more information, see [Section 66.3](#).

**Function (routine)**  
A type of routine that receives zero or more arguments, returns zero or more output values, and is constrained to run within one transaction. Functions are invoked as part of a query, for example via *SELECT*. Certain functions can return *sets*; those are called *set-returning functions*.

Functions can also be used for *triggers* to invoke.

For more information, see [CREATE FUNCTION](#).

**Grant**  
An SQL command that is used to allow a *user* or *role* to access specific objects within the *database*.

For more information, see [GRANT](#).

**Heap**  
Contains the values of *row* attributes (i.e., the data) for a *relation*. The heap is realized within one or more *file segments* in the relation’s *main fork*.

**Host**  
A computer that communicates with other computers over a network. This is sometimes used as a synonym for *server*. It is also used to refer to a computer where *client processes* run.

**Index (relation)**  
A *relation* that contains data derived from a *table* or *materialized view*. Its internal structure supports fast retrieval of and access to the original data.

For more information, see [CREATE INDEX](#).
<table>
<thead>
<tr>
<th>Glossary</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Insert</td>
<td>An SQL command used to add new data into a table. For more information, see INSERT.</td>
</tr>
<tr>
<td>Instance</td>
<td>A group of backend and auxiliary processes that communicate using a common shared memory area. One postmaster process manages the instance; one instance manages exactly one database cluster with all its databases. Many instances can run on the same server as long as their TCP ports do not conflict.</td>
</tr>
<tr>
<td>Isolation</td>
<td>The property that the effects of a transaction are not visible to concurrent transactions before it commits. This is one of the ACID properties. For more information, see Section 13.2.</td>
</tr>
<tr>
<td>Join</td>
<td>An operation and SQL keyword used in queries for combining data from multiple relations.</td>
</tr>
<tr>
<td>Key</td>
<td>A means of identifying a row within a table or other relation by values contained within one or more attributes in that relation.</td>
</tr>
<tr>
<td>Lock</td>
<td>A mechanism that allows a process to limit or prevent simultaneous access to a resource.</td>
</tr>
<tr>
<td>Log file</td>
<td>Log files contain human-readable text lines about events. Examples include login failures, long-running queries, etc. For more information, see Section 23.3.</td>
</tr>
<tr>
<td>Logged</td>
<td>A table is considered logged if changes to it are sent to the WAL. By default, all regular tables are logged. A table can be specified as unlogged either at creation time or via the ALTER TABLE command.</td>
</tr>
<tr>
<td>Logger (process)</td>
<td>If activated, the process writes information about database events into the current log file. When reaching certain time- or volume-dependent criteria, a new log file is created. Also called syslogger.</td>
</tr>
<tr>
<td>Materialized</td>
<td>The property that some information has been pre-computed and stored for later use, rather than computing it on-the-fly. This term is used in materialized view, to mean that the data derived from the view's query is stored on disk separately from the sources of that data.</td>
</tr>
<tr>
<td>Materialized (relation)</td>
<td>A relation that is defined by a SELECT statement (just like a view), but stores data in the same way that a table does. It cannot be modified via INSERT, UPDATE, or DELETE operations.</td>
</tr>
</tbody>
</table>
For more information, see CREATE MATERIALIZED VIEW.

**Multi-version concurrency control**
A mechanism designed to allow several transactions to be reading and writing the same rows without one process causing other processes to stall. In PostgreSQL, MVCC is implemented by creating copies (versions) of tuples as they are modified; after transactions that can see the old versions terminate, those old versions need to be removed.

**Null**
A concept of non-existence that is a central tenet of relational database theory. It represents the absence of a definite value.

**Optimizer**
See Query planner.

**Parallel query**
The ability to handle parts of executing a query to take advantage of parallel processes on servers with multiple CPUs.

**Partition**
One of several disjoint (not overlapping) subsets of a larger set.

In reference to a partitioned table: One of the tables that each contain part of the data of the partitioned table, which is said to be the parent. The partition is itself a table, so it can also be queried directly; at the same time, a partition can sometimes be a partitioned table, allowing hierarchies to be created.

In reference to a window function in a query, a partition is a user-defined criterion that identifies which neighboring rows of the query's result set can be considered by the function.

**Partitioned table** (relation)
A relation that is in semantic terms the same as a table, but whose storage is distributed across several partitions.

**Postmaster (process)**
The very first process of an instance. It starts and manages the other auxiliary processes and creates backend processes on demand.

For more information, see Section 17.3.

**Primary key**
A special case of a unique constraint defined on a table or other relation that also guarantees that all of the attributes within the primary key do not have null values. As the name implies, there can be only one primary key per table, though it is possible to have multiple unique constraints that also have no null-capable attributes.

**Primary (server)**
When two or more databases are linked via replication, the server that is considered the authoritative source of information is called the primary, also known as a master.

**Procedure (routine)**
A type of routine. Their distinctive qualities are that they do not return values, and that they are allowed to make transactional statements such as COMMIT and ROLLBACK. They are invoked via the CALL command.

For more information, see CREATE PROCEDURE.

**Query**
A request sent by a client to a backend, usually to return results or to modify data on the database.

**Query planner**
The part of PostgreSQL that is devoted to determining (planning) the most efficient way to execute queries. Also known as query optimizer, optimizer, or simply planner.

**Record**
See Tuple.
Recycling
See WAL file.

Referential integrity
A means of restricting data in one relation by a foreign key so that it must have matching data in another relation.

Relation
The generic term for all objects in a database that have a name and a list of attributes defined in a specific order. Tables, sequences, views, foreign tables, materialized views, composite types, and indexes are all relations.

More generically, a relation is a set of tuples; for example, the result of a query is also a relation.

In PostgreSQL, Class is an archaic synonym for relation.

Replica (server)
A database that is paired with a primary database and is maintaining a copy of some or all of the primary database's data. The foremost reasons for doing this are to allow for greater access to that data, and to maintain availability of the data in the event that the primary becomes unavailable.

Replication
The act of reproducing data on one server onto another server called a replica. This can take the form of physical replication, where all file changes from one server are copied verbatim, or logical replication where a defined subset of data changes are conveyed using a higher-level representation.

Result set
A relation transmitted from a backend process to a client upon the completion of an SQL command, usually a SELECT but it can be an INSERT, UPDATE, or DELETE command if the RETURNING clause is specified.

The fact that a result set is a relation means that a query can be used in the definition of another query, becoming a subquery.

Revoke
A command to prevent access to a named set of database objects for a named list of roles.

For more information, see REVOKE.

Role
A collection of access privileges to the instance. Roles are themselves a privilege that can be granted to other roles. This is often done for convenience or to ensure completeness when multiple users need the same privileges.

For more information, see CREATE ROLE.

Rollback
A command to undo all of the operations performed since the beginning of a transaction.

For more information, see ROLLBACK.

Routine
A defined set of instructions stored in the database system that can be invoked for execution. A routine can be written in a variety of programming languages. Routines can be functions (including set-returning functions and trigger functions), aggregate functions, and procedures.

Many routines are already defined within PostgreSQL itself, but user-defined ones can also be added.

Row
See Tuple.

Savepoint
A special mark in the sequence of steps in a transaction. Data modifications after this point in time may be reverted to the time of the savepoint.
Glossary

For more information, see SAVEPOINT.

**Schema**
A schema is a namespace for *SQL objects*, which all reside in the same *database*. Each SQL object must reside in exactly one schema.

All system-defined SQL objects reside in schema `pg_catalog`.

More generically, the term *schema* is used to mean all data descriptions (*table* definitions, *constraints*, comments, etc) for a given *database* or subset thereof.

For more information, see Section 5.9.

**Segment**
See File segment.

**Select**
The SQL command used to request data from a *database*. Normally, `SELECT` commands are not expected to modify the *database* in any way, but it is possible that `functions` invoked within the query could have side effects that do modify data.

For more information, see SELECT.

**Sequence (relation)**
A type of relation that is used to generate values. Typically the generated values are sequential non-repeating numbers. They are commonly used to generate surrogate *primary key* values.

**Server**
A computer on which PostgreSQL *instances* run. The term *server* denotes real hardware, a container, or a *virtual machine*.

This term is sometimes used to refer to an instance or to a host.

**Session**
A state that allows a client and a backend to interact, communicating over a *connection*.

**Shared memory**
RAM which is used by the processes common to an *instance*. It mirrors parts of *database* files, provides a transient area for *WAL records*, and stores additional common information. Note that shared memory belongs to the complete instance, not to a single database.

The largest part of shared memory is known as *shared buffers* and is used to mirror part of data files, organized into pages. When a page is modified, it is called a dirty page until it is written back to the file system.

For more information, see Section 18.4.1.

**SQL object**
Any object that can be created with a `CREATE` command. Most objects are specific to one database, and are commonly known as *local objects*.

Most local objects reside in a specific *schema* in their containing database, such as *relations* (all types), *routines* (all types), data types, etc. The names of such objects of the same type in the same schema are enforced to be unique.

There also exist local objects that do not reside in schemas; some examples are *extensions*, *data type casts*, and *foreign data wrappers*. The names of such objects of the same type are enforced to be unique within the database.

Other object types, such as *roles*, *tablespaces*, replication origins, subscriptions for logical replication, and databases themselves are not local SQL objects since they exist entirely outside of any specific database; they
are called global objects. The names of such objects are enforced to be unique within the whole database cluster.

For more information, see Section 21.1.

SQL standard
A series of documents that define the SQL language.

Standby (server)
See Replica (server).

Stats collector (process)
This process collects statistical information about the instance's activities.

For more information, see Section 26.2.

System catalog
A collection of tables which describe the structure of all SQL objects of the instance. The system catalog resides in the schema pg_catalog. These tables contain data in internal representation and are not typically considered useful for user examination; a number of user-friendlier views, also in schema pg_catalog, offer more convenient access to some of that information, while additional tables and views exist in schema information_schema (see Chapter 35) that expose some of the same and additional information as mandated by the SQL standard.

For more information, see Section 5.9.

Table
A collection of tuples having a common data structure (the same number of attributes, in the same order, having the same name and type per position). A table is the most common form of relation in PostgreSQL.

For more information, see CREATE TABLE.

Tablespace
A named location on the server file system. All SQL objects which require storage beyond their definition in the system catalog must belong to a single tablespace. Initially, a database cluster contains a single usable tablespace which is used as the default for all SQL objects, called pg_default.

For more information, see Section 21.6.

Temporary table
Tables that exist either for the lifetime of a session or a transaction, as specified at the time of creation. The data in them is not visible to other sessions, and is not logged. Temporary tables are often used to store intermediate data for a multi-step operation.

For more information, see CREATE TABLE.

TOAST
A mechanism by which large attributes of table rows are split and stored in a secondary table, called the TOAST table. Each relation with large attributes has its own TOAST table.

For more information, see Section 66.2.

Transaction
A combination of commands that must act as a single atomic command: they all succeed or all fail as a single unit, and their effects are not visible to other sessions until the transaction is complete, and possibly even later, depending on the isolation level.

For more information, see Section 13.2.

Transaction ID
The numerical, unique, sequentially-assigned identifier that each transaction receives when it first causes a database modification. Frequently abbreviated as xid. When stored on disk, xids are only 32-bits wide, so only approximately four billion write transaction IDs can be generated; to permit the system to run for longer than that, epochs are
Transactions per second (TPS)  
Average number of transactions that are executed per second, totaled across all sessions active for a measured run. This is used as a measure of the performance characteristics of an instance.

Trigger  
A function which can be defined to execute whenever a certain operation (INSERT, UPDATE, DELETE, TRUNCATE) is applied to a relation. A trigger executes within the same transaction as the statement which invoked it, and if the function fails, then the invoking statement also fails.

For more information, see CREATE TRIGGER.

Tuple  
A collection of attributes in a fixed order. That order may be defined by the table (or other relation) where the tuple is contained, in which case the tuple is often called a row. It may also be defined by the structure of a result set, in which case it is sometimes called a record.

Unique constraint  
A type of constraint defined on a relation which restricts the values allowed in one or a combination of columns so that each value or combination of values can only appear once in the relation — that is, no other row in the relation contains values that are equal to those.

Because null values are not considered equal to each other, multiple rows with null values are allowed to exist without violating the unique constraint.

Unlogged  
The property of certain relations that the changes to them are not reflected in the WAL. This disables replication and crash recovery for these relations.

The primary use of unlogged tables is for storing transient work data that must be shared across processes.

Temporary tables are always unlogged.

Update  
An SQL command used to modify rows that may already exist in a specified table. It cannot create or remove rows.

For more information, see UPDATE.

User  
A role that has the LOGIN privilege.

User mapping  
The translation of login credentials in the local database to credentials in a remote data system defined by a foreign data wrapper.

For more information, see CREATE USER MAPPING.

Vacuum  
The process of removing outdated tuple versions from tables or materialized views, and other closely related processing required by PostgreSQL’s implementation of MVCC. This can be initiated through the use of the VACUUM command, but can also be handled automatically via autovacuum processes.

For more information, see Section 23.1.

View  
A relation that is defined by a SELECT statement, but has no storage of its own. Any time a query references a view, the definition of the view is
substituted into the query as if the user had typed it as a subquery instead of the name of the view.

For more information, see **CREATE VIEW**.

**Visibility map (fork)**

A storage structure that keeps metadata about each data page of a table’s main fork. The visibility map entry for each page stores two bits: the first one (**all-visible**) indicates that all tuples in the page are visible to all transactions. The second one (**all-frozen**) indicates that all tuples in the page are marked frozen.

**WAL**

See **Write-ahead log**.

**WAL archiver (process)**

A process that saves copies of **WAL files** for the purpose of creating backups or keeping replicas current.

For more information, see **Section 24.3**.

**WAL file**

Also known as **WAL segment** or **WAL segment file**. Each of the sequentially-numbered files that provide storage space for **WAL**. The files are all of the same predefined size and are written in sequential order, interspersing changes as they occur in multiple simultaneous sessions. If the system crashes, the files are read in order, and each of the changes is replayed to restore the system to the state it was in before the crash.

Each WAL file can be released after a **checkpoint** writes all the changes in it to the corresponding data files. Releasing the file can be done either by deleting it, or by changing its name so that it will be used in the future, which is called **recycling**.

For more information, see **Section 28.6**.

**WAL record**

A low-level description of an individual data change. It contains sufficient information for the data change to be re-executed (**replayed**) in case a system failure causes the change to be lost. WAL records use a non-printable binary format.

For more information, see **Section 28.6**.

**WAL segment**

See **WAL file**.

**WAL writer (process)**

A process that writes **WAL records** from **shared memory** to **WAL files**.

For more information, see **Section 18.5**.

**Window function**

A type of **function** used in a **query** that applies to a **partition** of the query's **result set**; the function's result is based on values found in **rows** of the same partition or frame.

All **aggregate functions** can be used as window functions, but window functions can also be used to, for example, give ranks to each of the rows in the partition. Also known as **analytic functions**.

For more information, see **Section 3.5**.

**Write-ahead log**

The journal that keeps track of the changes in the **database cluster** as user- and system-invoked operations take place. It comprises many individual **WAL records** written sequentially to **WAL files**.
Appendix N. Color Support

Most programs in the PostgreSQL package can produce colorized console output. This appendix describes how that is configured.

N.1. When Color is Used

To use colorized output, set the environment variable `PG_COLOR` as follows:

1. If the value is `always`, then color is used.
2. If the value is `auto` and the standard error stream is associated with a terminal device, then color is used.
3. Otherwise, color is not used.

N.2. Configuring the Colors

The actual colors to be used are configured using the environment variable `PG_COLORS` (note plural). The value is a colon-separated list of `key=value` pairs. The keys specify what the color is to be used for. The values are SGR (Select Graphic Rendition) specifications, which are interpreted by the terminal.

The following keys are currently in use:

- `error`
  used to highlight the text “error” in error messages

- `warning`
  used to highlight the text “warning” in warning messages

- `locus`
  used to highlight location information (e.g., program name and file name) in messages

The default value is `error=01;31:warning=01;35:locus=01` (01;31 = bold red, 01;35 = bold magenta, 01 = bold default color).

Tip

This color specification format is also used by other software packages such as GCC, GNU coreutils, and GNU grep.
Appendix O. Obsolete or Renamed Features

Functionality is sometimes removed from PostgreSQL, feature, setting and file names sometimes change, or documentation moves to different places. This section directs users coming from old versions of the documentation or from external links to the appropriate new location for the information they need.

O.1. recovery.conf file merged into postgresql.conf

Postgres Pro 11 and below used a configuration file named recovery.conf to manage replicas and standbys. Support for this file was removed in Postgres Pro 12. See the release notes for PostgreSQL 12 for details on this change.

On Postgres Pro 12 and above, archive recovery, streaming replication, and PITR are configured using normal server configuration parameters. These are set in postgresql.conf or via ALTER SYSTEM like any other parameter.

The server will not start if a recovery.conf exists.

The trigger_file setting has been renamed to promote_trigger_file.

The standby_mode setting has been removed. A standby.signal file in the data directory is used instead. See Standby Server Operation for details.

O.2. Default Roles Renamed to Predefined Roles

PostgreSQL 13 and below used the term “Default Roles”. However, as these roles are not able to actually be changed and are installed as part of the system at initialization time, the more appropriate term to use is “Predefined Roles”. See Section 20.5 for current documentation regarding Predefined Roles, and the release notes for PostgreSQL 14 for details on this change.

O.3. pg_xlogdump renamed to pg_waldump

Postgres Pro 9.6 and below provided a command named pg_xlogdump to read write-ahead-log (WAL) files. This command was renamed to pg_waldump, see pg_waldump for documentation of pg_waldump and see the release notes for PostgreSQL 10 for details on this change.

O.4. pg_resetxlog renamed to pg_resetwal

Postgres Pro 9.6 and below provided a command named pg_resetxlog to reset the write-ahead-log (WAL) files. This command was renamed to pg_resetwal, see pg_resetwal for documentation of pg_resetwal and see the release notes for PostgreSQL 10 for details on this change.

O.5. pg_receivexlog renamed to pg_receivewal

Postgres Pro 9.6 and below provided a command named pg_receivexlog to fetch write-ahead-log (WAL) files. This command was renamed to pg_receivewal, see pg_receivewal for documentation of pg_receivewal and see the release notes for PostgreSQL 10 for details on this change.
Bibliography

Selected references and readings for SQL and PostgreSQL.

Some white papers and technical reports from the original POSTGRES development team are available at the University of California, Berkeley, Computer Science Department web site.
